Weather conditions continue to interfere with mining operations in various parts of the State. While the intense cold no longer prevails, a succession of snowstorms, high winds, and thaws has added further difficulties to a season that has been unusually rigorous, even in the most favored districts. Tintic was cut off several days from the smelters through blockades on the railroads caused by snow-slides late in February. Some damage was reported in the district itself, where other

slides destroyed buildings and equipment. Park City was likewise cut off for a short time. The persistent shortage of coal reached alarming proportions in both districts, some curtailment of mining being caused thereby. The congestion of railroad traffic has also hampered the endeavors of the smaller operators to get their ore to market, and to obtain sorely needed supplies. Operations in the open pits at Bingham have been conducted under difficulties. The coal shortage was also felt here by some companies, and many individuals resorted to the parcel-post as a means of obtaining fuel.

In Little Cottonwood the South Hecla and Michigan-Utah continue to make heavy shipments. From the first of the year to the middle of February the latter had

shipped about 1000 tons of ore and had a further 800 tons at its tramway-terminal awaiting haulage to the railroad. The usual spring rumors of consolidations are being circulated. The most pretentious is the suggested consolidation of the South Hecla, Albion, Alta-Germania, South Hecla Extension, Alta-Michigan, Secret, Sells, and Peruvian mines, all situated on the south side of Little Cottonwood canyon, and extending into American Fork canyon. No official statement has been made public.

Dividends for the first six weeks of this year aggregate \$715,400, paid by six companies, three in the Tintic district, the Chief Con., Dragon Con. and Iron Blossom; the Moscow in Beaver county; the Silver King Coalition at Park City; and the Utah Metal & Tunnel at Bingham. This by no means represents the earnings available for distribution as many of the larger companies do not declare dividends until later in the quarter, notably Utah Copper, which makes payments at the present time as large as the rest combined.

Since the beginning of the year the Ohio Copper Co. has been operating its mine at Bingham on company account, under the same resident management that directed the work previous to the recent troubles and receiverships, emerging finally out of the hands of various committees of bondholders into the control of the stockholders. The mill is treating 2500 tons daily, but is said to be making only a 50% recovery for a monthly profit of \$30,000. There is a large tonnage of ore containing 0.9% copper available for treatment. A small test-plant is to be equipped with Janney and Minerals Separation flotation-machines, in an endeavor to increase the recovery. If the metallurgical problems can be solved there is reason to believe that Ohio Copper will yet justify early hopes.

Development of the oil-shale beds, to which reference was made in my last article, is threatened with extinction through the recent withdrawal order of the Federal Government which reserves thousands of acres of these shales for the use of the Navy.

The approaching completion of the Deep Creek railroad is stimulating activity in the Clifton and adjoining districts. It is said that much ore awaits shipment, claims are frequently changing hands, new townsites being laid out, new companies incorporated, and the district being given every opportunity to justify the claims of its sponsors, many of whom are among the most solid men of the State. The region has had the benefit of more competent examination and direction of affairs at the hands of capable engineers than any other, and so far is remarkably free from ill-considered flotations, both of which facts are greatly in its favor and lead to the expectation that it will reward the hopes of its friends.

The unusual profits of the metal mines and the aggravated coal-shortage have aroused a sentiment that is finding expression in the introduction of numerous radical and detrimental bills in the present session of the legislature. Most of the bills for taxation and regulation find a ready mark in the mining companies, and in

many cases are apparently aimed at them. Income-tax bills, mine-tax bills, compensation bills, land-board investigations, etc., all threaten to hit the mines seriously. First came a State income-tax bill that followed the schedule of the Federal law, but was finally reduced one-half throughout. As passed unanimously by the House it provides a tax of 1% on the total net income of corporations and a special tax of 50 cents for each \$1000 of fair valuation of its capital stock in excess of \$99,000. This bill, which adds taxes in addition to all the usual levies, is regarded as unnecessary and detrimental to the best interests of the State. There is no acknowledgment of the wasting assets of mines, making the bill peculiarly discriminatory. The bill has not yet passed the Senate, and the Governor has emphatically stated that he will veto it if it comes to him for signature. Its fate is therefore uncertain. The House has further passed a resolution calling for a constitutional amendment to provide for the taxation of mines "as other property," in other words, at full cash value, without supplying any machinery for determining that value. The experience of Michigan in taxing mines, even with the assistance of the best advice, is fresh in the memory of mining men. What the result of an attempted appraisal by a non-technical board of equalization, based on reports by equally poorly equipped assessors, will be, can only be left to the imagination.

Two compensation bills have been introduced. One is a very radical measure in the House to which all employers of labor take exception on the ground that it allows the employee to enter civil suit if he desires to waive the legal compensation, while at the same time depriving the employer of the defense of assumption of risk, the fellow-servant rule, etc. The bill introduced in the Senate was drawn by a commission appointed by the Governor two years ago, and embodies the result of a careful study of the laws of other States and the adoption of the best of their provisions. A compromise measure is expected.

The air-tight prohibition bill which goes into effect during the middle of the year is so far the sole contribution of the legislature to the welfare of the mining industry. The PRESS has described briefly the plan of the State Conservation Commission, working in conjunction with the University of Utah, U. S. Bureau of Mines, and American Mining Congress, to promote the mining industry, by aiding the prospector as well as investors in their search for mines. This work is likely to be greatly hampered and one of the most important features abandoned, since it is the general opinion that the Conservation Commission will be allowed to die when the terms of the present members expire shortly. The compilation of the resources of the State by the Commission was having an important effect on prospecting and excellent work was being done, which it is to be feared no other agency will be in a position to do as well.

The old mining districts of Little Cottonwood and American Fork are attracting increasing attention, and it is expected that the new activity will meet success.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

NEW MEXICO

RENEWED ACTIVITY IN THE IRON-MINING REGION.—ZINC MINING ACTIVE.

A RENEWAL OF MINING ACTIVITY IN THE PINOS ALTOS DISTRICT.

At Hanover and Fierro several hundred men are employed by the eight different operating mining companies. It is difficult for a stranger to get accommodations, the hotels and rooming-houses being crowded. It is reported that the U. S. Copper Co. plans to build a large hotel at Hanover this spring. The Santa Fe railroad is doing the biggest business in freight since the line was extended to Fierro.—The Colorado Fuel & Iron Co., which has mined and shipped iron ore for many years from Fierro, is employing 250 men. Ore is being mined from the Jim Fair and Snow Flake cuts at Fierro and from the Cupola property at Hanover. Shipments average 500 tons a day from the mines to the company's reduction works at Pueblo, Colorado. This company has been operating under lease from the Brock, Barringer, and Brockman interests for nearly 20 years, thousands of tons of high-grade iron ore having been shipped from the district.—The Hanover Bessemer Steel & Iron Co. (Brock, Barringer, and Brockman) is a new corporation formed to mine the properties that have been under lease to the C. F. & I. Co. and lately taken over by the new company. The company is operating in the Union Hill cut just above the new mill, and a mile of tramway has been completed from the Continental property adjoining the Union Hill. This tramway is laid along the crest of the ridge and ends at an incline 100 ft. above the mill, the cars being raised and lowered by cable. With the construction work under way and the work in the mines the company has about 200 men on the pay-roll. It is also learned that the Bessemer company will superintend the work at the Jim Fair, Snow Flake, and Cupola properties after June 1. An agreement has been reached with the C. F. & I. Co., the present lessees, to give up its lease and suspend operations at that time. The agreement provides for the contracting of all iron concentrate from the mill to the Colorado people. The new Bessemer plant is well under way, one unit of 400 tons capacity daily to be completed and ready for operation by May 1. All concrete foundations are in and the greater part of the frame work is up, and installation of machinery is progressing. The remainder of the equipment is arriving. Manager R. E. McKechnie says they will use the wet magnetic separators in handling their ores. The crusher-room will contain a 74-inch gyratory crusher and two sets of rolls, Traylor type. The ore will be transferred by belt-conveyor to bins in the main mill and fed to ball-mills and crushed to 60 to 80-mesh. The ore then goes to the wet magnetic separators. Two crude-oil engines of the La Vergne type have been received. The mill site is on the line of the Santa Fe railroad, on the Union Hill property midway between Hanover and Fierro.

The A. R. Davidson property north of the Jim Fair cut has produced three cars of 7% copper ore each week for the past two months. The Hanover Copper Co. owns 14 claims north-east of the Philadelphia group of the U. S. Copper Co. at Hanover, and is employing 30 men, mining 20 to 30 zinc carbonate and shipping two cars a week. The deepest pit is 100 ft., but is to be sunk to 300 ft. and then tapped by an adit 1000 ft. long driven in from the south. The equipment consists of an air-compressor operating 8 jack-hammer drills,

water Leyner type, and a 15-hp. Fairbanks-Morse gas-engine hoist. This property is owned by G. A. St. Clair of Duluth; his son R. G. St. Clair is in charge.

The Republic Mining & Milling Co., headed by William H. Janney and associates, is another recently organized company. It has acquired the Welch property lying east of the Empire Zinc concentrator at Hanover. Considerable rich zinc ore has been shipped from these properties. Development on an extensive plan is now under way; a new double compartment shaft is already down 150 ft. and will be continued to a much greater depth. Driving, cross-cutting, and blocking out ore to secure tonnage is the aim of the company. It is announced that one of the best metallurgists of the country is identified with the Republic people, who will have charge of the new mill now being planned for. It is also understood that experiments are now being conducted in an effort to evolve a treatment whereby zinc ore as low as 10 and possibly 5% can be treated at a profit. The ore is complex. Present plans call for the completion of a mill within six months.

The Chino Del Norte is yet another new company, with good properties near Fierro. Development is now under way.

The Empire Zinc Company at Hanover is increasing its production steadily, the new concentrator completed last year running full capacity. About 150 men are employed in the mines and mill. Speaking of the company's Cleaveland mill at Pinos Altos, where flotation is being added, Manager Schmidt stated that they are also considering putting in flotation at the Hanover plant. A second oil-engine of 250 hp. for needed power has been ordered and will be installed late in the spring. Shipment of concentrates averages better than 1000 tons a month, the crude ore mined being between 3000 and 3500 tons a month. Besides the mill product the company is making regular shipments of zinc carbonates.

A rich body of ore has been uncovered recently at the Philadelphia property of the United States Copper Co. at Hanover. Five feet of rich copper ore, assaying better than 15%, was cut into on the 70-ft. level at shaft No. 2. Development of this strike is being pushed, the company aim being to exploit different levels in both shafts, besides sinking shaft No. 1 to a depth of 1000 ft. The shafts have been re-timbered where needed and the head-frames put in first-class shape. The power plant is now in operation, as also the large air-compressor. The company expects to be employing a big crew by spring time. New surface improvements are planned for in the way of needed buildings, besides the new hotel planned for the town. While the company owns a sawmill, the recent bad spell of weather has made delivery of lumber slow. But the worst of the winter is over and from now on delay for timber will be a thing of the past. By next winter the company hopes to have conditions so improved that delivery of mining timbers and lumber will be prompt. The mill is of capacity sufficient to supply material to other companies operating in the district, not only Hanover, but at Pinos Altos also.

The future of the Hanover-Fierro district is safely assured. Average daily shipments are 15 cars and sometimes 20. The new companies reaching a producing state guarantee an immense tonnage from this district within the next twelve months.

Mining conditions in the Pinos Altos district are improving. The pay-roll for January was \$16,000. This includes the

Empire Zinc Co.'s Cleaveland mine and mill, and the El Paso Mining Co.'s properties and mill. The U. S. Copper Co. started operations last month. There is not an idle man in this camp. The Cleaveland mill of the Empire Zinc Co. is operating three shifts and shipping regularly. The installing of the flotation-plant is proceeding rapidly. The work of overhauling, repairing, and enlarging the El Paso Mining Co.'s mill was completed last week, and the mill is now running three full shifts. The addition of a ball-mill and the flotation process has more than doubled its capacity; it is expected to handle 75 tons per day. Six men are employed on each shift. The C. & O. Mining Co. expects to resume by the first of the month. For several months the company has only kept the mine unwatered. The main shaft is 200 ft. deep. The ore has been developed on the 100 and 200-ft. levels, and there is 70,000 tons of ore blocked out. It is said that the company will mill its ore at the El Paso Co.'s plant. At the Doyle-Clark, or Manhattan mine, development is progressing steadily. Shipments of a good grade of ore are being made from their Indian Hill property, which adjoins the Manhattan on the north-west.—At the Hardscrabble, taken over last December by the United States Copper Co., the first double-compartment vertical shaft is down 33 ft., with the bottom in ore assaying from $2\frac{1}{2}$ to 3% copper and 2 to 3 oz. silver. A second shaft will be started this week 600 ft. north of the first, which is known as the Owl, and the second as the Granite. Both shafts are within 100 ft. and south of the prospect shafts, from which high-grade ore and concentrating ore have been mined and shipped. In both prospect shafts three feet of high-grade copper and silver ore has been uncovered. Two air-compressors, 60 hp. each, have been ordered and are expected within the next 60 days. The compressors will furnish power to run jack-hammer drills, hoists, and pumps. Men are repairing and building roads to the saw-mill 12 miles distant. The roads are in bad condition. The company has contracted with Mexicans to deliver timbers both to the Pinos Altos and the Hanover properties. These Mexicans came from Mexico with Gen. Pershing's column, and have 180 head of stock, with good wagons and harness. The incline shaft of the Calumet-New Mexico Mining Company is down 200 ft. In the north drift, on the 100-ft. level, the face of the drift is in ore assaying 25% zinc, 20% lead, 8 oz. silver, and \$4.65 in gold, with a trace of copper. In the drift, on the 200-ft. level they are within 50 ft. of the same vein. Hand-drills are being used. This is not the vein on which the shaft was sunk, the latter being a 4-in. vein of quartz carrying 1.3 oz. gold, 12 oz. silver, 10% lead, 6.7% zinc, and 1% copper. A double-compartment vertical shaft is planned and the company also contemplates the erection of a small milling-plant.

BUTTE, MONTANA

SEMI-ANNUAL MEETING, MONTANA SECTION, A. I. M. E.

The semi-annual meeting of the Montana Section of the A. I. M. E. was held at the Silver Bow Club on Friday, February 2. An informal dinner was served earlier in the evening to 62 members and guests. Chairman J. L. Bruce called the meeting to order and talked on membership in the Institute, and the activities of the Naval Consulting Board. C. W. Goodale spoke regarding contributions for the relief of Belgian children, with an appeal to the members of the Institute to respond in appreciation of the work of H. C. Hoover.

The following officers were chosen for the year 1917: Chairman, W. C. Siderfin of Butte; vice-chairman, Oscar Rohn of Butte; secretary-treasurer, E. B. Young of Butte; executive committee, C. D. Demond of Anaconda and F. W. Bacorn of Butte.

An interesting paper was read by L. D. Frink, superintendent of the Speculator mine, upon 'Some Applications of Mine Ventilation in Butte.' Several exhibits and photographs showing the operation of the canvas-tubing, added to the value

of the talk. Discussion followed by Goodale, Bruce, Dunshee, Bacorn, Warner, and Simons.

F. A. Linforth, of the Anaconda mine geological department, exhibited a number of models and maps to show features in the graphic interpretation of geological problems. Discussion by B. H. Dunshee, of the A. C. M. Co., indorsed the value of such work to the mining department. He also gave an interesting account of his recent trip to the Hawaiian Islands. The secretary reported that the mailing list of the Montana Section now shows 202 names, a gain of 25 in the past year, with 15 applications for membership.

JOPLIN, MISSOURI

RETARDED PRODUCTION DUE TO A NUMBER OF CAUSES.—PROSPECTING NEW TERRITORY UNUSUALLY ACTIVE.

Never in the history of the district has there been a greater desire to maintain ore production at its maximum, but singularly enough, everything apparently has conspired to prevent this maximum being attained. Continued breakdowns of the electric power company's steam-turbine plants seriously have hindered all of those mines and mills dependent upon this source of power. In addition, with the company's hydro-electric plant not running even at 50% capacity, there has been a lack of rain and snow this season, and this has caused an overloading of the turbine-plants, hence the frequent stoppages of the steam-turbine plants. Anticipating normal conditions, the power company had undertaken to supply a large number of new mines and mills, and this has added to the difficulties of the situation. It has not been possible to replace electric-power plants with steam-power plants, as deliveries of machinery cannot be made under six to ten months, so that producers that are dependent upon electric power hesitate to attempt changing their plants, hoping that a normal condition may again obtain.

Nor have the steam-power plants been without difficulty. Those using gas for fuel have been cut off from the pipe-line owing to a shortage of gas, while those using coal found it difficult to maintain regular shipments and a supply of coal. As a result, even this class of mines is not holding up its production. Winter conditions also have interfered to an unusual degree; many mills have been frozen up from eight to ten days at a time, whenever a blizzard has come to the district.

In spite of these untoward conditions prospecting has been continued throughout the Kansas and Oklahoma fields. Many more acres of ground have been leased during the past month, and the United States is being scoured for prospect drill-rigs of the Keystone type to prospect new territory. Most of the leases are made upon the basis of drilling being started within 30 to 90 days and the difficulty in securing drills is a serious handicap in many instances for lease holders, although the situation now is fairly well understood by the land owners, and restrictions are being removed where cancellations of lease would have resulted. Every freight-train passing through that field is bringing in drill-rigs from all over the country, and the factory orders alone for new machines in that field are enormous. It is estimated that 300 drill-rigs are at work and the lease contracts will require as many more during the next 60 days if the contract obligations are fulfilled. Never before has there been such drilling activity in the history of the zinc-field. The results in the way of development in new territory are remarkable in its extent, and the richest type of ore yet developed in the district is being found. Some of the new mills in the Miami district, which have finally gotten down to a regular production, are actually turning out from 200 to 450 tons of concentrate per week, a record never dreamed of by the most optimistic operator of past years.

Extensions of the drilling are noted south of Galena, Kan-

sas, to the Oklahoma State line, and west of Badger-Peacock for six miles; also south-west of Melrose, Kansas, where the drilling for oil has shown the existence of zinc. Drilling in Kansas, therefore, reaches from the Oklahoma-Kansas State line five miles south-west of Melrose, Kansas, in a line north-east through Columbus and from a short distance east of Weir City, to a point one mile north of Waco, Kansas, on the State line between Missouri and Kansas. Within this three-cornered piece of the State of Kansas is centred 85% of the present drilling activity in the Missouri-Kansas-Oklahoma zinc-field. The remaining field of activity lies east of Waco, on the Missouri side and south of the Kansas line, in Oklahoma, extending from the State line south-west of Miami and south of the Neosho river.

TORONTO, ONTARIO

THE MILLS TO HAVE CYANIDE.—SATISFACTORY DEVELOPMENT OF MCINTYRE.

The production of the Porcupine district is being curtailed by a shortage of skilled labor, the supply of which is inadequate for the constantly increasing requirements of the plants. Another and still more threatening drawback, that for some time has been a cause of anxiety to mine-owners, has fortunately been avoided. Toward the close of 1916 the companies were notified by the Cassel Co. of Glasgow, Scotland, from which they have lately been receiving their cyanide, that they would be unable to continue the supply. However, efforts were made by Canadian representatives in Great Britain to procure a reversal of this decision. Last week the provincial Department of Lands and Mines received a cablegram from R. Reid, the Ontario government agent in London, announcing that the Cassel Co. would continue to furnish cyanide for Canadian mines. The Hollinger Consolidated is badly handicapped by adverse labor conditions. It is employing a force of 800 men, and, if they were obtainable, would take on 500 more. The opinion prevails that the present dividend will be cut in two, or, at all events, be considerably reduced, in anticipation of which the stock has shown a downward tendency, selling as low as \$5.09, or about \$2 below the high mark of last year. The company, since the merger, has been forced to keep production at a maximum to maintain its regular dividend of \$246,000 every four weeks, and the completion of the addition to the mill has been unavoidably delayed. It is considered that with the increasing cost of labor and materials, a continuation of the present dividend would be economically unsound. During January the Dome Mines produced bullion to the amount of \$181,000 from the treatment of 89,600 tons of ore, of the average value of \$4.57, at an operating cost of \$2.81 per ton. With the present advance in the cost of labor and materials, the slight increase in working cost of only 4c. per ton, in comparison with the figures for January 1916, is regarded as a satisfactory showing. The annual statement of the Dome Lake shows the total revenue was \$18,663, and expenditures \$111,451. Owing to extensive development work, the mill was only operated a short time during the year. The installation of a Hardinge ball-mill will bring the mill capacity up to 200 tons per day.

The McIntyre milled 14,317 tons of \$10.60 ore in January and produced bullion to the value of \$145,297. The average monthly production during the last quarter of 1916 was \$118,764. The new 600-ton mill is running smoothly, though not yet up to full capacity. The management, following the example of the Hollinger and Dome, will hereafter make regular monthly reports of production and tonnage. Stations have been cut in No. 5 shaft at the 700, 800, and 900-ft. levels and cross-cutting is under way. Large orebodies have been opened at the Davidson. The main vein on the 100-ft. level is 55 ft. wide, 5 ft. of which is stated to be high-grade. A separate orebody has been opened at the 200-ft. level, the vein being 35 ft. wide. On the 300-ft. level mineralization extends over a wide

area, a cross-cut shows vein-matter for 187 ft., a section of which 5 ft. wide is said to run \$50 per ton. At the Schumacher, developments at the 200-ft. level are highly satisfactory. An outcropping vein north of the shaft has been cross-cut for 7 ft. with the face still in ore. Diamond-drilling on the western half of the Newray has encountered a 4-ft. vein showing gold at a depth of 104-ft.—A small plant is being installed at the Nighthawk property and developments will be started.

The power-transmission line of the Northern Ontario Light & Power Co. to the Kirkland Lake district has been completed and is being tested. It has a capacity of 5000 hp., which is sufficient to supply the needs of the district for some time to come. Active operations will now be started on several properties that have been waiting for months for the promised power.

Further discoveries have been made at the 1600-ft. level of the Beaver Consolidated. Another high-grade vein running parallel to the first has been found at this depth. Its width is not known. Between the two there is 7 ft. of wall-rock heavily impregnated with native silver. The Temiskaming is sinking to the lower contact, which will shortly be reached, when it will connect with the Beaver workings, and continue sinking for an additional 200 ft. The Shamrock, adjoining the Beaver on the north, is in line with the strike and as soon as the work can be financed it will also sink to the 1600-ft. level. The Hargrave has struck a new vein of high-grade ore at the 75-ft. level in No. 1 shaft, from which it is shipping ore stated to carry over 2000 oz. per ton. The vein is 4 to 8 in. wide, with mineral extending into the wall-rock.—The production of the Nipissing during January was estimated at \$282,698, being larger than the output for any month since July last. Profits for the month are estimated at \$195,989.—The Kerr Lake produced 215,206 oz. in January.—The new vein recently discovered on the 800-ft. level of the Crown Reserve is showing well under development. The silver content will run high over 4 in. of the vein, the remaining 15 in. is comparatively low-grade. The annual report of the Trethewey shows that the mine, which had been closed but was re-opened and operated during the last seven months of the year, realized a profit of \$64,664 and that with the returns from the sale of silver on hand from the previous year the company made a total profit of \$79,865.—The Callow oil-flotation process is in successful operation at the Coniagas. The plant has a capacity of 150 tons daily.—At the Apex a highly mineralized 5-ft. vein has been cut at 900 ft. by diamond-drilling. The Gowganda Power Co., in which Philadelphia and Buffalo capitalists are largely interested, has initiated a hydro-electric power-development scheme in aid of the silver mining industry. The power-house will be at the South end of the Gowganda lake, and a dam will be built at Hanging Stone falls, on the east branch of the Montreal river. It is proposed to develop 1500 hp., in three units of 500 hp. each. The total cost will be about \$300,000.

COBALT, ONTARIO

A NEW VEIN DISCOVERED IN THE BEAVER CONSOLIDATED AND HIGH-GRADE ORE IN THE CROWN RESERVE.

A second high-grade silver vein has been encountered at the 1600-ft. level of the Beaver Consolidated. These two veins are in the Keewatin formation that underlies the diabase in this part of the Cobalt silver area. Less than eight feet of rock separates the two veins and this also carries considerable native silver, assays running about 100 oz. per ton. The veins are from six to eight inches wide and carry upwards of 1000 oz. silver per ton.

The old Crown Reserve mine, which has paid over \$6,000,000 in dividends in the past ten or twelve years and which was generally believed to be nearly worked out, has cut a 6-in. high-grade vein at the 800-ft. level, in territory that has been

considered unpromising. This development may add a number of years to the life of the Crown Reserve.

The Callow oil-flotation system recently installed at the Coniagas is returning a much higher recovery than was anticipated. The loss in silver is now reduced to less than one ounce per ton.

SPOKANE, WASHINGTON

THE NORTH-WEST MINING CONVENTION.

The North-West Mining Convention was held at Spokane from February 19 to 25, under the auspices of the Spokane Mining Men's Club and the Spokane Chamber of Commerce. The program was arranged by the Spokane Engineering and Technical Association, aided by the local sections of the A. I. M. E., A. I. E. E., and the A. S. C. E. The acknowledged success of the convention was due in great part to the tireless efforts of G. B. Dennis, president of the North-West Mining Association, F. C. Bailey, its secretary, and L. K. Armstrong, chairman of the program committee, and to J. L. Paine, president of the Spokane Chamber of Commerce. More than 600 men were present. The U. S. Bureau of Mines was represented by D. A. Lyon, and the American Mining Congress by Henry Mace Payne of New York. Henry Landes, State geologist, represented Washington.

A large and representative collection of ores was on exhibition from many mining districts of the North-West. These included collections of copper ores from Michigan, and of silver and associated metals and minerals from Cobalt, Ontario; copper ores from Montana; representative ores from Nevada; gold ores from central Idaho, and silver, lead, zinc, and antimony from the Coeur d'Alene district of that State, and a varied collection from Bonner's Ferry district in the northern part of the Panhandle. There were good displays from Chewelah, Boundary, Keller, Methow, and other mining districts in Washington, and a large display from Rossland, Nelson, Ainsworth, Slocan, Boundary, and other parts of southern British Columbia. Among the ores that attracted most attention were tungsten and scheelite from Murray district, Idaho, and magnesite from the deposits lately discovered near Valley, Washington, by F. M. Handy, of the State College of Washington, at Pullman. A miniature electric-arc furnace designed by C. G. Warfel, assistant professor of metallurgy in the mining engineering department of the Washington State College, at Pullman, was shown in operation twice each day during the convention. It made a fair grade of steel from small charges of iron ore from Stevens county, Washington.

Frank A. Ross read a paper on 'The Pacific North-West Minerals in Peace and in War.' Henry Landes, State geologist of Washington, told of the work under his direction in that State, and urged the mining men to give his department their support in securing the necessary legislation and adequate appropriations. E. M. Murphy presented a paper on 'The Application of Electricity to Mining,' illustrating his subject by means of stereopticon views. F. W. Isham talked of his experiences in Alaska, also employing the stereopticon for the purpose of illustration. Montgomery Shugg, of Seattle, gave an illustrated talk on 'The Manufacture and Uses of Pure Iron,' and O. P. M. Goss, also of Seattle, took for his subject 'Some Developments in Timber Construction.' In connection with the latter talk it was shown how, under a new system, Douglas fir is used in such a way as to secure greater strength than under old methods, besides reducing the fire-risk. Modern methods of treating timbers with creosote to preserve them were illustrated—in particular, the heavy timbers used in mines, warehouses, store-buildings, and bridges.

With J. W. Turner as chairman, Thursday was Miners' and Prospectors' Day, and included entertaining talks by two or three old prospectors, chief among whom was Lew Wilmot, of Spokane, whose prospecting activities were commenced more than half a century ago, and who had some interesting stories

to tell of placer-gold mining in various fields. Among other experiences he told of the arrival of the mail in the Clearwater country, Idaho, many years ago, when the miners had to pay \$1 for each letter brought to them, and \$1.25 per copy for the *Portland Oregonian*. He described the progress made in the use of placer-mining appliances from the primitive pan at first used, through the stages of the improved gold-pan, rocker, tom, sluice-box, and on to the time when 'giants' came into use in hydraulicking. Morris B. Parker, of Los Angeles, read a paper on the 'Mineral Resources of Methow, Washington,' which comprised a conservative and comprehensive survey of the resources of the Methow valley, together with notes on the geology and mineral resources of that region. Professor Arthur Lakes, of Nelson, B. C., read a paper on 'Fissure Veins.'

Among those who gave short talks at the luncheon on Thursday was Robert F. McElvenny, general superintendent for the Tacoma Smelting Co., who, speaking of the production and uses of copper, pointed out how much of this metal is used in ways that little is generally known. For instance, a surprisingly large quantity is used in frames around windows; millions of pounds in small bars go into storage batteries; much is used in german silver for such purposes as cans and shaving-stick tubes. Mr. McElvenny added that while smelter-men although students of the situation, know little of the outlook for copper, it was his personal view that the European war will be a long one, with copper in good demand while it lasts, but he thought there will be a sharp break at the conclusion of peace, then reconstruction and a recovery to better metal prices, to be followed by a comparatively high price for several years.

Russell Collins spoke of mining in the Coeur d'Alene region, and Professor Arthur Lakes expressed the opinion that there are still plenty of opportunities for discovery and development of new mining fields in British Columbia.

The Thursday afternoon session, under the auspices of the local section of the American Society of Civil Engineers, with Morton Macartney in the chair, was a symposium on cement and concrete. The papers presented were 'A Brief Outline of the Specifications for Cement and Cement-Concrete Aggregates,' by A. D. Butler, of Spokane; 'Cement Testing,' by J. P. Maider, of Spokane; 'Concrete in Pavements,' by C. R. Ege, of the Portland Cement Association, and 'Concrete in Highway Construction,' by H. J. Doolittle, assistant engineer of the Washington State Highway Department.

COLUMBIA SECTION A. I. M. E.—On Friday morning many of the visitors attended the Spokane Stock Exchange during the regular call. At noon there was a large attendance at luncheon, Spokane business men being the hosts. Short talks were given by M. C. Butler, M.E., of the Colliery Engineering Co., Seattle, Washington; William W. Elmer, of Portland, Oregon; T. Z. Humphrey, of the Anaconda Copper Mining Co.; and Prof. E. K. Soper, of the University of Idaho. The afternoon session was under the auspices of the Columbia Section of the American Institute of Mining Engineers, with the chairman of the section, W. H. Linney, of Spokane, in the chair. The mining engineering department of the State College of Washington, at Pullman, Wash., was represented by Francis A. Thomson, head of the department; C. G. Warfel, assistant professor of metallurgy; Solon Shedd, professor of geology. The University of Idaho was represented by R. R. Goodrich, professor of metallurgy, and E. K. Soper, professor of mining engineering.

Professor F. A. Thomson, head of the Department of Mining Engineering, State College of Washington at Pullman, made an interesting address on flotation concentration, and Dr. R. E. Goodrich, Professor of Metallurgy at the University of Idaho, at Moscow, related his experience in the concentration of tungsten and gold from ores of the Murray mining district of Idaho. Progress at the Bunker Hill & Sullivan smelter formed the topic of an interesting paper by M. H. Sullivan, superintendent of the smelter.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

Two thousand five hundred pounds of placer gold, valued at \$550,000, from the Iditarod district, arrived at Seward on January 9 for shipment to Seattle. It was transported on four dog-sleds from the Iditarod to Forty-Mile station on the Government railroad, where it was met and brought to Seward by special train. The trip of 500 miles from Iditarod to Forty-Mile station was made without mishap to any of the party.

JUNEAU. January returns from the mines on Douglas Island are officially stated as follows: Alaska Treadwell—29,554 tons crushed, producing \$66,925.80 at a net profit of \$30,846.64. The yield per ton was \$2.26. Alaska United—52,934 tons crushed, producing \$98,824.07. Average value of ore \$1.97 at the Ready Bullion mine and of \$1.86 at the 700-Foot mine. The Alaska Mexican crushed 10,395 tons, producing \$16,090.68, at a loss of \$1488.62.

ARIZONA

(Special Correspondence.)—The Big Jim Mining Co. at Oatman will build a 400-ton ore-mill, and the Gold Ore Mining Co., also at Oatman, will build a 50-ton mill. Ball-mills will be used instead of stamps for crushing, and pebble-mills for fine-grinding.

Oatman, February 24.

(Special Correspondence.)—The main shaft of the Nellie mine is down 385 ft. and has cut 32 ft. of quartz. Grab samples the last three rounds increased from \$7.90 to \$11 per ton. Sinking will be continued through the vein, which is 50 ft. wide, to 500 ft. The vein dips at 45°.—Charles Oster, of New York, is concluding the purchase of the Arizona-Rand and other groups covering a large acreage at Union Pass. This is a district of old producers, among the most prominent of which are the Sheep Trail, owned by the Sutro estate, and the Frisco. The Banner Gold in the same locality is down 250 ft. on the Sheep Trail vein in ore averaging \$10 gold per ton.—Paul C. Thorne and J. A. Small, of Oatman, and R. A. Brundage, of Kingman, have incorporated the Mandalay Gold Mines company to develop six claims adjoining the Banner Gold. Mr. Small is cashier of the bank of Oatman.—Robert Franke, a mining engineer representing J. Parke Channing, has finished an examination of properties in the Black range, where Channing and associates are developing the Oatman Syndicate property. C. H. Palmer, Jr., of Los Angeles, has inspected the Adams and Sunnyside properties in the Black range. He made the first report on the United Eastern to Seeley W. Mudd, Philip Wiseman, and Frank Keith, when that property was presented for their consideration.

Oatman, February 24.

CALIFORNIA

(Special Correspondence.)—The stockholders of the Springfield Tunnel & Development Co., operating near Columbia, in Tuolumne county, will on March 10 vote upon a proposition to increase the capital stock of the corporation from \$500,000 to \$1,000,000.

W. L. Schmidt and W. H. Cone, of San Francisco, have assigned to Frank W. Hyland, of the same city, their option to purchase certain magnesite mines situated near Chinese Camp. Mr. Hyland is to pay royalties of 75c. and 25c. per ton of ore taken from the property, and is to deliver at the Quinn siding, on the Sierra railroad, magnesite ore for the Sedan Calcined Magnesite Company.—An Oakland company, of which Eugene Schmitz, of San Francisco, is president, has taken a bond

on a magnesite mine owned by Henry Sims, situated a few miles from Chinese Camp. A hoist is to be installed at once.

The shaft at the Garfield mine, near Tuolumne, and on the south side of the North Fork, is to be sunk an additional 100 feet.

The water in the Columbia Basin, which was encountered several days ago, has been rising steadily despite continuous pumping at the rate of 600 gal. per minute. As a result work was discontinued on February 23, and the pump taken out.

Sonora, February 24.

(Special Correspondence.)—The Afterthought mine at Ingot is preparing to start up shortly. Twelve men are employed fixing the cars, tracks, and bridges. The mine has been unwatered to the 600-ft. level, where last spring was uncovered a large body of good-grade ore.—The Donkey mine, which recently was taken under a bond by the Mammoth Mining Co., is a mile and a half from Ingot. Nine men are erecting a head-frame. The new hoist was shipped from Kennett a week or so ago, and already is in place. Unwatering the shaft will be commenced within a week. Things look good for the district the coming spring.

Ingot, February 24.

(Special Correspondence.)—Thomas Lane is developing the old Lane & Tulloch mine three miles south of Angels. The mine is on the Mother Lode, a short distance north of Chaparral Hill. Considerable work was done on the property years ago by the former owners, and the prospect has been generally considered a most promising one. Sinking is in progress.

Angels, February 26.

(Special Correspondence.)—Construction of the electrolytic zinc plant of the Mammoth Co. is nearly finished, and it is reported the first run will be made early in March. At the smelter approximately 950 tons of ore is smelted daily, including 300 tons for the Balaklala mine, of the First National company. This summer heavy output will be made from the Stowell, Friday-Lowden and other properties acquired by the Mammoth company in the last three years. Fluxing ore for the smelter is largely drawn from the Reid mine, near Whitehouse. The ore is sent across the Sacramento river by an aerial tramway. Harvey Sallee is superintendent.

The Tom Greene group of three claims, at French Gulch, has been acquired by the Warren-Barnes company and preparations are being made for early operation. Some rich quartz was mined near surface in early days, and considerable milling-grade ore is in sight.

The Gardella Dredging Co. announces that two dredges of the latest type will be built this summer. They will distribute soil over the tailing, leaving the ground in fertile condition after dredging. No. 1 boat is dredging rich gravel on Clear creek, four miles below town.

Redding, February 27.

(Special Correspondence.)—During 1916 a total of 1600 cars of magnesite, worth approximately \$800,000, was shipped from Tulare county. Of this amount more than 80% was from the Porterville district, while fully 90% was handled through companies operating at Porterville. At present from 10 to 15 cars of magnesite is being shipped daily from Porterville, about one-half of which is calcined. The aggregate value of the ore going out from Porterville daily is about \$7000. With the opening of spring, when the roads are in better condition, it is

expected the daily output will reach \$10,000. There are three companies operating magnesite-calcining plants in this district; the Tulare Mining Co., 12 miles east of Porterville, the Porterville Magnesite Co., whose plant is three miles north-east of the city, and the plant of the American Magnesite Co., situated in the city, the latter completed last fall, and which has been kept busy ever since in filling a contract with the American Refractories Co. The plant of the American Magnesite Co. is the largest of its kind in the United States. It cost \$40,000 and embodies the latest ideas in equipment. The rotary kilns, 50 and 75 ft. long, the crushers, elevators, conveyors, and practically all parts of the plant, are operated by electric motors, which combined require 83 hp. A carload of oil is used every three days in the calcining-kilns, which are kept in operation day and night. About 35 men, working in three shifts of eight hours each, are employed at this plant, that alone is handling about 100 tons of raw ore per day.

Porterville, March 1.

The State Mining Bureau reports for the week ended February 24 that 25 new oil wells were started during the week; 18 wells to be inspected for the test of water shut-off; 17 wells are being drilled deeper, and nine are to be abandoned.

COLORADO

LEADVILLE. The strike at the Ontario tunnel in Iowa gulch becomes more important with development, according to reports received from the property. The ore-shoot is exposed for 40 ft. in the roof and floor of the tunnel and is strong in the breast with every indication of continuing to the site of the old Tiger shaft. It is believed that the ore-shoot in the tunnel is not the same as that opened from surface by the Tiger shaft, although it is in the same vein, which is said to be 100 ft. wide at surface. Cross-cutting is expected to expose another shoot.

Driving along the hanging wall is being pushed as rapidly as possible that a large section of the vein may be opened before shipping is commenced. The present condition of the roads to the property makes it impossible to haul ore, but it is believed that shipping can be started about the last of March, when, with some work, the roads can be improved. Mining men who have visited the property since the strike are unanimous in rating it as the biggest discovery made in the district in the last ten years and many state that it will develop into the largest mine that has been uncovered during the last twenty-five years.

Lessees on the Bartlett tunnel on Sugar Loaf are shipping a steady tonnage of silver ore from the vein recently opened through the winze near the breast of the tunnel. The development that has been accomplished on the ore-shoot shows it to be large and persistent. Operations will continue on a moderate scale until spring, when it is planned to install new machinery and make other necessary preparations for a heavy output.

The lessees that recently cut the old Fortune vein below the level of the Yak tunnel are experiencing trouble from a strong flow of water that was encountered in the ore-shoot and which tasks the capacity of the new electric pump. Development in the ore proceeds slowly, and a considerable tonnage has been extracted. It is believed that the water will gradually be drained by continuous pumping and will permit more extensive operations to be undertaken.

The sinking of the Jamie Lee shaft on Fryer hill is progressing favorably under contract, according to reports. Three shifts are employed in the shaft and are gaining depth at the rate of about four feet per day. What is believed to be the parting quartzite was cut recently and the shaft bottom is now in an underlying formation that is expected to be replaced by contact material at any time. A total depth of 60 ft. has been gained since sinking started a few weeks ago. Development in the upper workings of the Jamie Lee and other properties of

the Leadville unit has exposed several new small bodies that are encouraging and indicate the presence of more extensive shoots in the territory.

A new leasing company of local mining men has taken charge of the Denver City property on Yankee hill and is preparing to resume operations. Under the supervision of Ike Jones, the machinery is being overhauled. Work underground will be started as soon as the equipment is ready.

Work has been resumed in the Bullion King mine at Silverton. The main adit is in over 1400 ft. At 950 ft. from the mouth a cross-cut has been driven west for 1800 ft. Finding nothing of value, a drift was started south from the cross-cut 750 ft. from its beginning at the adit and at 490 ft. from the cross-cut a mass of high-grade ore was found, and several carloads of ore was shipped at good profit. The new work is under the direction of Martin Tully.

During February ore shipments from Silverton were unusually heavy. The Sunnyside mine sent out 22 cars in 20 days, the Iowa-Tiger 19 cars, and Silver Lake 16 cars. The total shipments for the first 20 days of the month reached 136 carloads.

MICHIGAN

The Athens mine, at Negaunee, property of the Cleveland-Cliffs Iron Co. is to be provided with a pumping-plant, the biggest and most complete to be found anywhere for this kind of service. This pumping-engine will be a motor-driven, vertical lift of 2400 ft. It will be operated by an electric motor of 400 hp., current to be supplied from the company's electric system in which power stations are maintained at Dead River, Marquette, and Au Train. This pumping-plant will be built by the Prescott company, of Menominee, and will require six months to complete. It will also take a similar time in which to secure a motor. Work of cutting a station in the Athens shaft for the reception of the plant is under way.

MISSOURI

The digging of a well on a tract of land east of Center creek last November resulted in the opening of one of the most promising silicate properties in the district. The find was made in a district where zinc-ore mineralization was not anticipated. Silicate ore was encountered at a depth of 11 ft., and immediately the potential possibilities of the district became apparent. A company was organized and shaft sinking started. Developments from the first were so promising that by the time the shaft was nearing completion it was decided a small mill was warranted, and one has been erected and is in operation, turning out high-grade silicate at a rate of 40 tons per week.

The company is known as the M. M. & B. Mining Co., and principally interested are John and James Morgan of Duenweg, who have had experience in silicate mining. They believe the prospect for the development of a rich new field is good. The ore is found in a hard formation and is all mill-dirt, being somewhat similar to that of the silicate mines just south and south-east of Duenweg.

The lease consists of twenty acres. Operations are being conducted at a depth of 35 ft., but the shaft sinking showed that the ore persists to 75 feet.

MONTANA

The Bulwer and Elkhorn Queen are each shipping regularly to the smelters and the outlook for a large tonnage being sent out is good. At the old Elkhorn mine nothing is being done, but effort is being made to keep the dump from getting wet and freezing, which indicates that there is a project on foot for treating the dump. There are many thousands of tons of ore that carry silver and some lead, and with present methods the belief is that it can be made to pay. The property is owned by the Walkers of Salt Lake City. The report is that

the Walkers will resume mining at the Elkhorn before a great while and that the old property will again be opened and worked on an extensive scale.

For a mine that has been 'worked out' more than twice, the Elkhorn Queen is giving a good account of itself. There are ten men employed stoping ore from the drift at the 300-ft. level. They are working on what is considered part of an old shoot that was overlooked by former operators. The pay-streak is said to be 30 ft. wide and 60 ft. deep. The ore is sent to the East Helena smelter. When this shoot is exhausted the lessees intend to search the slate contact to find more pay ore. The old works were confined exclusively to the lime rock adjacent to the contact where the big pocket was found. The Bulwer mine is also shipping pay ore regularly.

After driving a tunnel through porphyry and slate on a mining claim at the head of Three Miles west of Helena, the Gilmores have found good ore in a drift from the bottom of a winze 200 ft. beneath the surface. The ore in the drift from the bottom of the winze is four inches wide and consists of carbonate of lead slightly colored with copper carbonate. Assays from this ore for silver and gold gave returns of 300 oz. silver and \$12 in gold, with 40% lead.

L. L. Price, Jr., of the Original Bannack Mining Co., operating in the Bannack district reports a find of sulphide ore in the cross-cut from the Washington shaft on the 153-ft. level. Mr. Price said that they reached the orebody for which they had been cross-cutting for the last two months. The ore runs about 6% copper. In the Pioneer drift there has been opened a 30-ft. body of shipping ore and seven men are working on this drift. Ore-hauling by auto-trucks is being carried on day and night, each truck making six trips every 24 hours to the railroad station at Grant. The average haul of the two trucks has amounted to a car of ore per day. Two more trucks have arrived at Dillon and the output will now be four cars daily.

NEVADA

(Special Correspondence.)—The small town of Packard, situated four miles from Rochester, is attracting attention. It is the headquarters of the newly formed Rochester Combined Mines Co. A new town-site has been laid out adjacent to the old town of Packard, and the work of building has begun. A post-office will probably be established within a few weeks. By the purchase of the Eppelheimer group, where some silver-lead ore has been opened up, the holdings of the Combined Mines Co. have been increased to 84 claims. A 6-drill portable compressor has been installed and stoping begun on the Shepherd and Packard North Extension groups. This compressor is to be replaced by a larger one as soon as obtainable, and the portable outfit will be used to prospect other parts of the property. The motive power is furnished by a portable Diesel engine. Although power-lines run into the camp, supplying the Packard Co., it is the belief of the management that Diesel engines will furnish power at a cheaper rate, and this type will be used. The construction of the first unit of the proposed 600-ton cyanide-plant will be started as soon as supplies can be obtained. The present force of 20 men is to be increased to 100. J. W. Wilkey is superintendent.

Under the management of Jay A. Carpenter, plans are being made to work the Packard on a more extensive scale. The company has a large tonnage of ore blocked, and it is probable that the mill capacity will be increased to 150 or 200 tons daily. The present mill is handling 100 tons daily. The 120-D tunnel has advanced 900 ft. along the contact, and the 160-D, which is 80 ft. lower on the dip of the vein, is being pushed forward to reach the ore. The vein is a replacement-deposit in silicified and schistose rhyolite lying along a contact of flow-rhyolite and rhyolitic tuff. The latter was formerly mistaken for shale, which it greatly resembles. The value of the ore is almost entirely in silver, the gold content averaging less than 3c. per oz. of silver contained. Very little timber is required in mining

the orebodies in this district. Total costs for mining, milling, and development for the past year have averaged under \$5 per ton at the Packard, with better than 90% recovery.

As soon as the snow is off, work will be started on the Packard Extension group, adjoining the Packard on the south. These claims cover the southern end of a line of silicified rhyolite outcropping locally called dikes. These form a prominent feature of the topography of the district. They can be traced through the claims of the Rochester Mines Company, the Combined, and the Packard, and are intimately associated with the ore-deposits.—The new tramway of the Rochester Mines Company is about ready for use. Cold weather and delayed machinery prevented its completion. The new addition to the mill is in operation, increasing the capacity to over 200 tons daily.—Development work progresses steadily at the Merger, Nenzel-Crown Point, and United mines. The latter property has shipped several cars of medium-grade gold ore taken from shallow workings.

Prospecting is active around Lower Rochester, but no important discoveries have been made. The Winnemucca Mountain cyanide plant was shut-down recently, only a few months after beginning operations, due to a shortage of cyanide. The larger properties are protected by contracts.

Packard, February 25.

(Special Correspondence.)—Weather conditions have been bad, during the past 10 days, but the Nevada Consolidated Co. has been able to keep close to a normal production, shipping 50 tons per day of carbonate ores from its stock-pile to the smelter at Salt Lake City. This ore is high in silica. The Coppermines Co., by using a large amount of wood (from its own properties) together with some coal, has been able to keep the mill running on part time. The company has not yet accepted the mill. The General Engineering Co., of Salt Lake City, built it on contract and is now trying to get the saving up to standard. Several cars of concentrate have been shipped to the smelter at McGill; the Nevada Consolidated having made arrangements to smelt it.—The Boston-Ely, by its agent, H. S. Williams, is selling its surface equipment, after having spent over \$150,000. A shaft was sunk 1200 ft. and a drift run to a vein 30 to 40 ft. wide. A winze was sunk 45 ft. to water-level, but as the flow of the water was heavy they went up on the 1100-ft. level and spent \$50,000 driving and diamond-drilling to find a vein 600 to 800 ft. away that dipped from them. The only chance for a mine, in all probability, was below the water-level in the winze, in the sulphide zone. It was managed by a Boston stock-broker.—Superintendent Campbell, of the Ely Consolidated, has had to abandon, for the present, pumping from the Zack shaft. He will wait until the surface water from the melting snow runs off, and then install a large Cornish pump.—Lane Pearl, superintendent of the Ward mine lease, is ready to ship 50 tons per day to the Salt Lake smelters, as soon as the condition of the roads will permit. All the lessees are waiting for better roads, in order to ship ore. It is believed that there will be much activity in all lines of mining through the county this season; the town is full of people, it is hard to get a bed, and there is always a surplus of labor here, which is hard to account for, as they can secure work elsewhere.

Ely, February 24.

(Special Correspondence.)—The output of the leaching-plant of the Nevada Douglas Co. is increasing, and soon it will be handling 250 to 300 tons of ore daily, and later 500 tons per day, including a large quantity of custom ore. In January the company sent out 45 cars of selected ore, averaging around \$2000 per carload. Arrangements are being completed for shipment of ore from the Ludwig mine to the Thompson smelter. That smelter is treating 750 tons of ore daily, most of it ore from the Mason Valley and Bluestone mines. It is said that the second unit will be blown-in soon. At present the company is refusing custom ore, but is expected to accept gold,

silver, and lead from nearby properties within 90 days. There are 150 men on the pay-roll.

The Copper Mountain group, under bond and option to the Jumbo Extension Co. of Goldfield, has been equipped with a hoist and compressor and machine-drills will be in operation within two weeks. The shaft has been sunk 30 ft. by hand-work and will be continued to a depth of several hundred feet if conditions remain encouraging. Several sets of lessees are mining and shipping good ore. The Pack Saddle Co. is preparing for shipments of gold ore from its mine in the Reservation district. The new ledge has been driven on for 30 ft. and is 5 ft. wide. Assays range from \$30 to \$50 per ton. Two rich streaks are accompanied by three feet of decomposed quartz.

Two feet of ore assaying \$30 to \$40 per ton has been discovered near the surface in the Reservation Hill mine. The value is largely in silver and lead. It is planned to put in a small pump, unwater the shaft, and resume sinking.

Yerington, February 26.

(Special Correspondence.)—Plans are nearly completed for the building of a railroad from Twin Falls, Idaho, to Jarbidge, and work will probably start as soon as the snow melts. The Oregon Short Line Co. has donated \$5000 toward financing the enterprise, and an additional \$3000 will be paid upon commencement of construction. Several local mining companies have agreed to contribute. The route has been surveyed through a mountainous country rendering road building difficult. There is 12 ft. of snow in the district.

The Elkora Mining Co. has reached the main orebody of the Long Hike mine in the lower workings, and a wide body of excellent ore is showing. It is estimated by the engineers that gold ore worth upward of \$3,000,000 is exposed on the main levels, and plans for a mill will be made. Power will be generated by a plant located on the Jarbidge river. The Elkora company is composed largely of San Francisco people.

Jarbidge, February 28.

(Special Correspondence.)—The old Adelaide mine, 12 miles south of Golconda, is again a producer. Recently a four-inch air-lift was installed and the work of unwatering the main workings was begun. This lift is accomplishing its purpose at the rate of 300 gallons per minute. As the water receded from the upper workings, cross-cutting was begun. This has opened 18 ft. of ore that averages better than 7% copper. This property is under option to the John G. Kirchen interests and under the supervision of W. L. Taylor. Ore is going on the market as fast as teams can be had to transport it to the railroad.

Golconda, March 1.

Excavation is in progress for a 100-ton cyanide mill on the Great Western mine, the property of the Silver Mines Corporation at Hornsilver. It is expected that the mill will be ready by June. Hornsilver is 28 miles south of Goldfield. The ore has been successfully treated by cyanidation at Millers where 4000 tons was sent last year; it runs from \$18 to \$60 per ton. An 8-mile pipe-line for water is being laid.

The Goldfield Consolidated mine is being operated by 12 sets of lessees, and the company is re-modeling the flotation-plant, and expects to resume ore-treatment in a few days.

At the Cracker Jack mine a centrifugal-pump is to be utilized to handle the water, lifting it from the 320-ft. level. The inflow of water has increased lately, but the new pump, which has a capacity to lift 300,000 gallons daily, will take care of all the water that is likely to be developed for some time.

The Florence mine is being put in condition to grant leases, for which there have been numerous applications.

The *Tonopah Miner* reports for the week ended February 24 that the Tonopah Belmont sent to the mill 2906 tons, the Tonopah Mining 3000 tons, the Tonopah Extension 2380 tons, the Jim Butler 800 tons, the West End 648 tons, the Rescue 191 tons, the Halifax 210 tons, the Montana 100 tons, the Mid-

way 57 tons, and the Cash Boy 20 tons, making the total production for the week 10,312 tons, the estimated value being \$185,616. This valuation is calculated on the gross milling value of the ore.

UTAH

The Montana-Bingham tunnel is in 6000 ft. and has passed through several of the properties of Bingham. It has reached the Keystone Extension Mining Co.'s ground. The miners have cut 4½ ft. of vein matter and ore, showing galena, black oxide of copper, and copper glance. The strike is regarded as important, as it was at a point 1000 ft. on the pitch of the vein, is close to the end-line of the Keystone Extension ground, and when driving and raising are undertaken will afford opportunity for the blocking out of an immense orebody.

A streak of unpromising material found in sinking a winze from the 500-ft. level of the Three Kings property at Park City carries \$1707 gold per ton, according to assays and samples taken last week. The streak is 8 in. wide and was found on the hanging-wall side of the winze at a depth of 160 ft. Several tons of the ore were saved last week, though considerable of the material was thrown over the dump before its value was suspected. On the foot-wall side of the winze is a streak of galena that carries 25.2% lead with 11.8 oz. silver and 60c. gold per ton. The winze is being sunk in a fissure that is 17 ft. wide in the limestone. The objective of the work is the underlying limestone-quartzite contact, where the main deposits of ore are expected to be found. The Three Kings property comprises 157 acres near Park City on the north, and close to the Silver King Coalition and Consolidated properties.

For two weeks the Miller Hill Mining Co., operating in American Fork canyon, has been striving to overcome the flow of gas in the main tunnel, now in about 1300 ft. Much equipment has been installed and, by perseverance and courage, the men working at intervals that usually lasted only a few minutes, the shots were placed and fired. But the flow of gas has increased, rather than diminished, and for three days the miners have been unable to reach the face of the tunnel, in spite of their efforts. Additional ventilation fans will be provided by means of which it is hoped the work can be continued, as it is thought a body of ore is near.

A strike of rich ore was made at the King of the Hills mine in Beaver county last week when a body of red oxide of copper was broken into in the winze at a depth of 250 ft. It is reported that the whole face is in good ore with a streak of high-grade 18 in. wide.

The high lead market has increased the earnings of the Bingham Mines Co. and its subsidiary, Eagle & Blue Bell, which is controlled by Bingham through the stock ownership. As both companies receive the prevailing price for lead the week it is smelted, they are in a position to take advantage of the high prices. In the Eagle & Blue Bell, more good ground is being opened and the prospects of a larger production are favorable.

The Victoria, which was bought by Bingham last year, is developing satisfactorily. When shipments were started from this new property the smelters refused the ore, due to their crowded condition. Shipments of ore lately have been resumed. In December profits from this property totaled \$9800.

According to W. K. Yorston, general manager of the building of the narrow-gauge railroad up Little Cottonwood canyon from Wasatch to the mines at Alta, the road has taken out its first ore from Tanner's Flat and hauled it to the Salt Lake & Alta railroad at Wasatch.

By the time that the snow is off the road will be finished up to the South Hecla and to the Emma Consolidated properties. Track is going in at the rate of 500 ft. per day and this will be kept up until better progress can be made.

With the present equipment the road can handle 500 tons of ore per day. The road is a 36-in. narrow-gauge track, equipped with a Shay engine and dump cars.

WASHINGTON

(Special Correspondence.)—The Electric Point Mining Co. has added to its equipment two 30-hp. Pneumatic Tool Co. compressors. The mine is producing daily over 100 tons of lead carbonate and three tons of galena. The Gladstone Mining Co. has found carbonate ore on the 200-ft. level.

Cummins, February 20.

CHEWELAH. During 1916 the United Copper Mining Co. produced 1,179,178 lb. of copper and 159,271 oz. of silver, giving a profit of \$121,581. Monthly dividends of 1%, or \$10,000, are being paid. On the 1000-ft. level the ore-shoot is from 18 to 36 in. wide for 250 ft. length, rich in copper and silver. The mill was re-modeled to good advantage. Concentrate contains 15% copper and 60 oz. silver per ton.

CANADA

The old Vipond mill at Porcupine, now operated by the Porcupine V. N. T. company (a consolidation of the Vipond and North Thompson) has been milling approximately 100 tons daily, from which the bullion yield has been \$8.50 per ton. The assay of Vipond ore has been assumed to average \$8 to \$9 gross per ton, so that the actual recovery of \$8.50 per ton indicates a better return than assumed from average ore.

The gold excitement at Elk Lake shows no signs of diminishing. About 300 claims have been staked.

There is the usual proportion of snow-staking, but there are many properties that show gold and when spring opens there will be many more. The ground has been known for years by the Elk Lake prospectors as one of the best looking formations in the mining country and development work on a small scale has been done at several different points, but it seemed to be impossible to interest capital, and big low-grade gold mines cannot be developed without money and lots of it.

During the month of January the Nipissing mined ore of an estimated value of \$173,988, and made shipments from Nipissing and custom ores of an estimated net value of \$301,692, according to the monthly report of R. B. Watson. The production was below normal during January, on account of the usual shut-down at both mills for the purpose of making the annual clean-up changes and repairs in the equipment.

In the 73-shaft workings, development of vein 400 was continued by sinking two winzes below the fifth level. The south winze reached a depth of 41 ft. and was then stopped, as the Keewatin formation had been reached. The ore continued down to the Keewatin, but was low grade below a depth of 21 ft. The north winze had reached a depth of 10 ft. on the first of February. The ore was of good width, averaging 6 in. wide and from 1000 to 2000 oz. per ton. Several cross-cuts have been run from the fifth level in the hope of picking up parallel veins, but nothing so far has been developed outside of the main vein.

MEXICO

In connection with preparations by the American Smelting & Refining Co. for re-opening its smelter at Monterrey, it is stated that arrangements for operation of this plant have been made between the company and the Carranza government. A special train is to be run from Laredo, Texas, in a few days to Monterrey, carrying a number of Americans to be employed in the plant. The smelter is said to have large quantities of coke, and the company plans to operate its own trains for taking in supplies and bringing out products, as well as transporting ore to plant from the mines. The ore will be obtained mainly from Cerralvo, Matehuala, and Monclova. Advices have been received that the San Toy, Chihuahua, and Santo Domingo mining companies have resumed operations in Santa Eulalia district near Chihuahua. These three companies are employing 1500 men.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

WALTER HARVEY WEED is at Phoenix.

OTTO SUSSMAN is about to go to Chile.

HOWARD D. SMITH has returned from Missouri.

JAMES MURRAY, of Butte, has been taking a holiday in California.

A. B. W. HODGES came to San Francisco from Los Angeles for a few days.

THOMAS B. STEARNS was in San Francisco for a couple of days last week.

CARLOS W. VAN LAW, now residing at Boston, was in San Francisco last week.

WILL C. HIGGINS, editor of the *Salt Lake Mining Review* has been visiting California.

FRANK OLDFIELD has arrived in San Francisco from Jalisco, Mexico, on a well-earned holiday.

WALTER STRACHE sails from New York for Brazil, March 7, on a three months' professional trip.

J. B. TYRRELL, of Toronto, and J. W. Bell, of Montreal, attended the A. I. M. E. meeting at New York.

MAXWELL C. MILTON, of Tucson, was married on March 6 to Miss Josephine Johnson, at Oakland, California.

F. H. MINARD has been appointed consulting engineer to the Mineral Hill Consolidated Copper Co., at Tucson, Arizona.

E. J. SCHRADER has recovered from the effects of an operation and has resumed charge of the Pittsburg Dolores Mine, at Rockland, Nevada.

RICHARD B. STANFORD has resigned as manager of the Bonanza mine, in Nicaragua, and is at home again at New Orleans.

GEORGE H. HARBORDT has resigned as superintendent of the refinery at smelter No. 2, Monterrey, Mexico, to accept a position as superintendent of the Cerralvo smelter belonging to the Cia. de Minerales y Metales, S. A., in Nuevo Leon.

Obituary

HERMANN A. KELLER was killed by a mine-locomotive at Clifton, Arizona, on February 16. He was a mining engineer widely known and respected.

JOHN ADAMS CHURCH, one of the first graduates of the Columbia School of Mines and a distinguished mining engineer, died in New York on February 12, at the age of 74. He was identified with the early systematic development of the Tombstone mines and took a prominent part in the public discussion of Comstock geology. About 35 years ago he was engaged as advisor to the Chinese government. After that he became established as a consulting engineer in New York. He was a man of the highest character, clear-headed, independent and original in his ideas.

EDWARD DYER PETERS, the author of 'The Principles of Copper Smelting' and professor of non-ferrous metallurgy in Harvard University, died at his home at Boston on February 17, at the age of 67. A native of Dorchester, Mass., he graduated from Freiberg in 1869 and then studied at Harvard, where he received the degree of doctor of medicine in 1877. After a wide experience as a metallurgist in the West, he was engaged to report on the Mount Lyell mine in Tasmania and then acted in an advisory capacity. This and the publication of his first book, 'Modern Copper Smelting,' in 1887, made his reputation. In 1903 he became lecturer on metallurgy at Harvard and in 1904 professor. He proved a splendid teacher and expositor. To his books the technology of copper metallurgy owes a great debt. His death is a great loss to Harvard.

THE METAL MARKET

METAL PRICES

San Francisco, March 6.

Antimony, cents per pound	24
Electrolytic copper, cents per pound.....	36
Pig lead, cents per pound.....	9.50—10.50
Platinum, soft and hard metal, per ounce.....	\$105—111
Quicksilver, per flask of 75 lb.....	\$110—115
Spelter, cents per pound	12
Tin, cents per pound.....	47.50
Zinc-dust, cents per pound	18—20

ORE PRICES

San Francisco, March 6.

Antimony, 50% metal, per unit.....	\$2.00
Chrome, 40% and over, f.o.b. cars California, per ton.....	18.00—20.00
Magnesite, crude, per ton.....	8.00—10.00
Tungsten, 60% WO ₃ per unit.....	18.00—18.50
Manganese, 50% (under 35% metal not desired).....	29.00

Manganese ore, 40 to 45%, sells f.o.b. Chicago at 58c. per unit with a penalty of 50c. per unit for more than 8% silica.

New York, February 28.

Tungsten: A shortage of spot tungsten, especially scheelite, caused the market to strengthen in the past few days, and \$18 per unit has been paid for prompt material. Spot wolframite has been taken at \$16.50 to \$17 per unit. A broker reports that an export enquiry calls for 100 tons is under negotiation, while another foreign enquiry calls for 50 tons.

Molybdenite: No offerings are reported, and the only price that can be given is that at which the last sale was made—\$1.80 per lb. for 90% concentrate. Some new properties in the West are to be worked, according to report, but it will be months before the product is on the market.

EASTERN METAL MARKET

(By wire from New York.)

March 6.—Copper is quiet. Lead, spot 10 to 11c., with market nominal. Spelter is firm and quiet.

COPPER

Prices of electrolytic in New York, in cents per pound.

ALUMINUM

Quotations remain unchanged at 57 to 59c. for No. 1 virgin aluminum, 98 to 99% pure. The market is quiet.

ANTIMONY

Ore from South America is being offered for the first time since the break in prices last year. March shipment is quoted at \$2.30 per unit.

PLATINUM

Price of platinum, New York, is \$105 per ounce for soft metal and \$111 for hard.

Eastern Metal Market

New York, February 27.

The freight situation has cleared up a little, and a continuance in this direction is expected to reduce the excessive premiums which are asked for spot metals, particularly lead and antimony.

Copper is as strong as ever. The Government is asking makers of brass and copper products as to the amount of stock they carry, their capacities, and what they can be depended on to furnish in an emergency.

That zinc is not at a higher price is a puzzle to the trade. It continues quiet.

Some lead is getting through from the middle West, but hardly enough to relieve the shortage. Some consumers are selling from their stock, finding it the easiest way to make a profit.

Tin is higher because of apprehension that deliveries from abroad may be interrupted.

Antimony is a little easier.

COPPER

The market continues very strong, with just enough business to establish a price level, and little more. With nearby metal ranging from 36 to 37c. consumers are not disposed to buy except for absolute needs. In most cases they buy to cover contracts when the latter are booked, although sometimes they do not do this, preferring to take chances on the future. Incidentally, fewer contracts are being booked for munitions material. Spot electrolytic copper is scarcer than ever, and one or two consumers who could not find a source of supply have purchased Lake instead, paying 36.50 to 36.75c. for March and April delivery. March electrolytic ranges from 36 to 36.50c. April has been offered at 35.50c., May at 35c., June at 34.50c., third quarter at 32c., and August and September at 31.50c.

LEAD

The railroad situation is clearing up, and more lead is getting through to the seaboard, but not enough greatly to relieve the situation. March shipment from the West is quoted at 9.25c., New York, and April at 9c., whereas spot is quoted at 10.25 to 10.75c. Consumers are not eager to buy at the latter prices, for they realize that they are based on abnormal transportation difficulties. Some members of the trade predict a big slump when the lead in transit begins to arrive in considerable quantities, and they say the drop will be made doubly worse because easier freight conditions will mean that ore will be rendered more plentiful also. Under the circumstances the bulk of buyers have been unwilling to buy for April, or beyond.

TIN

While not a single ship bearing tin has so far been lost as a result of Germany's present submarine warfare (one was lost several months ago) the trade, and consumers are beginning to become alarmed over the aggregate tonnage of ships sent to the bottom. They realize that the situation is becoming more acute. For this reason the market has stiffened in the past week, and Straits tin has again exceeded 50c., the quotation yesterday being 50.50c., against 48.75c., a week previous. The situation is causing more consumers who heretofore have used Straits tin only, to turn to Banca, Chinese, Bolivian, and Australian tin. On one or two days of the week a fair business was done, but nothing exceptional. It is expected that the February statistics will make another good showing. The arrivals up to February 27, totaled 3655 tons, and there was afloat on that day 3323 tons.

ZINC

Consumers have shown but little interest in the past week, and the market has been almost at a standstill. The quotation

for nearby delivery (not spot) is about 10.50c., New York, and 10.25c., St. Louis. Second quarter is about 9.75c., St. Louis. These prices are a source of great disappointment to the producers, who, like everyone else, are puzzled to know why zinc prices have not maintained a better relation to those for copper. With ore around \$90 a ton, the producers assert that zinc costs 10c. or more per pound, and they see very little profit. They ask: if prices are not high in winter, when will they be high? At present levels they are not inclined to sell future positions, and are taking prompt business sparingly. In the latter part of last week there was fair inquiry, but it has since died out with little accomplished. The London quotation for spot yesterday was £47, unchanged from that of a week previous. The exports, February 1 to 27, totaled 8895 tons. Sheet zinc is unchanged at 21c., f.o.b. mill, carload lots, 8% off for cash.

Current Prices for Chemicals on the Pacific Coast

As prices for chemicals are now fairly stable, we are able to give the following list prepared by Braun-Knecht-Heimann Co., San Francisco.

Prices quoted are for ordinary quantities in packages as specified. For round lots lower prices may be expected, while in smaller quantities advanced prices are ordinarily charged. Prices named are f.o.b. San Francisco and subject to fluctuation. Other conditions govern Mexico and foreign business.

Book Reviews

THE PRINCIPLES OF RHETORIC. By Adams Sherman Hill. Pp. 430. 12mo. American Book Company. For sale by the MINING AND SCIENTIFIC PRESS. Price, \$1.50.

This book on the art of writing, by the Professor of Rhetoric in Harvard, ought to be better known to mining engineers, for it is a most useful guide to correct expression. "Rhetoric is the art of efficient communication by language," says Mr. Hill. Therefore, he adds, "rhetoric implies the presence, in fact or in imagination, of at least two persons—the speaker or the writer, and the person spoken to or written to." Thus we come to the principal rule in writing: Remember the reader. The first chapter is devoted to 'Good Use.' At once we find that the author has a happy way of illustrating his teaching with plentiful examples, giving point to his remarks. These arouse intelligent interest and afford practical hints to the student. In choosing forms of expression, "the simpler expression is also the shorter," and it is to be preferred. Then come 'Violations of Good Use,' including barbarisms, improprieties, and solecisms. Here the average writer will find much to learn, recognizing many of his own aberrations. Mr. Hill realizes that "though truth is one, the ways of communicating truth are many." So he is not dictatorial. He tells the student that careful writers avoid this or that usage. By attacking undesirable ways of speech in a persuasive manner he is likely to be more convincing than by the mere assertion of authority, for the proper use of words is largely a matter of taste; yet the art of expression is based on scientific principles; there is a mechanics of writing that can be studied to advantage, particularly in technology. Under 'Solecisms,' the student finds good advice concerning 'shall' and 'will,' doubtful plurals, and the split infinitive. The next chapter is 'Choice of Words.' Under this heading he discusses 'clearness,' 'force,' and 'ease.' Again the wealth of illustrative quotations from good authors adds greatly to the interest of the teaching. It is human to err in writing as in other matters, and much may be learned by noting the effect of blunders made by others. It is a cheap kind of experience and may save a man from a more costly kind. Choose words adapted to convey your meaning to persons for whom your writing is intended; use only as many words as are needed to convey your meaning; arrange those words in the order most likely to convey that meaning. To gather words, the student should study the dictionary, preferring a small one that can be picked up easily; also read the great writers; copy fine passages; and practice composition in order to gain a command over words. Swimming cannot be learned on dry land. Practice the literary scales in order to obtain dexterity. Mr. Hill quotes from Quintilian: "It is not enough to use language that *may* be understood, you should use language that *must* be understood." This means the taking of pains. Most of the bad technical writing is due less to ignorance than to simple lack of care. "Many of the principles of selection which [that] apply to clearness apply to force also." This reminds us that Mr. Hill allows euphony to decide between the use of *who* or *which* and the use of *that*. The reviewer has found it helpful in technical writing to sacrifice such euphony to the clearness that can be gained by giving these relative pronouns their special duties. The relative clause introduced by *who* or *which* is supplementary and continuative, whereas the clause introduced by *that* is restrictive and definitive. In the next chapter, entitled 'Number of words,' the student is taught how clearness, force, and ease are rendered possible.

"A sentence should contain every word that helps to communicate thought or feeling with clearness, force, and ease, but not one word more." Some writers treat their sentences

like a stage-coach in which there is said to be room always for one more passenger. The effective use of connectives—like 'though,' 'for,' 'hence,' 'indeed'—serves to link ideas into a consistent whole. As Coleridge said, such connectives are "the hooks and eyes of the memory." "To multiply words without cause is to be tedious." The smoke hides the fire. "Clearness requires that the words and the groups of words which are near to one another in thought shall be near in expression, and that those which are separate in thought shall be separate in expression." This is a rule that will help the writer out of much obscurity. Of the four kinds of composition recognized by Mr. Hill, two may be supposed to include technical writing: description and exposition. These two are alike in aiming to convey information. "The paramount quality in all such writing should be clearness." "The difference between judicious and injudicious repetition is not so much in the amount of repetition as in the selection of the place for it." "Good arrangement is at least one-half of sound exposition. Order is often equivalent to explanation." "In every case, an exposition should be adapted to the probable hearer or reader." So we come again to the first rule of effective writing, technical or otherwise: Remember the reader. We must leave the subject here. We commend Mr. Hill's book to the young mining engineer as one that may guide him safely in the attempt to write seriously and as one to stimulate him to the attainment of a pleasant style. The book is full of lucid definitions, high scholarship and good sense being united to skilful presentation. As already mentioned, the reader is given a large number of interesting examples—indeed the longer quotations constitute remarkable examples of the best literary styles. The reviewer has found the book useful, therefore he commends it to his fellow-students.—T. A. R.

Kerosene-Engines

The Witte Engine Works has recently made large extensions to its plant to take care of the increasing demand for kerosene-engines. This type of engine has gained in favor through the comparatively low fuel-costs and power efficiency. The engine has been improved and perfected by the Witte company and several new types developed to meet various power requirements. These engines are lower in price than gasoline-engines, which also are made by the Witte company, and are sold on a 5-year guarantee covering fuel consumption. Some interesting figures have been compiled by the company showing the relative efficiency of this type of engine and fuel and engines of other types that will be sent upon request by addressing Witte Engine Works, 3890 Oakland avenue, Kansas City, Missouri.

EDITORIAL

T. A. RICKARD, Editor

OCEAN transport is now so restricted and expensive that the Selby smelter is sending its lead from San Francisco to New York by railroad.

LEACHING of low-grade oxidized copper ores is opening the way for utilizing the waste sulphur-fume from Western smelters. A recent instance is afforded by the Calumet & Arizona, which company will this month bring into operation a sulphuric-acid plant at Douglas, Arizona, making acid for leaching the ore at Ajo.

CYANIDE is selling locally for 95 cents per pound and there is a tendency for the price to drop. Most of the cyanide sold here recently has come from Japan. One Mexican mine obtained 50 tons, for example, from this source. It appears that the British authorities allowed a supply of cyanide to go to Japan in the early days of the War and the Japanese are re-selling it now at a big profit.

CARRANZA has elected himself President. The reports are that he voted for himself almost unanimously. It is pleasing to record this modicum of self-restraint. Meanwhile Zapata remains the unconquered champion of the peasantry in the South, Villa menaces the security of the Carranza dictatorship in the North, and the constitution in defence of which Carranza unfurled his banner has been torn to shreds. Alas, poor Mexico!

RICHARD P. ROTHWELL, if he were alive today, would be astonished to find the technical journal that he established now one of an agglomeration of 10 papers under a single control. The passing of the *Engineering and Mining Journal*, with the other four publications controlled until his death a year ago by John A. Hill, to the group of trade journals owned by the McGraw Publishing Company is an event of some interest. Mr. James H. McGraw threatens to become the Hearst or Northcliffe of trade-paperdom, but, we are glad to add, he has a sense of decency foreign to Mr. Hearst and a scrupulousness disdained by Lord Northcliffe. If the technical-trade press is to be dominated by one man, it is fortunate that he is a man of such high character as Mr. McGraw.

WILL IRWIN in the *Saturday Evening Post*, referring to the American engineer who blew the top off the Col de Lana, on the Italian battle-front, says that he is a graduate of Cornell and has his office in

San Francisco. Just half of this is correct. He is an Italian and he is a graduate of the Columbia School of Mines, and his name is Gelasio Caetani—and he is now in Macedonia, where he carries with him the best wishes of many American engineers. By the way, his cousin, Lionel Lindsay, a graduate of the Mining School in the University of California, and sometime assistant-editor in this office, has been promoted to major and awarded the Military Cross for conspicuous bravery while serving with the British army in France.

VARIOUS announcements have been made by the Mexican government concerning the working of mines; they are changed so often and they come so fast that they are difficult to follow. Therefore an outline of the position as it now exists will be welcome to many of our readers. On September 14, 1916, it was decreed that all mines must be in operation within two months. On November 14, this decree was prorogued, that is, the interval mentioned was extended to February 14, 1917. On February 16, 1917, it was announced that (1) such mining companies as had explained to the Secretaria de Fomento why they could not comply with the decree would be given a last extension of time, to be fixed by the Secretaria, taking into consideration the special conditions existing on each mining property; (2) such companies as have not asked for a postponement will be taken over [*intervenidas*] by the Secretaria de Hacienda; meanwhile loss of title may be declared by the Secretaria de Fomento. For this purpose, a list of all the properties so sequestered will be furnished by the department of Hacienda to that of Fomento.

IN the Butte & Superior Mining Company's quarterly report a reference is made to the use of more than 1% of oil on the ore being treated in the flotation mill. It is stated that the entire plant has been running "for considerably more than a month at normal tonnage and using 1% of oil or more, uniformly throughout all flotation operations. The results of this modified practice have been and are satisfactory in all metallurgical respects. The increase in cost of oil-supply is not a serious item when compared to the royalties which the owners of the patents in litigation exact for the use of their process in the treatment of similar ore." To this we may add that the Elm Orlu Mining Company, operating next-door to the Butte & Superior, pays 84 to 88 cents per ton of concentrate to Minerals Separation, the royalty being 2 cents per unit above 8% in a concentrate assaying 50 to 52% zinc. This, on a 2.6:1 ratio of concentration, is

equivalent to about 35 cents per ton of crude ore. Evidently there is a handsome margin for the cost of more oil. The loss of oil is about 13 pounds when using 22 to 23 pounds of it, but it is to be expected that this loss will be decreased as experience is gained in the use of the larger proportion. The Butte & Superior mill is recovering over 90% in a 48% concentrate. Such results are not restricted by the use of a particular kind of oil; on the contrary, any of the oils commonly employed in flotation will serve equally well. Moreover, the use of more than 1% has proved so beneficial in the treatment of certain mill-products in the Chino, Ray, and Utah plants that the management would not return to the smaller proportion heretofore adopted even if the patent embargo were not threatened. Metallurgically, the employment of more than 1% of oil has now been proved so complete a success as to relegate the so-called 'critical' proportion to the limbo of absurdities. The use of 1% or of 0.1% is merely a matter of economy.

DISCUSSION this week begins with an inquiry from Mr. M. G. F. Söhnlein, a metallurgist now resident in Bolivia, to whom we owe an interesting letter appearing in our issue of June 24, 1916. He wants to know how to obtain sulphur from pyrite and we give gladly such information as we have. The question of sampling large masses of low-grade ore, of irregular enrichment, is discussed by our Mr. Storms. He describes two instances in which ordinary sampling by moil was at a discount apparently. We shall revert to the subject at an early date, and meanwhile invite further discussion from engineers, particularly those experienced in the sampling of large mines. Mr. A. W. Allen, whose writings are well known to our readers, and who has recently returned from Uruguay, replies to Mr. Drucker's enquiry concerning the Krupp type of ball-mill. To Mr. J. F. Mitchell-Roberts, a metallurgist associated with Korean mining operations, more particularly the Seoul Mining Company, we owe a note on the action of caustic soda in flotation. He opens up some questions concerning the coagulation of colloids and their de-flocculation that are still in the twilight zone of physical chemistry. We should be glad to hear from Mr. E. E. Free on this problem. The difficulties met by the poor prospector in obtaining correct assays and reliable determination of minerals are not exaggerated by Mr. J. F. Williams, who writes breezily on the subject. In the West determinations of minerals may generally be had without cost by sending samples to the State mining schools. Assays are a different matter. In every district the trustworthy assayers are generally well known. Given equivalent samples no serious discrepancies will be found in the results from different laboratories. The error is apt to be on the side of sampling. Instruction in this art would constitute useful extension work by the mining schools. From a 'Tramp Mill-man,' who has kept an open eye on mining during his useful peregrination, we obtain a suggestive and humorous analysis of the psychologic effect of pitting man against man in rivalry for

special rewards. He is right. Co-operation, not strife for personal preferment, should be sought in organizing a working force in mine or mill. The growing custom at large properties of holding weekly assemblies of employees for discussion of practical problems arising in their work is stimulating and gives the individual an opportunity to indicate his worth. This practice deserves to be more generally followed.

Imports of Australian Zinc

Readers of our Eastern metal-market page will have noticed frequent reference during recent months to a mysterious shadow overhanging the zinc market. Producers have displayed anxiety to sell whenever quotations showed an upward tendency. Early in January offers of the metal were made at figures so low that buyers treated them with suspicion. On January 10 it was stated that a broker offered January delivery at 9.25, February at 9, and March at 8.75c., St. Louis, and more zinc was forthcoming at those prices than was wanted. The next day selling was still more active, causing a decline of $\frac{1}{4}$ c., and the offerings were made openly, by a firm with alleged German affiliations. It was suspected that German interests were seeking to unload at advantageous prices; but the New York brokers were evidently on the wrong scent. A shrewder approximation to the truth was gained in the conclusion of our correspondent from analysis of market conditions, that "Joplin ore—now quoted around \$90 per ton—is not fixing the price of zinc, but zinc is fixing the price of the ore." The virtual retirement from the market of one heavy buyer of ore and concentrate would suffice to bring about the condition existing. It became known at this time that the United States Steel Corporation was seeking zinc material for its smelter at Donora, in Pennsylvania. The building of this battery of furnaces with a total of 9120 retorts was one of the metallurgical surprises of 1915-'16. The plant was more solidly constructed than are zinc furnaces generally: the erection was an example of the celerity characteristic of the housing of 'war-brides.' Ground was broken on October 20, 1915, and the fires were lighted on March 31, 1916. Here was a brand new smelting capacity of 100,000 tons of ore, or nearly 40,000 tons of metal, per annum, suddenly added to the country's zinc-producing equipment. The threat of an invasion of the spelter market by Anaconda, with designs to meet a post-bellum price of 5c. per pound even if electrolytic zinc should then fail to command a premium for purity, had not been taken seriously enough to affect the situation. Butte & Superior was a more disturbing element. The United States Steel has recently been negotiating with that company for zinc concentrate. It may seem like a long haul, but it is no more surprising than the solution ultimately reached for supplying the retorts at Donora. The Butte & Superior, however, was involved in other plans. Originally its output was contracted to the American Metal Company, which is the representative in this country of the Metallgesellschaft

of Frankfort. This contract called for a certain minimum output, and conceded an option on the maximum. Failure to exercise the option set the Butte & Superior free to deal with the United States Steel if it chose, but instead of so doing it is now understood that it has contracted its excess product, amounting to over 100,000 tons annually, to the American Zinc, Lead & Smelting Company, controlled by the same interests as the Butte & Superior. Not only was this concern contemplating expansion of its own, which precluded the sale of concentrate to the United States Steel, but it had taken options on 4300 acres of land in south-eastern Kansas directly north of the Eagle Picher Company's ground in Oklahoma. A subsidiary organized under the name of the Miami Zinc Syndicate has been keeping 15 churn-drills busy testing that field for several months.

No other large tonnage of zinc ore or concentrate being available for the Donora smelter, the unexpected has happened. The United States Steel Products Company, a subsidiary of the Steel Corporation, has been importing large quantities of zinc concentrate from Australia for the past three months. One consignment of over 6000 tons passed through San Francisco last week. At this rate it would appear that practically the total capacity of the smelter can be supplied from that source. The Broken Hill concentrate averages about 47% zinc. Thus the estimated annual output of 40,000 tons of spelter would be slightly exceeded by the average of 6000 tons per month now coming forward. The disturbing factor in the Eastern zinc market is hereby largely explained. Joplin was counting on an expected demand that had been eliminated. No one would have suspected Australia of entering the American field as a competitor of the Mississippi Valley zinc-districts, especially with ocean-freights soaring to such unprecedented heights; but a great corporation can overcome the obstacles that are insuperable to smaller fry. Moreover, the possibilities of reducing the cost of a 3000-mile haul across the continent, after the Union Steamship Company of New Zealand had landed its cargo at San Francisco, might have failed to appeal to those who had not ascertained the open-minded attitude of the Southern Pacific and Western Pacific railways, which were unbound by published tariffs on zinc ores and concentrates. This is an interesting example of the complex circumstances of metal production, enabling material to be diverted far from the course that would seem logical. The fact that the Steel Corporation, through its subsidiary, the American Steel & Wire Company, consumes its own output of spelter, and needs to be free from the dominance of the metal-sellers, explains the first step in the erection of a great zinc smelter. It may even have been erected without certain knowledge of its ultimate persistent source of raw material, as is now indicated. That it required zinc and that it had cheap fuel in unlimited quantity were enough. There are always opportunities to get what one must have; no man or group of men controls the whole of any needed article. The United States Steel Corporation even now may be looking for nearer sources of zinc; but it is most

improbable that a short-term contract for heavy monthly shipments of Australian concentrate to this country would have been made; the indications point toward an important attraction to this country of the industry of smelting and refining the zinc products from Australia, formerly absorbed by the Belgian and German smelters.

The Consulting Engineer

Mining has need of service from many kinds of men. Among them the consulting engineer takes a place peculiarly responsible and calling for the most intense application not only of scientific acumen, but of character. In modern days, when mining enterprise involves the spending of princely sums of money and the direction of whole armies of men, it is to be expected that the technical advisor to the management shall be specially endowed with mental and moral vigor. That will have been made manifest in the several interviews that we have published with men belonging to this branch of the profession. Time was when the manager of the mine and the company's consulting engineer acted toward each other like the typical bishop and the dean, each jealous of the other's prerogatives and keen to detect any trespass on each other's authority. All that is changed; the childish frictions are absorbed in the sense of big work and the need for hearty co-operation. It has been discovered, however, that the essentially critical pose of the consultant must have for its background some measure of previous experience in managing mines. The consulting engineer must graduate from mine management and not from the class-room or from the stope. In reviewing the careers of our leading consulting engineers, we find that they have served this necessary apprenticeship. For instance, in the interview with Mr. Thomas H. Leggett, appearing on another page, it will be noted that he underwent this essential preparation, after a good training at the Columbia School of Mines. He acknowledges the benefit of the grounding in mathematics that he owed to Van Amringe and in doing so he confirms our idea, expressed on another occasion, that the success of the Columbia men of an earlier generation was due largely to the mental discipline of a rigid mathematical training. Like many other capable men, Mr. Leggett did several kinds of work before he found the opportunity to prove his worth; but all of it counted, we may well believe, in the development of the qualities of keen observation, clear thinking, and intellectual honesty that contribute to the making of the real consulting engineer. Life on the frontier, with its stage-coaches and Apaches, is now almost a thing of the past, at least north of the Rio Grande, but south of that boundary there was, 37 years ago as there is today, all the uncertainty of life and property that the most adventurous might wish. Mr. Leggett is one of many that have found Mexico a post-graduate school. Batopilas and Santa Eulalia are still names to conjure with, and the mention of John C. F. Randolph recalls an American engineer that upheld the highest traditions of

the profession. Then came the Rosario, in Honduras, a great mine and a long-lived producer of the precious metals. A 35th anniversary and a 197th dividend prove that some mines last as long as one of the generations of men. Another outstanding engineer crossed Mr. Leggett's trail in the person of Mr. Walter McDermott, formerly identified with Fraser & Chalmers and now associated with honorable and efficient management of large-scale mining affairs in London. At the Darien mine, on the Isthmus, Mr. Leggett had a chance to show his mettle and to get malaria into his system, as later in Honduras. He also demonstrated his resourcefulness under difficult conditions. Then came Bodie and the Standard Consolidated, a mine that has served to train a number of good men, both in mining and metallurgy. Besides Mr. Leggett himself, the Standard served to prepare Charles A. White, Charles W. Merrill, R. Gilman Brown, F. L. Bosqui, Theodore J. Hoover, R. Chester Turner, and E. H. Nutter. The metallurgy at Bodie covered some of the earlier chapters in cyanidation, and the introduction of electric transmission was another event of far-reaching consequence. In both these departments Mr. Leggett showed that he possessed a mind hospitable to new ideas and able to form correct technical judgments. Then came a wider and bigger opportunity in South Africa. Of this he made good use, winning a reputation, and taking his place among the leaders of the profession. Experience accumulated in divers regions had given him initiative and knowledge for taking his part in the development of the greatest goldfield as yet uncovered by the miner's pick. He places emphasis on the give and take, the exchange of ideas, and the professional solidarity of the American and British engineers then directing the rapidly growing operations of the Rand. He does not say much about the difference of opinion arising from the Jameson Raid and the Boer War, but we happen to know that Mr. Leggett took the unpopular side, and as a democrat his sympathies were with the Boers in their struggle against big odds. He may have underestimated the force of events, the political necessities that ensued, and the inevitableness of the conflict of ideas in his sympathy for a small people that strove to maintain independence and the right to live in their own way. He stood manfully for his ideal, and for that he was respected by those who disagreed with his inferences. Such courage to think for himself is characteristic, and in the end it evoked more of respect than of antagonism. In him loyalty to ideals went with the other loyalties—to his employer, to his friends, to his home. He has never been afraid to speak out, and he has always been willing to give advice or assistance to any man that asked it of him. His helpfulness to others will be recalled by many that will read these words. The remarks on Rhodesia tell an unpalatable truth. The larger part of Rhodesian mining was always done in London: the dealings in paper have been given a greater importance than the digging of ore, and for that reason Rhodesia stands today as one of the most striking examples of over-capitalization, shady promotion, and un-

scrupulous finance. Mr. Leggett does not say all this, but he shows his dislike of the queer doings that the Boers call 'vernukerij.' Near the end of the interview he gives a bit of useful advice to the younger engineers: not to think so much of an increase of salary as to strive to obtain an increase in experience. After all, the one kind of capital that is indestructible—as long as life lasts, and longer if it goes into print—is a knowledge of men and things. At the beginning of a career it is well for the young man to see and learn as much as he possibly can in order to equip himself for the larger opportunity that comes later, often unexpectedly. Mr. Leggett's modest replies to our catechism show how great is the variety of experience that goes to the making of a thorough equipment for consulting work. We venture to add that his record illustrates the fact that it is well to avoid, if possible, going to malarial regions. A young man does foolishly in selling his birthright, good health, for a mess of pottage—increased pay. Nothing can quite compensate for the joyousness of perfect health. We say that because Mr. Leggett's many friends know that much of his most effective work was done when under the handicap of malarial depression. That he overcame it sufficiently to accomplish so much is a tribute to his strong character and to a courage not simply physical. One who knew him at the Rosario mine tells how he 'caught up' some dangerous ground with the help of natives where experienced miners from Colorado had been afraid to venture. With such personal courage goes the power to lead men and to hold them in loyal service. We know that those that have worked under this engineer have an affectionate respect of which he may never have been aware, until now. Does he remember the burly mine-foreman that he ordered out of his office on account of a failure to show ordinary courtesy, and how the man slunk away cowed by an outburst of righteous anger? Such courage was moral rather than physical. It is the quality that an engineer needs to preserve his intellectual honesty and to give unbiased judgment. That quality Mr. Leggett has exhibited in his appraisal of mines. He realized long ago that mining is a business, and that the object of examining a mine is not to determine the genesis of the ore-deposit nor to fuss over the extraction of the last 3% of the metallic contents of an ore—although he knows full well the proper importance of such correlated matters—but to ascertain whether the mine will be a source of profit to those that exploit it. Of this ultimate purpose of mining he never loses sight. He is able to discard the immaterial and to arrive at the conclusion whether a given mine is, or is not, worth the money asked for it, that is, whether having purchased it at that price, it will yield a sufficient profit in a sufficiently short time. These may be truisms, but they have become so mainly in consequence of the opinions expressed and the work done by such men as the subject of this sketch. In him Columbia finds another distinguished exponent of her fine traditions and the profession an exemplar of the code that becomes the scholar and the gentleman.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Sulphur From Pyrite

The Editor:

Sir—In the December 23 issue of your valued paper I read on page 919 that sulphur production from Mount Lyell pyrite has been proved feasible. I have been very much interested in the possibility of recovering sulphur from pyrite for the reason that at the principal Bolivian silver mines the ores are treated by chloridizing roasting followed by leaching with sodium or calcium hyposulphite, and a large amount of sulphur is used for preparing the precipitant and regenerating the solution. This sulphur is now being imported from Ollagué in northern Chile, and costs as much as \$60 to \$80 per metric ton; besides, it is of rather inferior quality, containing only 75% sulphur. The silver ores are mined from veins that frequently contain considerable proportions of practically barren pyrite, which is separated by hand-sorting and left on the dumps.

If a method could be devised to obtain only half of the sulphur contained in the pyrite, that is, the equivalent of the amount sublimed by heating pyrite in a closed tube, more sulphur could be produced than the quantity that is now consumed, and moreover, there would be no more need to import sodium hyposulphite, since it would be cheaper to make calcium hyposulphite locally. The crucial point is, however, the fuel problem. With coal at \$50 and crude oil at \$75 per metric ton, it is probably cheaper to generate the heat by burning part of the pyrite. The operation could possibly be performed in a multiple-hearth roasting-furnace which has one or more muffled hearths built between the roasting-hearths in the zone of highest temperature.

I wonder if such a process is in use somewhere, or if the work being done at Mount Lyell is along similar lines, and would greatly appreciate some information on the subject.

M. G. F. SÖHNLEIN.

Machacamarca, Bolivia, January 17.

[A small amount of elemental sulphur regularly collects in the cooling-chambers between the pyrite-burners and the Glover tower in sulphuric-acid manufacture. This is noted frequently when the proportion of gangue to the pyrite in the charge increases. Control of the sublimation of sulphur from burning pyrite has proved evasive. Results of the efforts at Mount Lyell are not at hand. A method that suggests itself as applicable under the circumstances present at Machacamarca would be to take advantage of the ready absorption of large quantities of SO_2 in a strong solution of sodium sulphite.

The absorbed SO_2 is combined with barium by causing the sodium bisulphite to act upon BaCO_3 . Carbon dioxide is evolved, and barium sulphite precipitated. The barium sulphite is collected, dried, mixed with a small amount of crushed coal, and heated to redness. By this treatment it is reduced to BaS , which can be leached from the cinder by water. The carbon dioxide from the previous reaction is then passed through the barium-sulphide liquor, regenerating the BaCO_3 , and giving off H_2S . Conducting the latter gas into a tower packed with quartz or other inert material, and meeting SO_2 from the pyrite-burner, the mixed gases then rising through the tower and meeting a downward trickling solution of calcium chloride, the sulphur is precipitated according to the reaction

The CaCl_2 does not enter into the reaction, but appears to be necessary to effect complete precipitation of the sulphur. It may be worth while to suggest that the above process may be started by using common barite in the first instance, reducing it to sulphide by heating with coal, leaching and converting to carbonate with CO_2 generated in any convenient way. While the process is theoretically regenerative there is, of course, a small loss of barium in each cycle, which must be made good.—EDITOR.]

Difficult Mine Sampling

The Editor:

Sir—The sampling of mines is never an easy task, and sometimes it is most difficult to obtain samples that correctly represent the value of the vein at the place the sample is taken. Several years ago I had occasion to examine and sample a mine on Mount Gleason, in Los Angeles county, California. The formation was anorthite, in which the quartz occurred as a series of lenses that succeeded each other both in strike and dip. Between the lenses the walls came together, the course of the vein being indicated by a mere seam. From this veinlet the quartz swelled to a width of 7 ft. The lenses were seldom more than 20 ft. long. An adit had been driven on the vein, and at that level the ore was partly oxidized, and the quartz somewhat corroded, as if by some strong solvent. Pyrite was the only sulphide mineral observed, and this showed the evidence of oxidation, though there was little iron oxide. There were many cavities in the quartz, due partly to corrosion of the silica, and partly to the removal of some of the pyrite by solution. In many of these little holes that honey-combed the rock

there remained some loose granular pyrite, sulphur, and metallic gold. There was also some gold in the solid quartz. The quartz was hard, and when an attempt was made to sample the vein, at once the pyrite, sulphur, and gold fell from any holes that were exposed, thus 'salting' the ore as it was broken down. With the use of either pick or moil the same thing happened, for, if a trench but four inches wide were cut across the ore, gold, pyrite, and sulphur would be jarred loose over a width of a foot or more and fall on the canvas. The only safe thing that could be done was to take a large sample over a width of four feet, and even then it was not really representative, for the same reason as before, though in a less degree. Another instance that came within my personal experience was the sampling of a mine in the Colorado desert, about 20 miles from Yuma. There, also, the quartz was hard, but there were numerous seams of finely crushed material, which carried most of the gold. Only large samples could be depended upon, and these had to be discounted as a factor for safety. To me it seems that the only safe way to determine the number of raisins in this sort of cake is to feed it by the ton to a properly equipped mill.

W. H. STORMS.

Berkeley, February 20.

Wet Crushing in Krupp-Type Ball-Mills

The Editor:

Sir—In reply to A. E. Drucker's enquiry, in your issue of February 10, I would refer him for full details to a short article of mine that appeared in your issue of March 7, 1914. I also submitted further data, which were published in a lengthy paragraph in the issue of April 4, 1914. The latter was illustrated.

After an erecting and operating experience with this type of mill in Mexico I was enthusiastic about the excellent results obtained, and I can only presume that the design has not been imitated to any extent by reason of its somewhat complicated construction. I do not know of any other wet-crushing mill where such ample provision has been made for the immediate discharge of material ground to a definite size; where reduction is accompanied by trommel-classification, and where the oversize is automatically returned to the interior of the mill for further grinding.

My notes give me the following data:

Size of mill	5 ft. diam.
Screening used	20 by 20 mesh
Feed size	1½ in.
Horse-power	20
Capacity, tons per 24 hours.....	60

The extra cost of wear and tear of liners and balls, when comparison was made with the dry-crushing mill, was more than compensated by the increase in tonnage, with practically the same expenditure of power. The duty was maintained on an exceptionally hard rock, carrying an appreciable amount of flint, a fact that will explain the advisability of a comparatively small-sized

feed. The mill operates with least attention on a uniform grade of material, both as regards size and characteristics, and it was found imperatively necessary to keep the water in the cone-discharge at the adjusted level.

A. W. ALLEN.

New York, February 17.

Caustic Soda in Flotation

The Editor:

Sir—In your issue of February 17, Mr. C. S. Parsons discusses the action of caustic soda in flotation. I quite agree with him that the first action of the caustic soda is probably to deflocculate the colloidal slime in the ball-mills immediately the ore and water come together. By the time the pulp arrives in the primary Dorr classifiers there is a distinct evidence of flocculation having taken place, the surface of the overflow closely resembling curdled milk, being made up of slime-flocks. So far as present investigations have gone there appear to be few mineral particles in the colloidal slime in the ore, but without the addition of caustic soda the colloidal slime appears to have a greater affinity for coating the mineral particles than does the eucalyptus oil. As the ore at Tul Mi Chung averages nearly 40% limestone, the use of acid is prohibited.

The addition of caustic soda to the circuit has entirely altered the settling properties of the pulp, the calcitic slime-aggregates or flocks remaining in suspension long after the other solids have settled out. To such an extent has this been the case that whereas in former tests an allowance of six square feet per ton per 24 hours to obtain a clear overflow from a Dorr thickener was sufficient, 36 sq. ft. is necessary after the addition of two pounds of 72% caustic soda per ton of ore, in a pulp having a dilution of three parts water to one part of ore. The above conditions vary slightly with the class of ore being milled.

The Prospector Again

The Editor:

Sir—Having read the several contributions on 'What is the Matter with the Prospector,' I will give my views. I say that nothing is the matter with the prospector, except his head, for still following the game. The trouble lies with capital that seeks to kill the goose that lays the golden eggs. I will give my own experience during the past six years. I am a prospector, not a miner, nor a promoter of stocks or of wild-cat schemes. I have, so I think, several good prospects of vanadium, ozokerite, gold, silver, copper, and tin. My first experience was with a tin prospect, four years ago. I found an 8-in. vein, the finest specimen of zinc ore I ever saw. I sent it to an assayer, and it ran \$75 in copper, lead, gold, and silver. I sent a sample to the smelter, and returns came back about \$26. So I dropped it, and

went to work on a big vein of gold and silver close to this property, and accidentally got an assay of \$2000 per ton from a picked sample. This fall I thought I would need the ground where the zinc ore is, so I made a location, not for the copper or gold in the 8-in. vein, for it would not pay, but to have the ground for a dump and a mill-site—we had mineral in place. A friend in Omaha sent for a sample of this ore, and he was sure it was zinc and as he wanted to get in close to this big strike cheap, he had the sample run. After he learned that we had the ground, he sent the assay to me, showing 37% tin. I sent a sample of my vanadium ore to an assayer, and he gave me \$30 per ton. I sent another sample to the Primos Chemical Co., and they reported testing for vanadium, uranium, molybdenum, and tungsten, but did not find anything of commercial value. So good-bye to that. The ozokerite had too much paraffin, so good-bye again. I took a sample of 50 pounds and pounded it fine. I cut this sample from 14 ft. of ore taken across the face, sent 10 lb. to a smelter and got about \$24; 10 lb. to a big mining company, and got \$20, but the company wanted to send an expert at once to look it over. I quartered down six 8-oz. samples of this same ore, sent one to an assayer at home, got \$4.20; one to another, got \$16; one close to the smelter and got \$12.60—all from the same sample. I sent one to New York and got \$67.20; one to Victor, Colorado, and got \$42.20; and one to a man at Durango, and got \$726. I had this examined by an engineer, and he took 14 samples from the property for his company and the highest assay was \$8, and from that down to 40c. Now, what in hell am I to think? Have I got something, or nothing? I can't buy every tin-horn assayer in this community. I can't pay an engineer for a favorable report, nor can I build a mill and put it to work. Now, a friendly prospector, close to our prospect, struck good ore last year that, according to assays from local assayers, ran from \$70 to \$280. Finally, by scratching and digging, and by taking in a partner and giving him half of it, they got enough grub and sacks together to get out two narrow-gauge cars of ore. A grab-sample from every sack, pulverized and quartered down to a 50-lb. sample, returned an assay of \$80 per ton. They felt fine and made another shipment to the smelter. They got \$17 for one car, and \$27 for the other. Take your medicine. It's hell, but 'Dr. Guggy' says "Take it." Now what are they to do? Give it away after 10 years of hard work? Here, too, we have got to give ours away after five years of work, unless we get some relief from our Government or the State. With all the articles I have read, I have not seen a remedy suggested to put the prospector back to the hills. I will give you my idea. Adopt this proposal from the Colorado Metal Mining Association; that each county having mineral-bearing ground, equip a high-school, so they can test for any mineral. Hire a first-class chemist; put him under a good stiff bond to give nothing but a reliable analysis, and have any ore found in said county assayed free; have the prospector sign a contract to give a stated percentage of the sale, if any be made, and a royalty from the net profits for a

given number of years, according to the amount of revenue obtained from property. Let such laws be put in force and the hills will be so full of prospectors they will be bumping into each other within 30 days. Any man that has the nerve to climb the hills can raise 30 days' bacon and coffee and his Climax; but the finding out what you have after you have found it—that takes the cash. And that's what is putting the prospector out of the game.

J. F. WILLIAMS.

Mancos, Colorado, February 10.

The Bonus System in Milling

The Editor:

Sir—The human side of milling seems to have been neglected in the maze of technical discussion of a constantly changing mill-practice. Are the latest ideas in the flow-sheet, or in the most improved machinery, alone a guarantee of highest efficiency and of successful operation? How many of us have seen a ramshackle old mill doing profitable work, while the management of a new plant, equipped with the latest metallurgical fads, has found difficulty in meeting the pay-roll.

Successful milling is simply the intelligent and efficient utilization of the means at hand to secure the most profitable result attainable; not by this means alone, but in the brains and the hands that apply it, lies the secret of successful operation. Given a mill reasonably suited to the work at hand, the human element becomes the chief problem of the manager.

There are mills where men work simply because they are employed, without initiative, attempting no innovation, having no disposition to change existing methods, as wages have been whittled to the minimum. An incentive to improvement is lacking. The workman does as little as he can and still hold his job. Experience has taught him that if he voluntarily does more, then still more will be expected. His main concern is to avoid the displeasure of his immediate superior. Often he has little knowledge of his duties beyond the daily routine, and he cares even less for results. He is being driven, and under such conditions he soon develops those peculiar traits of character that are commonly attributed to the mule.

In other mills the management is more ambitious and offers some sort of reward for the best individual effort, which invariably results in bitter competition and the arousing of personal jealousy, followed by a resort to unfair practices. How plausible it sounds to reward the best individual effort.

Let me cite an instance that came under my personal observation. A bonus was offered to the mill-man showing the highest tonnage crushed, and another to the man that produced the lowest-grade tailing. This looks as though it might have the effect of stimulating the mill-crew. It did. A ball-mill was crushing a soft oxidized ore containing some hard quartz. Under an increased feed—in the effort to secure the bonus for greater capacity—a return oversize accumulated in the mill, and

this, sooner or later, had to be re-ground at intervals, or the feed had to be reduced to the normal capacity of the machine. The day-shift discovered the secret. By skilful manipulation they secured a high tonnage per shift, so gauged as to leave the ball-mill with a heavy load of hard quartz that had accumulated. This it was the duty of the night-shift to re-grind. To do so would necessarily reduce the capacity of the ball-mill and lower the tonnage of their shift, but they met the emergency with a cunning equal to that of their daylight opponents, by substituting a coarser limiting-screen, sluicing the coarse material through the ball-mill into the inadequate classifier, and thence to the cells and tables. This operated to the grief of the man responsible for the tailing on the night-shift, and to the inevitable loss by the company through the disturbed conditions in the flotation-cells, as well as to lower recovery from the coarser pulp. Two hours was often lost before everything could be readjusted for efficient work. Not only was the extraction-man at the mercy of the mill-men, but sometimes he found his froth 'die' suddenly, or start to run, soon after coming on shift; his blower became hot, or his blankets 'dead,' all of which necessitated readjustment, involving the loss of valuable metal, as well as of time and temper.

If a mill-man discovered where an improvement could be made, he kept this knowledge carefully to himself, and applied the idea during his shift, to his own personal advantage in order to win the bonus; and again the company lost through being deprived of the use of the new idea throughout the 16 hours this man was off shift. It was more than hinted that tonnage-samples were increased by the judicious use of a shovel, or by accidentally turning a hose into the sample-bin. When the ore-bin was low, the fine was shoveled forward to the gate, leaving the coarse for the next shift. It was common practice to remove the tailing-sample can from the automatic sampler when starting-up after a shut-down, or, in fact, during the continuance of any unfavorable condition, and under the circumstances these occasions were too frequent. Samples were so cleverly salted against an opposing shift that one man used to cut-down and dry his own samples. He left behind a reputation for making a low tailing.

Thanks to a piece of oily waste, an unfortunate cell-man had his froth die just as a distinguished inventor and metallurgist reached his part of the mill. Of course, the appearance of the waste at this critical moment was scarcely accidental.

The manager of this mill deluded himself into believing that he was securing a high efficiency through the offer of a bonus. In fact, the company was losing many times the amount of the bonus offered through the competitive tricks of men on the various shifts in their censurable efforts to win the reward. Besides, there was created a personal bitterness between the men that was conducive to anything but the best work.

In another mill where the personal bonus system was attempted, it led to such unfriendly rivalry that the samples became absolutely unreliable and the idea was

abandoned. The individual bonus is a step backward and loses all of the advantage that may be derived from co-operative effort. In decided contrast to this is the mill where no individual bonus is paid, and where the mill-crew is working as a harmonious unit. There a spirit of good fellowship prevails, and each man endeavors to leave affairs of his shift in a little better condition than he found them. Any difficulty arising in operation of the mill during a shift is freely discussed with the men just coming on, at the change of shift. Each man employed there is interested in the results obtained by the mill as a whole. There is a constant effort made not to beat the other fellow, but to improve the results of individual work wherever possible. Such self-criticism is the first step toward greater achievement. Each man feels free to make suggestions that he considers helpful, and he thus attempts to satisfy the constructive instinct—a feeling that each man has a part in the work—so necessary to arouse in the men.

It is surprising how men who are apparently hopeless cases will respond and develop under a little personal responsibility, with tactful encouragement. The spirit of helpfulness, and of co-operative effort, is applied to the mill as a whole, and usually with excellent results.

At this last-mentioned mill the superintendent and two of the shift-bosses were formerly employed at the mill where the bonus system had been in vogue. Between men of the same trade there always exists more than a sufficient amount of personal rivalry with its resultant consequences. The problem is how to direct that energy, which may be wasted, into a united effort toward a common goal. Where the best results depend so entirely on effective team-work, as it does in a mill, any proper means that may be introduced to bring about this condition cannot fail to be beneficial. A reward for personal effort is admirable, provided the result, as affecting the whole, is considered. If a bonus is to be paid, it should be divided among all concerned, to the end that the men will strive against themselves as a body, and not against each other as individuals.

TRAMP MILL-MAN.

Nogales, February 4.

THE STEAM-SHOVEL was first applied to mining of copper ore, as far as we know, at the Granby mine in British Columbia, in 1903, a reference to which will be found in the MINING AND SCIENTIFIC PRESS of December 26, 1903, where a shovel was used in an open-cut and later was similarly employed underground. The steam-shovel was used, however, in iron mining in Michigan and Minnesota long before that. The use of steam-shovels in the disseminated copper mines of the West and South-west is an important factor in the economy of their operation.

GOLD to the amount of \$9,000,000 was recently received from Canada at the Philadelphia mint, for the account of J. P. Morgan & Co., bringing total imports from all sources this year up to \$151,000,000, and total imports since January 1, 1915, to \$1,288,500,000.

The History of Flotation

By T. A. Rickard

INTRODUCTION

The various flotation processes depend upon the successful application of a number of physical principles, of which three may be instanced as underlying the methods successively invented.

1. Film-suspension. This is typified by the floating of a needle on water. In the familiar experiment a small needle is greased, either intentionally or by the natural oil on the fingers; but when pains are taken to prevent contact with anything greasy, the needle will still float, if not too large and if carefully manipulated.* If the needle is too large it will not float, no matter how skillfully handled, because the force of gravity overcomes the force of surface-tension, which is the cause of this kind of flotation. Surface tension is the force that causes the surface of a liquid to resist rupture. This, in turn, is due to the fact that the molecules at the surface have a greater coherence than the molecules within the body of the liquid. In consequence, the surface acts as if it were an elastic film.

2. Oil-buoyancy. This is a simple manifestation of gravity, whereby an oil, being lighter than water, will rise to the surface of a pulp and carry with it any mineral particles that have become immersed in it. The oil plays the part of a raft or boat. In order to effect flotation the volume of oil must be such that its smaller specific gravity will overcome the greater specific gravity of the burden it is to bear to the surface. Most oils have a specific gravity of about 0.9, as against the 1 of water; therefore the flotative margin is 10% only. If the specific gravity of a mineral is 5, then the volume of oil required to buoy it must weigh more than 20 times as much. When an ore contains 4% of a mineral having a specific gravity of 5, then more than 1600 pounds of oil will be required to raise the mineral in a ton of ore to the surface of the pulp. It remains to add that oil exhibits a preference for certain kinds of metallic particles, so that it attaches itself readily to them, while passing the particles of gangue. The latter, therefore, are quickly wetted by the water, and sink. The oiling of the metallic particles enables them to resist wetting and lessens their specific gravity so that in the presence of sufficient oil they are enabled to float.

3. Bubble-levitation. This phase of flotation depends upon the aid of bubbles of gas, which, by attaching themselves to particles of mineral buoy them to the surface, like cork-belts or the bladders that children use when learning to swim. Various gases have been tried, but air is now generally used for the making of bubbles.

The attachment of the bubbles to the metallic minerals in preference to the gangue is due to an affinity or selectiveness, like that of the oil, and the presence of oil is said to enhance it. The fact is observed, the theory to explain it is incomplete.

In order that the bubbles generated in, or introduced into, a pulp may perform their metallurgic function they must last long enough to carry their freight not only to the surface but over the edge of the containing vessel. They must not burst untimely. This necessary prolongation of bubble-life is effected by lowering the surface tension of the water, of which their envelope or film is composed. The bursting is due to the contractile force of surface tension, and it must be moderated if the bubble is to last long enough. A decrease of surface tension is produced by putting some impurity or contaminant in the water. Heretofore oil has been the contaminant chosen, as soap is used by a school-boy to blow his bubbles, he having discovered that the bubbles blown in pure water are too fragile for his play. The use of oil was inherited from the prior art, but other re-agents are likely to be found adequate for the purpose.

Thus the third and most successful phase of flotation has grown out of the second, although it is more nearly the logical development of the first phase. Film-suspension involves the aid of air, for the floating of pulverized minerals on the surface of water is helped by the air entrained in the ore. The attempt to invent an effective method out of oil-buoyancy instead of film-suspension goes far to explain the delay that marked the development of this metallurgic process.

EARLY ATTEMPTS

The story¹ of the slow and toilsome development of this metallurgical process may claim to be 'historical' if only for the fact that the use of oil for collecting metals was mentioned by Herodotus. The recovery of gold from the mud of a lake by means of feathers daubed with pitch and held in the hands of apocryphal virgins is as pertinent to the subject as the yarn, 2000 years later, of a young school-teacher in Colorado who was washing oil-stained ore-sacks in her brother's assay-office when she noted that the pyrite floated on the water contaminated by the oil. We know now that the Carrie Everson fabricated in the course of litigation is a myth and

¹This article is intended as a chapter in a book on flotation now being prepared for early publication; the attempt at a historical sketch is published now in the hope that attention will be called to any errors in the story, so that corrections may be made before publication in the book. The author will be sincerely grateful to any reader that will take the trouble to suggest necessary corrections.

*The Flotation Process. See 'Simple Problems in Flotation,' by T. A. Rickard. Page 357.

that, while there was a lady of that name, she was the wife of a Chicago doctor, in collaboration with whom she devised a method based on "the chemical affinity of oils and fatty substances for mineral particles"² and obtained a patent in 1885. She and her husband did ascertain that "acidification of the ore-pulp is necessary for the sharp oil-differentiation of mineral from gangue."³ But the method patented by her in 1885 was a complete failure as a metallurgical process, although it probably did serve to suggest some of the later investigations and it was used freely in the attempt to disprove the originality of subsequent inventions. The odds were greatly against Mrs. Everson: she was a woman, her idea seemed absurd, she had no mechanical ingenuity herself nor was any at her command, and she had no financial backing. If we consider these circumstances, we shall not wonder at her failure to develop a concentration process.

The first patent employing oil for a metallurgical purpose was that obtained by William Haynes in England in 1860. This is of academic interest as being a prelude to flotation. By mixing coal-tar and resin with crushed ore, in the proportion of 5:9, he made a "dough" that held the metallic particles, while the gangue was removed by the help of water and "frictional trituration." The idea proved wholly impracticable and is only worthy of mention as the first recorded use of oil—an oil partly soluble—in the concentration of ores. The next attempt is that of Hezekiah Bradford, an American, who, in 1885, two months before the date of Mrs. Everson's patent, obtained a patent for the first method that was based upon a recognition of the surface-tension of water in contact with air. His method was one for "saving floating materials in ore-separation," such as escaped from arrest by tables, vanners, and jigs. He stated:

"These floating particles appear to possess some peculiar quality which repels the water from their surface, especially when such particles are exposed even momentarily to atmospheric air, and when such exposure takes place the water is repelled from a sufficient portion of their surfaces to cause such particles to float off on the surface of the waste water from the other particles that sink in the water."

He had the germ of an idea pregnant with metallurgic possibility, but it was still-born. Haynes and Bradford had inklings of the physical phenomena underlying the flotation process, but they were pioneers that blazed no trail and crossed no range of fruitful discovery. Carrie J. Everson comes next in point of time. Her groping after a practical process is noteworthy by reason of the introduction of acid, but her trail also stopped at the foot of the talus on the slope of the range. The patent records disclose other abortive attempts in the same direction during the ensuing decade, but none is of any consequence except H. L. Sulman's British patent of 1893, in which he describes a means for saving 'float'

gold by adding something to the mill-water that will diminish its surface-tension. This is interesting as recording scientific curiosity concerning the physics of flotation on the part of a metallurgist that was destined to contribute so greatly to the decisive development of the process. His successful participation is due, in part, to his having been formerly engaged professionally in the chemistry of the oil and soap industries, for thereby he acquired knowledge of a kind that proved of great value to him at a later date.

So far no workable method had been invented—only ingenious schemes and impracticable proposals.

The next incident is this story brings us to the edge of real achievement. In 1894 George Robson, for himself and Samuel Crowder, patented a process for separating sulphides from gangue. He disclaimed "the use of acid or salts and also the method of washing away the gangue with water," and appears therefrom to have been aware of the earlier patents. He effected "the separation of the metallic matter by the mixture of oils alone." Thus he followed in the track of Haynes. The proportion of oil was large: as much as three times the weight of ore. It was a method of buoying the sulphide particles with oil. The process was tried on a working scale at the Glasdir gold mine in Wales and was commended by James Brothers, a firm of experienced metallurgists. But it did not succeed and apparently led nowhere. Yet it opened the way for a decisive event, namely, the technical participation of the Elmore brothers.

ELMORE

Francis Edward Elmore was a trained engineer with an inventive mind. His father, William Elmore, bought the Glasdir mine from Samuel Crowder, in 1896. The conventional concentrating plant, of jigs and shaking tables, had proved unable to make a good recovery of the gold-bearing chalcopyrite in the ore from this Welsh mine. The elder Elmore sent his two sons, Francis Edward and Alexander Stanley, to investigate. It has been stated⁴ by Stanley Elmore that, on the occasion of one of their visits to the mill, his brother Frank noticed copper-pyrite adhering to the oil that had dropped from a shaft-bearing, and thus obtained the idea of his invention: "Finely-divided wet copper-pyrite would adhere to a greasy surface, whereas finely-divided wet rock would not." But no accidental demonstration of the action of oil was necessary to arouse Mr. Elmore's interest in face of the fact that Robson had conducted experiments in oil-flotation on the same spot. We have the testimony of Mr. Crowder himself,⁵ now a very old man, that Robson's experimental oil-concentration plant was on the mine when it was purchased by William Elmore, and we know also, from Mr. Crowder, that he wrote to Stanley Elmore in 1897 urging him to use oil as a means of concentration. In 1898 Frank Elmore obtained his first patent. A working unit of full size was erected at

²As stated by her son. 'Carrie J. Everson and Flotation,' M. & S. P., January 15, 1916.

³H. L. Sulman, Presidential address. Trans. I. M. & M., Vol. XX, page 14.

⁴M. & S. P., September 23, 1916.

⁵M. & S. P., February 24, 1917.

the Glasdir mine. Walter McDermott, Hennen Jennings, and Wernher, Beit & Co. gave the Elmores their financial support and formed a syndicate, which became known as the Ore Concentration Syndicate.⁶

In his patent Frank Elmore describes the process as "Mixing the pulverized ore first with water in considerable quantity, then adding to the mixture an oil of the kind described, which adheres to the metallic constituents but not to the wet rocky constituents." He used a thick oil and introduced the idea of the freely flowing pulp as against the mixing of oil with crushed ore in the presence of only a small proportion of water, as Robson and Crowder had done. By using more water, he also entrained more air, so essential to success, although he did not then recognize this fact. *

In the first plant, at the Glasdir mine, the mixture of crushed ore and water was fed at the upper end of a slowly revolving drum, provided with annular helical ribs and transverse blades, so as to mix the pulp and oil without producing emulsification. The oil was introduced through a separate pipe. The mixture was discharged into a V-shaped vessel, where the water and sand subsided, while the oil buoyed the sulphide particles to the top. An oil-residuum of 0.89 specific gravity was used in equal parts by weight with the ore, ton for ton. The oil was so viscous as to require the aid of small rotary pumps to move it forward. The temperature of the oil and water was kept between 54° and 57° F. The loss of oil was 2 gallons per ton of ore. A concentration of 14:1 was achieved with a recovery (in the concentrate) of 69% of the gold, 65% of the silver, and 70% of the copper from chalcopiritic ore assaying 1.12% copper, 0.049 oz. gold, and 0.8 oz. silver per long ton. These details are taken from a paper by C. M. Rolker read before the Institution of Mining and Metallurgy, on April 25, 1900. Mr. Rolker described the process as "somewhat dirty and nasty," but he stated that "the mechanical contrivances brought into action by the inventor are excellently adapted to the work demanded, and bespeak very careful thought, as well as patient, systematic, and highly intelligent work."

The discussion of Mr. Rolker's paper, as recorded in the Transactions of the Institution, shows clearly that nobody at that time recognized the part played by air in the process of flotation. Stanley Elmore has cited the use of a Gabbett mixer, which causes a violent agitation with indrawing of "large quantities" of air, as proof that he and his brother were "quite cognizant of the fact that it was the air entrapped in the bulk of the oil which rendered it capable of carrying more than its theoretical load of concentrate." But this use of the Gabbett machine was made in 1902, by which time the action of air had begun to be understood. During the discussion of the Rolker paper, two years earlier, nobody present had been able to explain why the actual load of concentrate had been 150% more than was accountable to the dif-

ference in specific gravity between the oil and the water. The manager, John Bevan, had testified that the floatative efficiency of the oil was 25%, against the theoretical load of 10%, on an oil of 0.9 specific gravity; whereupon Frank Elmore remarked: "It seems rather strange that there should be such a difference between theory and practice." On the same occasion Mr. Rolker said: "The viscosity of the oil is the all-important point." Neither H. L. Sulman nor H. F. K. Picard, both of whom took part in the discussion, made the slightest reference to the agency of air, which was entrained with the ore and water while they were being mixed in the revolving drum. As late as January 1903 Stanley Elmore took out a patent for an improved apparatus wherein air was *excluded* from the operation of concentration by oil. But his is not the only attempt to read the past in terms of the present—all the litigants have done it and many of their witnesses. The fact is clear that in 1900 the agency of air was *not* understood by any of the exponents of flotation.

In 1901 the Elmore syndicate established a demonstration plant in London and the free access thereto given to the mining profession, together with the frequent publication of information concerning the process, did a great deal to stimulate interest and curiosity, contributing thus to the later improvements whereby the process was turned inside-out and made supremely valuable to the mining industry. A number of plants were built to apply the bulk-oil process, at mines scattered all over the world, notably the Namaqua, in South Africa, the Le Roi in British Columbia, the Tywarnhaile in Cornwall, and the Sygun in Wales, but it cannot be said that any one of them was an unquestioned metallurgical success.

At this time the treatment of low-grade complex zinc-lead ore at Broken Hill, and more particularly the beneficiation of dumps of similar material discarded in the course of large-scale milling operations, began to stimulate efforts to add some form of flotation to the conventional concentration process. Hence the next chapter of the story concerns itself mainly with the work of a group of Australian metallurgists.

FLotation AT BROKEN HILL

After various attempts at magnetic separation had failed, an effort was made to employ flotation for the purpose of treating the huge accumulations of tailing, which averaged 16 to 20% zinc, 5 to 10% lead, and 5 to 15 oz. silver per ton.

In January 1902 Charles V. Potter, an Australian engineer, obtained a British patent for the flotation of sulphides in a hot acid solution. He used a stirrer and claimed that the solution would "react on the soluble sulphides present to form bubbles of sulphuretted hydrogen on the ore particles and thereby raise them to the surface." Here we have the first suggestion of the bubble idea. In November of the same year Guillaume D. Delprat, manager of the Broken Hill Proprietary mine, applied for a similar patent, except that he used

⁶In 1905 it acquired the Elmore vacuum patents and became the Ore Concentration Company.

⁷M. & S. P., September 23, 1916, page 452.

salt-cake instead of sulphuric acid. In his first American patent, No. 735,071, filed on January 2, 1903, Mr. Delprat states that his process "depends upon the ore particles being attacked by the acid to form a gas. Each ore particle so attacked will have a bubble or bubbles of gas adhering to it, by means of which it will be floated and can be skimmed or floated off the solution." In another place he says specifically: "The sulphides in the ore are rapidly attacked by the acid and gas-bubbles formed on them, that quickly carry them to the surface." In this and in Potter's patent we have the earliest recognition of bubble-levitation. It is true, we have been told⁸ of 'bubbles' being mentioned in connection with an experiment made in 1889 at Baker City, Oregon, where the Everson method was the subject of experiment, but the word was applied to the champagne that was the penalty of a bet, rather than the process itself. A story told in 1915 is apt to read into the happenings of 1889 much that was unknown at the earlier date. Oil and acid were the agents in those futile efforts at flotation made by Thomas F. Criley at Baker City, but it is worthy of mention that the fine grinding of wet ore in the presence of sulphuric acid must have been accompanied by the generation of hydrogen and probably of carbon di-oxide also, if the pulp contained either calcite or metallic carbonates.

Potter and Delprat were mistaken in the reactions that were supposed to follow the introduction of the acid, whether it was the sulphuric, the nitric, or the sodium bi-sulphate that they used variously. At that time it was believed that the sulphuric acid reacted with the sulphides to form hydrogen sulphide without attacking the gangue.⁹ Then it was suggested that carbon di-oxide was generated by decomposition of a carbonate encrustation on the sulphides, due to weathering of the ore, arguing therefrom that it was necessary for the gas to be produced at the surface of the sulphide particles. Such explanations overlooked the simple fact that the Broken Hill ore contains a considerable proportion of carbonates, notably calcite, siderite, and rhodocrosite. From any of these a warm acid solution would release the carbon di-oxide gas that promptly attached itself to the surface of the metallic particles.

The processes of Potter and Delprat have been labeled under 'acid-flotation' and 'surface-tension' methods. In their original form, it is true, they did not include the use of oil, and the apparatus pictured in Delprat's patent (U. S. No. 768,035) suggests the surface-tension method of Bradford, but the use of a baffle "to insure the total immersion of all particles of ore in the fluid or liquor" indicates that surface-tension in its simplest form, as used later by H. E. Wood, for example, was not a principal agent. In Potter's apparatus—a pointed box—the feed has to pass under the surface and is wholly submerged, so that surface-tension again is not given free play, although, of course, it is a factor in the formation

of the bubbles that buoy the sulphides to the surface after the pulverized ore has been mixed thoroughly with the acidulated water.

In August 1904, Auguste J. F. De Bavay patented a process resembling that of Bradford. He used neither acid nor oil, depending entirely upon the effect of surface-tension to form a film of sulphide particles while allowing the particles of gangue to sink. The company formed to exploit his patents claimed that the process worked without either oil or acid, but it was admitted that the flotation was improved thereby, and both oil and acid were used at a later date. In 1910 his rights were transferred to Amalgamated Zinc, Ltd., and in 1912 this company was annexed by Minerals Separation, Ltd. De Bavay's method was employed on a large scale at the North Broken Hill mine and in a plant for treating the dumps of the South and Block 10 mines. It is also used on current zinc-tailing produced at the North and South mines. Treatment is confined mainly to material free from slime. Indeed, none of the earlier processes, the Potter, Delprat, De Bavay, Cattermole, or Elmore did good work on slime—at Broken Hill.

The operation of some of these Australian methods of flotation without oil is an interesting feature. Most of them treated old dumps and it is well to note T. J. Hoover's suggestion¹⁰ that "there may be organic substances in the ore which, upon the addition of acid, yield gummy organic compounds that selectively adhere to the ore." The research of recent years has disclosed the fact that a large variety of soluble frothing agents are effective and that a number of shrubs yield derivatives capable of replacing oil in the flotation-cell.

In 1903 a Potter plant was erected to treat middling from the lead-concentrator on Block 14. Concurrently the Delprat process was adopted by the Broken Hill Proprietary, the plant being increased successively from its original capacity of 3500 tons per week to 5300 tons per diem. Litigation ensued between these two Australian patentees. This ended in a compromise whereby Potter was eliminated; but it is worthy of note that Potter's method was the first flotation process to be used successfully on a working scale.

In 1905 the Zinc Corporation was formed to purchase and treat several large dumps. In 1906 the Potter process was used by this company on the British Broken Hill Proprietary dump, from which a concentrate was obtained containing 44% zinc, 8% lead, and 8 oz. silver, representing a recovery of 81% zinc, 55% lead, and 55% silver, at a cost, including transport, of 50 cents per ton. H. C. Hoover testified in court that the Potter process, as used by the Zinc Corporation, "proved a commercial failure." In 1907 the Minerals Separation process was adopted in a plant erected under the direction of the patentees, but, as Mr. Hoover says, it "also proved a failure, and after exhaustive trials the Elmore flotation process was adopted and found successful." He refers, of course, to the Elmore vacuum process, which was used by the Zinc Corporation chiefly on jig-middling

⁸Ben. S. Revett, M. & S. P., October 16, 1915, page 590.

¹⁰'Concentrating Ores by Flotation.' Page 101.

from the Block 10 mill, until 1910, when, on the advice of his brother, T. J. Hoover, the improved Minerals Separation process was substituted, because it promised to give better results on slime and because the coarse material of the tailing-dumps had been largely exhausted.

As early as 1902, while working with the granulation, or Cattermole, process in the Central mill, the seum of slime made from re-crushed tailing was saved by floating it over a spitz-box. W. Shellshear and F. A. Beauchamp suggested the application of this idea to correct the failure of the granulating process caused by floccules of mineral breaking away from the granules on the tables. The suggestion was put aside until 1903, when a small spitz-box was tried. It was ascertained that the flotation effect was produced while using 9 lb. oil and 22 lb. acid per ton of ore. The proportion of oil was decreased gradually to 2 lb. per ton. This was the real beginning of froth-flotation.

The first mill to use the Sulman & Picard modification of the agitation-froth process, as recorded in U. S. patent 835,120, was the one at the Central mine, built in 1905, as previously mentioned. In 1907 a new mill was finished and by 1908 the recovery had been improved to 85.5% of the zinc, 82.5% of the lead, and 83.8% of the silver, on a material assaying 21.4% zinc, 6% lead, and 8.6 oz. silver per ton, yielding a concentrate assaying 42.5% zinc, 11.4% lead, and 16.6 oz. silver per ton. Concentration was in the ratio of 7:3.

(To be Continued)

The Self-Shooter

Where placer mines lack sufficient water to carry on gravel-washing continuously, either by the sluicing method, or by what is known as ground-sluicing, miners in some localities build what is known as the 'self-shooter,' 'flop-gate,' or 'boomer,' by means of which a small stream of water is made to do efficient service. A dam is constructed across the stream, and a gate is so arranged that, when the reservoir is filled, it automatically opens and discharges. As it rushes out the water is directed by ditch or flume to the working-places, washing the gravel into the sluice-boxes below, which are provided with riffles. The self-shooter, when properly constructed, needs little attention, and the frequency of discharge generally can be regulated to suit the convenience of the miners. The accompanying sketch shows the details of construction of a self-shooter in use near Placerville, El Dorado county, California, designed and built by George Kirchner at his mine. For a description of this we are indebted to Burr Evans. The dam is solidly constructed of a crib of timbers filled with rock and earth, faced with plank and made water-tight. The gate only is shown in the sketch, together with the stationary sill at the bottom, and another timber at the top, the function of which is apparent.

The gate is made of 2-in. planks spiked together, and is provided with a heavy iron plate at the bottom, to overbalance the upper part, as shown. The horizontal

axis of the gate is placed about one-third of the way from the bottom of the gate, and consists of a log of oak or other wood 16 in. diam., hewn to a 10-in. face on one side, and solidly bolted to the planks. The bearings at the ends as shown are turned down in a lathe or shaved by hand, and these rest in boxes of either iron or wood that are bolted to the timbers on each side of the gate and between which it swings. These timbers have been omitted from the sketch in order to avoid confusion. It may be explained that an axis of wood is preferable to one of iron, as when made of metal it has been found to spring at the centre under the pressure of the water, unless very heavy.

When the gate is closed the water accumulates in the reservoir, gradually rising until nearly full. The gate is provided with two latches, as shown in the sketch, these being attached to a frame of scantling. Two air-

THE FLOP-GATE SELF-SHOOTER.

tight cans are also fixed to this frame, as indicated. When the water reaches the level of the cans they lift the float-frame, thus releasing the latches, and the water in the reservoir flows out.

As the axis of the gate is at a distance of one-third its height from the bottom, the greater pressure from the water is obviously on the upper two-thirds of its surface, which causes the gate to overturn, permitting the escape of the water. When the reservoir is nearly empty, the weight of the iron shoe at the bottom of the gate returns this to a vertical position, the latches automatically falling into place and holding the gate closed until the floats again operate. Thus the reservoir re-fills and the gate automatically discharges at approximately regular intervals. Usually two 5-gal. oil cans afford the necessary buoyancy to start the mechanism.

In some self-shooters, a box is placed on the outer side of the dam into which a quantity of water overflows from the reservoir when it has reached a stated height, and the weight of the water in the box is utilized in opening the gate-latches. The principle is the same in either case. All that most miners require is an idea, as usually they have sufficient ingenuity to arrange a contrivance of this kind to suit their own fancy, and adapted to such materials as are at hand.

SPAIN produced 1,464,349 tons of cupriferous pyrite in 1916, from 45 mines.

The Chino Copper Mine

At the Chino mine, at Santa Rita, New Mexico, all of the ore is mined in large terraced open-pits, by means of steam-shovels. Although the ore is not extremely hard it requires to be broken in advance of the steam-shovels. This is accomplished principally by putting down 'blast-holes' of 6 in. diameter, using churn-drilling machines of the Cyclone type, one of which is shown in the accompanying illustration. The machine is driven by a gasoline-engine, and is equipped with traction-gearing so that it is self-contained and can move from place to place as required. Some of the older blast-hole machines are operated by compressed-air, but these are less satisfactory than those run by a gas-engine. The holes range from 25 to 60 ft. deep. The cost of this kind of churn-drilling is stated to be one cent per ton of ore broken. Before a hole is blasted, it is 'sprung' by exploding several small charges of dynamite in the bottom. The hole is chambered four or five times with an increasingly larger amount of powder each time, the first time with 5 sticks, the second with 10 or 11, the third with 20, and the fourth with 28 to 30 sticks. Generally 40% dynamite is used for this purpose. By aid of a hand-mirror the sunlight can be reflected into a hole to a depth of 15 to 30 ft. and the loader can, in this way, often see to a depth varying from 10 to 30 ft. The hole is loaded for the final blast after it has been chambered sufficiently, which depends on the depth of the bore, the hardness, the tenacity, and the volume of rock to be broken. An average charge for a vertical hole on a terrace of ore is: for a 28-ft. hole, 138 lb. of 40% dynamite; 100 lb. Trojan granulated powder (No. 2). For a 50-ft. hole, 170 lb. of 40% dynamite, and 200 lb. of Trojan No. 2. Deeper holes require a still heavier charge. When the ground breaks irregularly on the bottom, horizontal holes are drilled and blasted to secure an approximately level rock-surface upon which the tracks of the steam-shovel may later be laid. When a blast is about to be fired, the alarm is given by the blowing of the whistle on the steam-shovel. The miners in the vicinity take refuge behind a portable steel shield set at a safe distance, so that they may quickly return to work when the danger is past. Large boulders of ore are block-holed, or bulldozed by placing dynamite on the surface of the rock and covering the charge with mud.

There are 14 large shovels in operation, and a dozen or more blast-hole machines are in use constantly, drilling in ore, and in the barren rock that in places covers the orebody. An average of 8500 tons of ore is sent daily to the mill at Hurley, 14 miles distant, where it is crushed and concentrated, the concentrate going to the smelter at El Paso. The cost of producing copper at Chino is about 8.5 cents per pound. The ore is low-grade—about 1.8% copper—but there is estimated to be not less than 90,000,000 tons, as determined by extensive diamond-drilling, and the property is one of the most profitable of the disseminated-copper mines in the country and one of the largest.

Thos. H. Leggett: A Consulting Engineer

An Interview. By T. A. Rickard

You are a New Englander, Mr. Leggett, are you not?

A New Yorker, born at Flushing, Long Island, in 1859.

Therefore, you naturally went to the Columbia School of Mines?

Yes, after going through the introductory and freshman years of the College of the City of New York, I graduated in the class of '79 at Columbia.

What part of your training do you consider has proved of the greatest benefit to you in your work as a mining engineer?

The mathematical course, under Professor Van Amringe, and the chemical course, under Dr. Chandler. It so happened that during my time the mining course was in process of re-organization under Professor Trowbridge, while Professors Hutton and Munroe were just starting as Adjunct-Professors. The summer-school of practical mining, which Professor Munroe inaugurated with the class of '78, was of immense benefit.

What was your first employment?

As rod-man at \$2 per day in river and harbor survey-work under General Newton, famous for clearing the East River of Hell Gate reef by dynamite. It enabled me to get my first experience in coast-surveying and later to take charge of a surveying party.

Where was this?

Along the rivers and harbors round about New York City and its vicinity, Long Island, and New Jersey.

What was your first work in actual mining?

After the surveying in '79 and '80, I was assistant at an iron blast-furnace on the Hudson river, and there obtained my first experience in metallurgy, also in book-keeping, and I am inclined to think the latter did me quite as much good as the metallurgy. When the boom in iron collapsed I was given an engagement in Mexico, on the staff of the Batopilas mines, in the state of Chi-

huahua. These mines were controlled by Alexander R. Shepherd, more familiarly known as 'Boss Shepherd' on account of his political career at Washington, he being the first and last Governor of the District of Columbia. His methods of cleaning up the old town were drastic, but they were most effective, and on his re-visiting Washington in '86 the city showed public appreciation of what he had accomplished.

What route did you take to Chihuahua?

I went through Denver, about Christmas time in '880, and meeting Theodore Schwartz I obtained through him the opportunity of seeing the gold mines of Georgetown and Black Hawk before proceeding to Mexico. I went by train as far as Mesilla, at that time the construction end of the Atchison railroad, and staged 40 miles into El Paso, which town was so crowded that I was thankful for a cot, four in a room, in a little adobe hotel—by courtesy. Then we went by stage to the city of Chihuahua, a six-day trip on account of the snow, thence on mule-back for another six days across the Sierra Madre to Batopilas.

In those days the Indians were still on the war-path?

Victorio and his Apaches were very active, and I remember we sat in the stage-coach with our rifles across our knees most of the way, not that they would have done us much good, but more for the moral effect. I remember the stage being stopped at 10 o'clock one night as we were approaching the end of the day's run, by a Mexican on horseback, who stated that a little way ahead and on the same high-road there had been found the dead body of a Mexican still warm; he wished us to carry the news into the town we were then approaching, and inform the proper authorities by telegram. It was an unpleasant evidence of the nearness of the Apaches.

The Batopilas is a silver district, is it not?

The ore is valuable for its native silver. At that time they were just starting a 15-stamp mill equipped with

Frue vanners, amalgamating pans, and settlers to treat the lower-grade ores that always accompanied the rich native masses though in variable quantity, and carrying pyrite, blende, and galena as accessory minerals. These 'sulphurets,' as they were then called, contained much of the silver of the low-grade ore. The milling process was fully described by John C. F. Randolph, who originally reported on the Batopilas properties, in Vol. X of the Transactions of the American Institute of Mining Engineers. It was upon Randolph's advice that Shepherd and his friends bought these Batopilas mines from a Mr. Robinson, who had worked them Mexican fashion on a small scale for years, and who was then about 70 years of age. It is interesting to note that Robinson moved to Chihuahua and there became interested in opening up the old Santa Eulalia silver-lead mines, which have since become so productive.

How was the silver extracted?

The native silver was extracted by pan-amalgamation, and the concentrate was treated by the hyposulphite leaching process, after roasting. That was the process in vogue all over the West at that time for base silver ores. Walter Brodie was the mining engineer in charge, and he is still consulting engineer for the property, with headquarters in New York.

How long were you there?

Three years, until 1884.

You had a useful experience there?

It was particularly useful as it was my first actual mining experience, and being given charge of subsidiary properties, sometimes at a distance from headquarters, it gave a sense of responsibility and taught one to rely upon his own resources.

Why did you leave?

In order to get wider experience, as the mining at Batopilas was limited entirely to native silver ore of erratic occurrence and requiring but simple treatment.

What was your next appointment?

Chemist to a silver-lead smelter at Lake Valley, New Mexico, but as this plant remained in operation only a few months, I soon returned to New York and took an engagement as mining engineer with the New York & Honduras Rosario Mining Co., in Honduras, where I remained from 1884 to 1887.

This mine is still in operation, is it not?

Yes, and only last year I received a card from the directors commemorating the company's 35th anniversary and its 197th dividend.

This was an interesting enterprise?

Very much so. It was then in the early stages of development; in fact, it was producing only 10 to 12 tons per day when I went there, and inside of two years the output was increased to 100 tons per day of gold-silver ore, an oxidized quartzose ore with occasional cerrusite, pyromorphite, and some blende and galena. On the deeper levels the lode passed out of eruptive rock into the sedimentaries and this was accompanied by a change to

sulphides, and a lower-grade of ore. The development of later years has discovered and opened up a whole series of profitable veins.

What was your metallurgy?

The ore was crushed by stamps and then amalgamated in pans—the original 'Comstock' pan. These, of course, have been superseded now, and most successfully, by the cyanide process.

What was the chief feature of your work at the Rosario mine?

Changing the method of working the mine from a gopher-hole of the Mexican *patio y patilla* type to the systematic operations of scientific mining and the transportation of the ore by means of a steep gravity plane and $1\frac{1}{2}$ miles of Halliday tramway, instead of by mules.

Did the climate affect you unpleasantly?

The climate was, unfortunately, malarial; the altitude at the mill was 3600 ft. above sea-level and the mine nearly 2000 ft. higher, but the foreigners suffered from malaria, and I among them. Indeed, I still have occasional unhappy reminders of my sojourn in Honduras.

So you were not sorry to have a change?

On my return to New York, I found that my friend Walter McDermott had become interested in a mine in Colorado, which experience he has dwelt upon at some length in his paper on 'Salting of Mines,' read at one of the meetings of the Institution of Mining and Metallurgy in London. The ore was supposed to carry native silver in highly payable quantity, but his samples had been salted after his examination, although so careful was he of these samples and so well did he guard them, that it was only through the subornation of an employee of the express company that they were able to get at them. He and his friends had brought suit against the vendors of the mine and he wanted someone to run the 10-stamp mill he had erected on the property, to give definite proof by actual milling operations that the ore was too low-grade to pay; so I operated the mine and mill some six to eight weeks, obtaining sufficient data to fully sustain his contention.

And then?

Soon after I was offered the management of the Darien Gold Mining Company, an Anglo-French concern with headquarters in Manchester, and in the fall of 1888, I left New York to take charge of operations at the mine, which was situated on the Darien peninsula about 150 miles south-east of Panama and about 100 miles inland on a plateau about 2000 ft. above sea-level. A description of the property was published in Vol. XXIX, Trans. A. I. M. E., by a later manager, Ernest R. Woakes. My work was that of the pioneer, having first to build a saw-mill driven by water-power, fell trees, and saw out the lumber with which to build a 10-stamp mill, meanwhile of course developing the mines and installing the water-power plant to run the mill. The surface-work of the Spaniards had taken the form largely of sluicing the decomposed outcrop, or *manta*, and the detritus on the hill-

THE NEW ROSARIO MILL AND CYANIDE ANNEX CLOSE TO THE MINE.

sides, which latter were contoured with the ruins of numberless ditches. Our work was to sink shafts and open up the deposit systematically. The climate was so bad for me that I was unable to remain there long enough to fully develop all the properties. I was succeeded by William H. Radford, and he in turn was followed by

was another well-known Manchester man on the board of directors. After a rest of six months at home I took the management of the Standard Consolidated mine at Bodie, California, subsequently becoming president of the company.

This time you got a high altitude?

About 8000 ft. above sea-level; with a climate described as "nine months winter and three months late in the fall."

What were the chief features of your work at Bodie?

The work there was extremely interesting. The credit for the resuscitation of the old Standard mine is due to Arthur Macy, a graduate of the Columbia School of Mines well known for his record at the famous Silver King mine in Arizona and elsewhere. He first examined the mine in 1890 and on his return to New York, was asked to take charge of the property, which he would not do until the company consented to give him \$50,000 working capital, as the property had been allowed to run down. Macy expended this money chiefly in underground development and had just got the mine into workable shape when he died, so that the most I did was

OLD ROSARIO MILL AND HACIENDA AT SAN JUANCITO, 1½ MILES FROM THE MINE.

Mr. Woakes, who opened up the Espiritu Santo, or south mine, with good results.

You must have been glad to get away.

Yes, the climate was extremely trying, on account of the excessive rainfall in the wet season. By the way, while in charge of this property, I had occasion to go to England to meet the directors, among whom were Lord Charles Beresford and Mr. Hammersley Heenan of Manchester, who was then working very hard to get a bill through Parliament for the construction of the Channel Tunnel between England and France. Jacob Higson

to continue his work. The mine was a system of what an old-fashioned miner would call 'gash-veins,' a network of quartz veins of which many showed no outcrop, while not one in fifty went below the 500-ft. level, but which often were wide, and sometimes rich, at about the 300-ft. level.

Is that the water-level?

No, the water-level was about 800 ft. down the main shaft, which was sunk to 1200 ft., but has not been unwatered for 25 years or more.

How far did oxidation extend?

Down to the lowest level open to inspection, that is, the 750-ft. There were not many veins at this level, indeed, very few of them continued below 500 ft. About four years ago I was asked to go to Bodie, to look into the question of unwatering and re-opening the mines in depth, but I was forced to advise against doing so.

You must have made at Bodie one of the early applications of the cyanide process in California.

Yes, and I found the work extremely interesting. The gulch was full of old tailing, assaying \$5 to \$6 in gold, so one of the first things done was to send a large sample (a ton or two) to the Cyanide Extraction Co. at Denver, the American representatives of the MacArthur-Forrest people of Glasgow.

What year was that?

In 1892. These people advised that the extraction was poor, so the matter of treating the tailing lay dormant for quite a year, until on a trip to San Francisco I met Alexis Janin, who told me of some successful laboratory work he was doing in cyanidation with the assistance of Charles W. Merrill, then recently graduated from the University of California. I immediately sent them some samples of our tailing, and they reported a most hopeful extraction, between 80 and 90%, whereupon I requested Mr. Merrill to come to Bodie, as I felt the necessity of testing upon a larger scale. We used two small tanks, with a capacity of half a ton each, and a small zinc-box about 6 inches square by 8 or 10 ft. long, and we ran 16 charges or 8 tons in all taken from all parts of the tailing-pond, obtaining therefrom a bar of bullion weighing nearly 7 oz., quite large enough to determine definitely whether the laboratory tests would be sustained in practice. The results were so good that we erected the first 100-ton capacity cyanide plant on the Pacific Coast, work being started in June 1894, the plant completed in September, and paid for out of the proceeds by early December, when it was forced to close-down, on account of the severity of the weather. An interesting feature of the little plant was that the tanks were discharged by hydraulicking, using mine-water from a reservoir a few yards up the hill, the discharge-sluiice under the tanks being placed at about 4% grade.

Do you recall any other interesting feature?

Electric transmission of power. We were under the unfortunate necessity of using wood for fuel at both mine and mill, at a price of \$10 per cord. This made very large fuel-bills, and in casting about for a remedy, I found that Mr. Nunn, at Telluride, Colorado, had, in 1892-'93, put in a power transmission about three miles long using the Westinghouse single-phase synchronous system to operate a small mill. Finding water-power 13 miles distant from Bodie, we concluded that if power could be carried three miles it would be fairly safe to try it for 13. On consulting the General Electric Co.'s representatives at San Francisco, I found that the development of power-transmission by electricity was in such an early stage they were still wedded to the direct current, and little as I knew about electricity, I felt the un-

certainty of the methods they proposed. I then consulted W. F. C. Hasson, electrical engineer, graduate of Annapolis, who had just opened an office in San Francisco—in fact, I had the honor of being his first client. This resulted in tying up with the Westinghouse company, which took the contract to carry the power for that distance—13 miles—using a 250-kw. generator at the water-power end, direct-connected with Pelton water-wheels under 300-ft. head, without transformers, the current being generated at 3000 volts and carried on No. 1 bare copper wire to Bodie, where it was applied to the operation of the mill. The plant was in operation in the summer of 1894, but was not accepted until late in that year, on account of difficulties in protecting both the generator and the motor, more particularly the latter, from lightning and from static electricity, with which the air at that altitude was often highly charged. The first lightning-arrestor was of the Wurcz spool type, then just introduced, but it had to be supplemented with other arrestors, and as the company was obliged to give us a 30-days continuous run before acceptance of the plant, I remember it was some months before this was accomplished, although we were really in successful operation of the mill by electric power and the steam-engine and boilers had been disconnected most all of the summer of 1894.

Have you any further metallurgical reminiscence?

Another interesting experience was in connection with the treatment of the concentrate from the 20-stamp mill, which I found equipped with Frue vanners and the Boss continuous pan process, which latter proved ineffective. For the treatment of this concentrate, a drying-furnace had been built of the reverberatory type, and a magnetic separator installed with the object, as was said, of taking out the excess of iron oxide. These, however, had not been used much and there was therefore a large accumulation of concentrate, which had not been shipped on account of the heavy freight and smelter charges, Bodie being 40 miles from the railroad. We tried at once to treat this concentrate, using ton-charges in one of the Comstock pans, with a very heavy addition of salt and sulphate of copper, knowing that a base bullion would result, but there was nothing in the concentrate itself to interfere with the well-known reactions of the *patio* process. The result was most satisfactory, giving quite 85% extraction on a concentrate running from \$120 to \$160 per ton, so that we had a handsome clean-up and the tailing, of course, was all saved and subsequently treated by cyanidation.

How long were you at Bodie?

Four years. I went from there to Johannesburg, South Africa, by way of London, having been retained by the firm of S. Neumann & Co., as their consulting engineer. This was in 1895.

This firm controls several mines on the Rand, I believe?

At that time, while they had large interests, they had not the control and operation of many mines, but this situation changed in a short time, so that they became

THE STANDARD CONSOLIDATED POWER-HOUSE, IN 1894, THE FIRST LONG-DISTANCE ELECTRIC-TRANSMISSION POWER-PLANT IN THE UNITED STATES.

responsible for the operation of such properties as the Consolidated Main Reef, Wolhuter, Witwatersrand Deep, Knight Central, Vogelstruis Deep, Treasury, Cloverfield Deep, and others.

What seems to you now to have been the striking feature of work on the Rand, as you saw it?

Perhaps the most striking feature was the courageous development of the deep-level area, resulting from merited confidence in the persistence of the ore, and the bold manner in which millions were expended on single properties in the systematic effort to reach and open up this deep ground.

You liked the mining laws of the Transvaal?

Yes, indeed; a striking feature of the mining was the absence of litigation. The Witwatersrand mining area comprises a stretch of country now about 50 miles long by 2 to 3 miles wide, covered from end to end with min-

ing claims grouped into mining companies in active operation and often controlled by men of different nationalities, yet a mining law-suit is a practically unheard of thing, while those that have occurred during the past 20 years can be counted on the fingers of one hand. This is eloquent testimony to the practical efficiency of a mining law that limits the four sides of a mining claim by vertical planes.

Were you interested in the geologic study of the Rand?

The geological work on the Rand was highly interesting, and we were visited by many eminent and distinguished geologists, among whom were Agassiz, de Launay, the French authority, and Becker of the U. S. Geological Survey. Dr. Becker was one of the first of these geologists to visit the goldfield, coming there early in 1896, and he did some really remarkable work, with which I had the privilege of keeping in close touch, as he

THE CONSOLIDATED MAIN REEF MINE

was engaged by my firm. One of his chief investigations was a search for the westward continuation of the main Reef series, on which he spent several months with the result of establishing the existence of an extensive fault, beyond which that lode series was lost. He constructed a model to illustrate the existing condition and so far as I am aware his findings have never been disputed, nor the continuation of the Main Reef series found.

Another happy feature of our work there was the lack of secrecy; the readiness with which the underground workings, the surface equipment, the assay-plans, and the milling results were thrown open to the inspection of visiting engineers—the good fellowship that obtained among them and the entire lack of professional jealousy. Many problems had to be solved in those days—mining, mechanical, and metallurgical—and the exchange of ideas among the engineers and metallurgists that had to attack them was cordial and unrestricted.

What did you think of British company methods?

The English methods of company administration, with their reports conspicuous for their thoroughness and their close attention to detail, were something of a lesson to the American mining engineer. The American, always keen for results, was in those days given perhaps to taking too many short-cuts with a possible slurring of apparently unimportant administrative details. The influence of the thorough and methodical methods of the English administration was most salutary. The explicitness of the reports of the Johannesburg mining companies is a case in point. Take for illustration a report just received from one of my old companies for the quarter ending July 31, 1916. Although it has been operating for over 20 years it starts with a statement of its capital thus:

"CAPITAL - - - - - £860,000

"In 860,000 fully paid-up shares of £1 each. (Fully issued.)"

Then "Directorate and names of directors and alternates.

"Head Office - - Cullinan Building, Johannesburg

"London Office - - Salisbury House, London Wall"

Then follows, "Expenditure and Revenue statement" (for the quarter).

"Calculated on the basis of the tonnage milled."

"120 stamps, 4 tube-mills, and cyanide works.

"Milled, 107,000 tons."

Detailed "Working Expenditures and Revenue" given in two columns, one of totals and one of "per ton milled," and final totals of yield, cost, and profit for the three months as follows:

		Per ton
Cost	£95,161	17s.9.45d.
Profit for quarter	40,774	7s.7.45d.
Yield	£135,935	25s.4.90d.

Then follow details regarding the operations for the quarter in mine and mill, with statement of ore-reserves, their estimated value, etc.

Could anything be clearer or more satisfactory to the stockholder? Most if not all of even our best-managed mining companies producing gold, copper, or other metal—companies the excellence of whose management is beyond criticism—while giving in their quarterly reports to stockholders a comprehensive statement of the three

months operations with yields, costs, and profits in detail, make no mention of such important matters as the place of incorporation of the company, amount of its capital, number of shares issued, location of offices, etc., while even in their annual reports one has usually to refer to the accountant's statement to get information stated on the front page of every English report, quarterly or annual.

These important details regarding a company are always of value, but especially so to a stockholder living away from the big centres or in some remote part of the country, and no doubt their incorporation into the reports of our mining companies will soon be adopted in view of the great progress already made in this direction. As regards the unnecessary amount of red-tape with which the English administration of mining companies is often credited, it is only fair to say that the Johannesburg companies were in turn benefited in this respect by their contact with American methods.

Do you, or do you not, believe that the Main Reef series has become impoverished in depth?

It is now ten years since I have been on the Rand, and I have naturally fallen out of touch with the development of the deeper workings, as also with the local economic conditions that are almost as vital as the grade of the ore, but I have obtained the impression that there is a falling off in the grade of the ore, taking the Rand as a whole. There have been notable exceptions to this, more especially on the eastern flank where, in some mines, such as the Brakpan, high values obtain and still exist in large areas and over considerable reef-widths, as much as 4 and 5 ft., but my impression is that these rich areas are more scattered, and that therefore, taking the deep ground as a whole, its gold content will average less per ton than that of a corresponding area closer to the outcrop. This is in accordance with the general experience in gold mining the world over.

Did you have any unpleasant experience at the time of the Jameson Raid or the beginning of the war?

Nothing particularly unpleasant. Those days were often exciting and always interesting. Many of the American mining engineers kept out of the Raid and all but one or two out of the war. Our families went to the Coast—to Durban or to Capetown—three or four times on various war scares, and of course the final exodus just before the war was disagreeable on account of the crowded condition of the trains. On the whole, it was remarkable how slightly the operation of the mines was interfered with, up to the actual outbreak of hostilities.

By the way, when were you married?

I was married in March, 1891, to Miss Fanny Marshall Borrowe, and we have three sons, the eldest about to be graduated with degree of M. D. from the College of Physicians and Surgeons in New York.

Do you consider that the Rand offers a good training in mining?

It undoubtedly does. It affords excellent training in

modern methods of underground work, and of large-scale operations in deep hoisting, pumping, ventilation, etc., at the same time instructing in details with characteristic English thoroughness. Also for learning the particular phase of metallurgy in use there—stamp-milling and cyaniding of quartzose gold-ores—I know of no better field, but, in order to widen the young engineer's experience and knowledge, work there should be followed by work in different types of deposits in other parts of the world.

How does the Kaffir labor compare with the Mexican?

Very favorably. The Kaffir, after a month or two of breaking-in, becomes a fairly good worker. But in order to obtain the best efficiency it is necessary to employ the task system, under supervision, of which the Kaffir re-

of the principal mines, the Globe and Phoenix, Giant, Selukwe, and others, but I left with the impression that the country was plastered six feet deep with mining shares. The Blue Book, issued at that time by the Chartered Company, showed, if I remember rightly, some 250 to 260 companies with capitalizations ranging from £50,000 into the millions, and you could count on the fingers of one hand the number of producing paying mines. Doubtless by now this too has been largely remedied.

What was your next move?

In the autumn of 1903 I returned to London, where I opened an office in Salisbury House for independent mining engineering work, retaining connection with the firm of S. Neumann & Co. I lived at Chislehurst, with

COMMISSIONER STREET, JOHANNESBURG.

quires but little more than the Mexican. Like the Mexican, he is docile, and as he is given no chance to drink while in the compounds, he is always ready for work on Monday morning, whereas the Mexican has his too frequent fiestas.

How about the white labor on the Rand?

In my time the white laborer was highly paid, sometimes to excess, considering the amount of work done. It was necessary, in order to be sure of a full day's work, to put him on contract. This was at a high figure, partly on account of the great demand, so that a good miner would often make as high as \$300 to \$400 per month. All this has been remedied in the past ten years, so I am given to understand.

How long were you in South Africa, Mr. Leppell?

Eight years.

Did you go to Rhodesia?

Yes, I made one trip to Rhodesia, and saw there some

headquarters in London, until 1907, making several trips to the United States in that time, and a couple to Russia and Siberia, including the examination of the Spassky copper mine, which was then in the early stage of its development.

Another interesting examination was that of the Sudbury nickel-copper district in Ontario, with special reference to the Victoria mines of Dr. Ludwig Mond, whose properties were at that time—1901—largely undeveloped, though fairly extensive diamond-drilling had been done. I remember suggesting to Dr. Mond, whose private car was on a side-track at the mine during the examination, that he approach the Canadian Copper Company with a view to buying them out, thereby making a business of sufficient size to be worth his while and at the same time securing going properties. That company was then diamond-drilling its extensive Creighton deposit. Dr. Mond went to Cleveland, Ohio, the headquarters of the Canadian Copper Company, but returned

shortly saying they asked the unwarranted sum of \$6,000,000 and that anyway they would have to come to him sooner or later, as he controlled the only true process of separating nickel and copper. Dr. Mond, in addition to his other famous work in the field of chemistry, discovered and finally put into successful operation a process for making this separation, hence his desire to secure nickel mines and his participation in mining. All the matte from the Victoria mine, after being brought up to about 40% each of copper and nickel, was sent to his works at Clydach, in Wales, for final treatment and separation. But in this case the chemist got the better of the business man, for inside of eighteen months Schwab bought these properties, which are now consolidated into the International Nickel Corporation. The Mond company, however, is also in successful operation at Sudbury.

Have you any opinion as to the prospects for American enterprise in Siberia?

I think it has been largely forestalled by the activity and initiative of the English mining houses, which have had their representatives there for the past ten years. It is true that some of these representatives have been American engineers, but they have mostly been connected with and working for London houses. I think, too, that this is too far afield for American capital, just as South Africa has always been considered to be too distant, quite aside from the fact that in the latter country all the opportunities were already pre-empted.

Then you realize, or you believe, that the American capitalist has not yet learned to use his money far from home?

I would hardly go so far as to make such a statement, in view of the amount of American capital that has been invested in mining on this continent, stretching from Alaska in the north to Chile in the south; I would rather say that American capital in the mining field certainly has been largely restricted to this continent, and apparently with good reason, considering the undeveloped areas that have existed and still exist.

When did you leave London?

In 1907, when I moved to New York, and opened an office in Broad Street, being joined there in 1908 by my friend and former assistant in South Africa, Fred Hellmann. We remained in partnership until the spring of 1912, when I became consulting engineer for the American Smelting & Refining Company and a little later Mr. Hellmann took charge of the Chuquicamata mine for the Chile Copper Company.

Reviewing your career, what piece of advice would you most like to give to the younger men?

I think one of the most important things for the young mining engineer to bear in mind, one of the best lines of action he can adopt is to disregard the amount of pay received during the first years after graduation and devote himself to acquiring a wide experience covering as many different types of ore deposits and methods of mining and metallurgy as possible. While thus broad-

ening his experience he will also be enabled to make a wiser decision as to the line of work along which he prefers to specialize. I am also a believer in a young engineer spending a goodly number of years in the actual operation and management of properties, for nothing can replace the executive experience and knowledge of men so gained. If he follows this course the matter of emolument will soon regulate itself to his satisfaction.

Are any of your sons to become mining engineers?

My eldest son receives his degree of M.D. next month. My second son, now Second Captain of the Battalion and in his last year at the Virginia Military Institute, is thinking strongly of electrical engineering as his life work, while my youngest son is only 14, and we don't know yet what he will be, but there is always a possibility of his wanting to become a mining engineer.

Do you consider that smelter settlements should be based on the price of metals, as quoted in a trade paper? Do you think it advisable and practicable to take the prices at which the smelting company actually sells the metal, and use that as a basis of settlement, making a temporary adjustment until that price is ascertained?

I think it most advisable that settlements between smelteries and their customers should be based on the actual price obtained for the metal sold by the former and not upon a trade-paper quotation, but I question whether it is practicable to do this. "It is a condition and not a theory that confronts us," and as the metals are sold chiefly by agents or selling companies acting on behalf of the smelteries I doubt very much whether it would be possible to get them to disclose in each instance the actual price obtained, especially since they frequently have to carry over the metals for some very appreciable length of time.

NEW APPLICATION OF CYANAMID TO PHOSPHATE ROCK. Extensive and completely equipped phosphate properties in the pebble-rock district of Florida have been purchased by the American Cyanamid Co. of New York, comprising the mines of the Amalgamated Phosphate Co. at Brewster, Polk county, in the centre of the pebble district, and the output will be used for manufacturing a new fertilizer, containing ammonia and phosphoric acid, which the American corporation will manufacture in the plant it has recently completed on New York harbor. The phosphoric acid will be derived from the Florida phosphate rock and the ammonia content from the cyanamid which the company manufactures at Niagara Falls, Ontario. The entire present output of the phosphate mines having already been sold for a period of years, the American Cyanamid Co. is installing equipment to double the output. The mine will be operating at its enlarged capacity by the end of this year. Increasing demands for cyanamid products will cause the American corporation to increase its holdings and add to the activities of rock-phosphate mining. The mining of phosphate rock in the United States began in South Carolina in 1867.

The Miami Appeal—III

We quote further from the Minerals Separation oral argument. Mr. Kenyon is insisting before the Court that 835,120 is a pioneer invention.

Now, the essential things in our process are the air bubbles in a modified pulp and collision of those air bubbles with the metal particles, and all else follows from that.

Just those three things: Air bubbles, a modified pulp, and sufficient movement to bring about the collision of those air bubbles and the metal particles. Whence or how the air bubbles come is a non-essential. They are not altered by the way in which they come. It is the same air. It has the same characteristic imparted to it by the modified water which appears when it comes out as a bubble. How the collision is brought about is a non-essential.

Another way of putting it: Whether you aerate by agitating—I would very much like your Honor's attention. I am coming to that afterward, if you will excuse me, as my time is so short. Now, whether you aerate by agitating, as here (indicating the Gabbett cone mixer) or agitate by aerating, as here (indicating the defendant's Callow cell)—whether you aerate by agitating as in our first example in our first patent in suit, or agitate by aerating as in the second example of our patent, you have in both cases these five things: (1) Critical proportions of oil present; (2) the peculiar air bubbles incident thereto; (3) the contact of these bubbles with the metal particles; (4) flotation by reason of that contact; and (5) froth-formation above the pulp carrying those metal particles.

And the peculiar air bubble function in essentially the same way as described in the patent in suit (page 1. lines 89-96). They take hold upon the metal particles with which they collide, and never thereafter let them go.

THE COURT (Buffington, C. J.): And so permanent in the defendant's machine—

MR. KENYON: Yes.

THE COURT (Buffington, C. J.): That they last for twenty-four hours. I say, in the defendant's machine.

MR. KENYON: Yes.

THE COURT (Buffington, C. J.): That they last for twenty-four hours. That is what the Supreme Court said.

MR. KENYON: Won't you just let your mind remain open on that?

THE COURT (Buffington, C. J.): I am only calling your attention to the fact that in connection with that argument I was following here what the Supreme Court had said.

MR. KENYON: I am going to apply my argument to what the Supreme Court says.

The air bubbles function in essentially the same way.

however you get them in—that is determined by the modifying agent in the water—and the two means or ways of getting them in and of bringing about the collisions are mechanical equivalents for one another in the prior art, and well known mechanical equivalents, as I have shown, and they produce the same concentration of ore result, and through and by means of substantially the same froth carrier, a froth carrier that has the two characteristics that the Supreme Court emphasizes, namely, (1) minuteness of oil, and (2) large percentage of the ore metal, and that is persistent and coherent enough to do the work that it is called upon to do by the process.

THE COURT (Buffington, C. J.): Mr. Kenyon, where do you get the air bubbles in this beater process of yours? Where do you get them?

MR. KENYON: Well, your Honor's mind has to be disabused of that notion that there is any beater in our process. Our patent does not show a beater.

THE COURT (Buffington, C. J.): Well, you certainly describe a beater.

MR. KENYON: Not in our first patent. We did that in our second patent.

THE COURT (Buffington, C. J.): The Supreme Court thought you had a beater, didn't it?

MR. KENYON: Now, you force me to come to that.

THE COURT (Buffington, C. J.): No; I do not force you to anything.

MR. KENYON: I am only going to ask you to underline two phrases in this opinion of the Supreme Court that may have escaped your attention.

On page 3 of this little pamphlet, the second paragraph, please underline these words:

"The process of the patent in suit *as described and practised.*"

Now, everything that follows that is simply practice, description and practice.

Now, in contrast to that, will you turn to the last page of this opinion? I hope it will be illuminative. The last page, third line:

"And the patent *must be confined.*"

Now, there is the only construction of the patent as a monopoly in that whole opinion. "And the patent must be confined." All that preceded it, every word that was said before it was a description of something as practised, as described either by witnesses who were talking about practice, or their actual practice.

Now, I am going to come to that.

So that there is nothing of limitation in that opinion until you come to the last paragraph. There is only description until you come to that last paragraph. And, if your Honors please, in my judgment, for what it may be worth, no nine judges will be more astounded if your Honors should go on record as finding in this decision of

theirs a limitation of this invention to any particular kind of agitation or any particular kind of froth.

Now, may I take up the thread of my argument—

THE COURT (Buffington, C. J.): If that is the case, we have the assurance that if we go wrong we will be instantly corrected.

MR. KENYON: We shall make every effort in the Supreme Court. We have to, of course, because this invention is the most important invention—this group of inventions are the most important inventions—

THE COURT (Buffington, C. J.): Mr. Kenyon, that is why I wanted to get your views on it, and I ask you a plain question. You certainly show a practice.

MR. KENYON: Yes.

THE COURT (Buffington, C. J.): Do you agree with me?

MR. KENYON: We show a practice, surely. But our patent is not necessarily—

THE COURT (Buffington, C. J.): And that practice consisted of what has been called here "beating in air."

MR. KENYON: No. Well, I will come to that.

THE COURT (Buffington, C. J.): Then you didn't show it?

MR. KENYON: We did say that in our second patent, and in our practice about the year 1908, and that is what the Supreme Court was talking about. It was the particular froth, gotten in that practice, applied to a particular ore (that had 45% of metal in it) that all those witnesses were talking about—that the Supreme Court quoted.

Now, just think of that a moment. Forty-five per cent of metal. Pretty nearly every other particle a metal particle. Contrast that with the defendant's ore. One per cent of metal. One particle of metal in every hundred. Ninety-nine collisions are with gangue particles. You must have with the defendant's lean ore a super-abundance of air. At least, one can well appreciate why there should be myriads of air bubbles searching everywhere, through every nook and corner of that ore pulp, so that not a single one of those few and far between metal particles shall escape. And, now, in the other case, when you get a froth in which every bubble carries fifty metal particles (because they will keep on attaching themselves to a bubble until it is absolutely armored) those armored bubbles, even after the water film of the bubbles had dried away, would stand up there as skeleton bubbles. That phenomenon we have seen. Simply because of the richness in metal, and that richness simply because the concentration was of an ore rich in metal.

Now, along that line is the explanation of all this confusion about the early practice of this process.

THE COURT (Buffington, C. J.): I do not seem to be able to get the thing to you, that this is an honest groping in my mind for what I am unsatisfied about.

MR. KENYON: Yes.

THE COURT (Buffington, C. J.): I take it that you cannot have a bubble unless you have got some air inside of it. Am I right?

MR. KENYON: You are right. You cannot have a bubble below the surface without getting in air below the surface.

THE COURT (Buffington, C. J.): Above or below the surface, you cannot have a bubble anywhere, unless you get some air in.

MR. KENYON: Yes. Even with the froth you cannot get a bubble without having some air inside of it.

THE COURT (Buffington, C. J.): Now, you get bubbles. You disclose a way of getting bubbles.

MR. KENYON: No.

THE COURT (Buffington, C. J.): You do not? Then, I am through. Our minds are so far apart that I don't know. Because when the House of Lords, or whoever it was over in England, spoke there of forming a multitude of air-cells, I thought there were air-cells in this thing. But you tell me not.

MR. KENYON: In the pulp? Yes; there are air-cells. I have misunderstood you. What I meant to say was that we did not invent some particular way of getting that air in there.

THE COURT (Buffington, C. J.): I don't care whether you invented it or not. You have said, haven't you—

MR. KENYON: Yes, that is what we invented, getting cells there any way you please, and then movement any way you please.

THE COURT (Buffington, C. J.): Do we start with the proposition that there is air in cells?

MR. KENYON: I don't think you can have a cell without air.

THE COURT (Buffington, C. J.): Do we start with that proposition?

MR. KENYON: I am willing to start there, yes.

THE COURT (Buffington, C. J.): I am not taking a hypothetical case, I am endeavoring to get down to the facts.

MR. KENYON: Yes.

THE COURT (Buffington, C. J.): Do we start with that?

MR. KENYON: Yes.

THE COURT (Buffington, C. J.): If we do not, why say so, and I will know where we are.

MR. KENYON: I do not know where you mean to start. You mean before we start the machine going?

MR. GARRISON: He means you cannot have a cell without air.

THE COURT (Buffington, C. J.): I will not take up your time.

MR. KENYON: You cannot have a cell without air. Can I help you along that line?

THE COURT (Buffington, C. J.): I am afraid I am taking your time.

THE COURT (Woolley, C. J.): If I understand your reference to what the Supreme Court said on page 8, when you asked us to underline the words "the patent must be confined"—that is, must be limited?

MR. KENYON: Yes.

THE COURT (Woolley, C. J.): "To the results ob-

tained by the use of oil within the proportions"—which is one per cent—"often described in the testimony."

MR. KENYON: That is the only limitation.

THE COURT (Woolley, C. J.): Then that means precisely what Claim 12 that was cancelled means, does it not?

MR. KENYON: Oh, no.

THE COURT (Woolley, C. J.): Then clear me up on that. As I read that limitation, if that limitation means, or rather if that language means, that you are confined to the 1%, and confined by nothing else, limited by nothing else, then I think that means the same as your withdrawn Claim 12.

MR. KENYON: The Court was speaking of our claims which were before it and which are here. Those claims specify agitation and froth. When you get those three things together, that minute quantity of oil and agitation and froth, you have—

THE COURT (Woolley, C. J.): That is what the Supreme Court says on another page. You are tying us down to this one sentence on page 8.

MR. KENYON: Only on the matter of construction. They only construe the patent there. They explain the process everywhere up to that point. There they lay down a limitation of the patent and that is the only limitation they lay down.

THE COURT (Woolley, C. J.): Then we are not confined to the use of oil, but we may consider the question of agitation and the result of the oil and agitation in the nature of froth, is that the idea?

MR. KENYON: Yes. It is perfectly open to this Court, in my judgment, to interpret agitation any way it pleases, to interpret froth any way it pleases. I do not think the Supreme Court has passed upon what the limitation of this patent and of this invention as to the agitation is or what the limitation of this patent as to froth is. It has simply passed upon what the limitation of this patent as to the quantity of oil is.

As to froth, the patent in suit contains no requirement—you may read it from end to end—other than that it do the work of carrying the metal up out of the liquid and over. Whether it be more or less aerated is a matter of degree, not a difference of kind. We made our froth here before you and put an excess of air into it. And can you say that the froth was thereby changed in kind? It had the same minimum proportion of oil. It had the same large percentage of metal. It was still capable of carrying the metal and going over a lip, and therefore acting as a separator and conveyor for that metal. All the essentials were there that were required by a froth in this art.

In both cases, aeration by agitation and agitation by aeration, there are present these two things: there is present aeration and there is present agitation, and the co-operation of the bubbles and the metal particles proceeds by that same selective action of the bubbles upon the metal particles as against the gangue that is described in the patent in suit, and I just want to read three or four lines from Judge Bradford on that same subject at

the bottom of page 46 of his opinion, where he said, as to these two froths and processes:

"In order that the bubbles in the pulp mixture may come in contact with the metallic particles, there must be such movement between them as cannot be wholly accounted for by selectivity as between them * * *. That is to say, they won't jump together as though electrified. They must be moved together.

* * * and their movement so far as not accounted for by selectivity is the result of agitation; and whether such agitation results from the stirring or beating of the mixture or the forcing or admission of air into it is immaterial; for what this court is dealing with is not an apparatus patent, but a process patent."

In the first patent in suit there is no limitation as to specific apparatus. Just before the claims occurs the statement:

"The nature and arrangement of the apparatus used may be varied without departing from this invention."

Substitute another way known in the art for aerating and agitating, and you have the defendant's operation.

How can the agitation of this first patent in suit be limited to mechanical agitation, when it has two illustrations of what it means, and one of them is not mechanical agitation? That flies in the face of every principle of construction of a patent, and demonstrates that the Supreme Court was not construing this patent in the matter of agitation, for it took no note of that fact.

THE MACHINE-DRILL first was introduced in 1838 by J. M. and John N. Singer, and was actuated by means of a cam that raised the drill, which on being released, fell by gravity on the rock. Drills of this type were called 'drop-drills.' They could only be used in boring vertical holes. Several of these machines were employed in canal work in Illinois, but were cast aside after about two years, not being satisfactory. The first steam-drill was constructed by J. J. Couch and Joseph W. Fowle in 1848. In this machine the drill-bar passed through the piston of the engine, and was alternately drawn back and thrown against the rock. It was used but a short time. Mr. Fowle then experimented with a drill in which the bit was solidly secured to the piston-rod, and although he made five different machines, he was unable to attain the success he expected and gave it up. In 1861 M. Sommeiller invented a piston-drill similar in principle to that of Fowle, but of different construction. To this machine he successfully applied compressed air—the first to use this means of operation. Messrs. Brooks, Burleigh, and Gates made a machine similar to that of Couch and Fowle; it was used in the Hoosac tunnel, though not a satisfactory drill. In 1866 Charles Burleigh bought the Fowle patent and made a new machine of the solid-piston type with few parts and strong enough to bear the shocks of the work. This was the first really successful machine-drill, and in some of the older mining districts machine-drills of any make are still called 'Burleighs.'

The machine-drill and nitro powder have made a vast difference in the economy of mining.

Concentrates

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

PERCUSSION figures are the six-rayed stars produced in some minerals, notably the micas, when a crystal is struck or impressed by a blunt point.

PRIMERS for blasting should never be made in the same place that dynamite is stored, nor should the detonating caps and powder be kept in the same magazine.

BECAUSE dynamite occasionally burns without exploding, the fact should not lead to the conclusion that there is no danger when dynamite is burning; it sometimes explodes as well.

DENTAL GOLD is very porous, and when particles of it are hammered together they will adhere and form a solid mass, but there is no evidence that nuggets found in placers were ever formed in this way.

TIN has a peculiar property not possessed by any other mineral, known as the 'cry' of tin. This name is given to a peculiar crackling or squeaking noise emitted by a bar of tin when bent, or bitten by the teeth.

AT THE FALCON MINE, in Rhodesia, ore containing $2\frac{1}{2}\%$ copper and \$6 gold per ton is treated as follows: crushing by Nissen stamps; concentration on vanners; re-grinding in tube-mills; flotation; sintering of the concentrate; and smelting in blast-furnaces.

AUTOMATIC ore-feeders in stamp-mills are considered by a few old-fashioned people to be no improvement on hand-feeding with a shovel. A man who can feed a stamp-battery as well with a shovel as it is done by an automatic feeder would be worth more doing something else.

A TEST for the presence of gypsum in water may be made by placing the water in a test-tube to the depth of two inches and adding a little barium chloride; if a white precipitate is formed that does not re-dissolve on the addition of a little nitric acid, calcium sulphate is present in the water.

CLEAVAGE in minerals is a property that permits a crystal to split along any plane having the direction of the cleavage. Mica is a mineral possessing this property in an eminent degree. Parting, in crystals, is different from cleavage, and can only take place on a plane that is the surface of twinning-lamellae.

BORAX is obtained chiefly from the mineral colemanite, a hydrous calcium borate, containing when pure, 50.9% boron trioxide. The ore is often mixed with aluminous and calcareous impurities, in consequence of which it is usually graded at the mines before shipment, the first grade running about 30% and the second 20%. The

price is \$1 per unit of boron trioxide contained. The present nominal quotation for crude borate mineral is \$30 per ton. About 65,000 tons is produced annually in the United States, the most of which is from California.

CARBORUNDUM is an artificial compound containing 32% of carbon and 68% of silicon, and is a product of the electric-furnace. It is used as an abrasive, in the manufacture of grinding-wheels, and for sharpening-stones of many degrees of texture, from coarse to razor-hones.

ORE-POCKETS beneath a mine-level at a shaft are generally cut adjacent to the shaft, but in the case of a shaft having a low angle of inclination the pocket may be cut back some distance from the shaft, leaving a block of solid rock between, connection being made with the shaft below.

THE SAFETY DEPARTMENT of the Industrial Accident Commission in San Francisco has introduced safety nets for buildings under the course of construction. It has been found that the law calling for temporary flooring of buildings is impracticable. The distance to the floor is too far. The safety net supplies the need, for a man falling into a net is uninjured. The cost of the net is nominal; it is easily adjusted and can readily be transported from one place to another. It is similar in character to those employed by fire departments in the large cities to catch persons jumping from burning buildings.

FLOTATION has been tried on a gold-bearing arsenical pyrite ore from the Barberton mine in the Transvaal. Fine-grinding to 150-mesh and cyaniding gave only 45% recovery, roasting and cyaniding gave 82.5%, gravity-concentration and cyaniding gave 70%; flotation tests with various oils in neutral alkaline and acid circuits were made by F. Wartenweiler on the Rand in an agitation-type machine. The best results were obtained in a slightly alkaline solution, the ore being crushed to 90-mesh, and treated with wood creosote and paraffin oil. The middling and tailing were treated by direct cyanidation; the concentrate by roasting, amalgamation, and cyanide, giving 87.1%.

EAR-DEFENDERS, designed by artillery-men in Europe, are being tried in stamp-mills on the Rand to lessen the effect of the sound on the ear-drums of millmen. The apparatus consists of two small vulcanite plugs, shaped much like the pawns used in a game of chess, and fitting into the ears. A hole is made through the length of the pieces, and at the enlarged bell-mouth end a fine wire-screen is fixed. This screen breaks the waves of sound. At the Knights-Deep mill (120 stamps) it was considered that a broken stem or any unusual noise was more easily detected when wearing the defenders. Also, hearing becomes normal quickly after leaving the plant. The use of cotton-wool in the ears is not always safe, sometimes causing obstructions later on.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

PLATTEVILLE, WISCONSIN

LABOR FAMINE IN WISCONSIN ZINC FIELD RELIEVED.—HEAVY OUTPUT MAINTAINED.

Steady prices, regarded as satisfactory by leading operators in the zinc field of Wisconsin, were the main incentive toward an exceptionally good showing for February, a month not usually noted for standard records. The weather was uniformly good and roads were in fairly good condition for hauling, enabling the outlying producers to reach track with little difficulty. Labor stringency was much relieved by the influx of many foreigners attracted by the high scale of wages being paid to all classes now in demand, at the mines, and power service was uninterrupted following the completion of improvements and additions to the main service corporation at Galena, Illinois; representing increased investments to the amount of about \$500,000; and now well equipped to carry any load the zinc mining industry may impose upon the Inter-State Light & Power Co. (H. M. Bylesby & Co.) To further enhance the facilities of rapid ore handling the State Railway Commission practically compelled the Chicago & Northwestern Railway Co. to provide a branch from the main line of the Galena division to the New Diggings district and preliminary surveys, the securing of the right-of-way, and the actual construction were begun to the extreme delight of nearly all the leading operators in this and the Benton district, and from which section is coming better than half of all the ore now being produced. Here, too, is found the greatest amount of actual development of new mines and the proving of large tracts of virgin territory upon which the margin of anticipation has broadened with the scope of the enterprises undertaken. Without undue pressure from outside sources the building of a short line must prove mutually beneficial to miner as well as carrier.

Standard 60% zinc ore opened the month of February at \$75 per ton base and some premium grades called for figures nearer to \$80 per ton. Refining plants discontinued shipments for a time, expecting better offerings, and in this they were not disappointed nor had they long to wait. Advances in price were made rapidly and with generous strides from the 3rd to the 10th of the month, when standard commercial blende held at \$87 per ton base, with premium grades at \$90 and the range on seconds and medium grade holding closely at \$85 per ton base. From the 10th to the 17th, no material change was witnessed but the high tide of prosperity again rolled over the field from the 17th to the close of the month with the base price at \$90 per ton, for premium and 60% ore and no changes on demand for the inferior grades. Refiners closed out entirely at the higher figures and profits were scored on a scale exceeded but once since the War sent spelter ore soaring skyward. The cleaning up of all high-grade product followed a sharp, if brief, season of accentuated competition between smelters that make a specialty of buying up only high-grade material readily convertible into metal. The less pretentious corporations represented in the field were practically squelched while the big boys were slamming each other around and the supposition was general among those well informed that the better prices were pulled down on 'gentlemen's' agreements to a greater extent than was given out for public consumption. Low-grade producers did not fare well the first half of the month, and then only found one of the large buying companies

offering an outlet, the New Jersey Zinc Co. relieving a congested condition in camps where unidentified producers seek offers in open market. The output of the Linden district switched entirely to the Mineral Point Zinc Co. but it is pointed out here that the big eastern corporation is determined to freeze out the local refining company, and in this purpose seems to have succeeded admirably.

There was a considerable reserve of low-grade zinc ore found in the field at the close of the month but producers exhibited no anxiety regarding the future, the very atmosphere appearing surcharged with optimism. Much difficulty was experienced during the month in securing cars for immediate loading, especially in the Benton district where individual groups of mines made phenomenal weekly runs in ore recovery. This was exceptionally true of the Frontier Mining Co., which at times shipped as high as 20 cars of ore in a single week, and this under peculiar advantages guaranteed through contract arrangements with the Grasselli Chemical Co. The Frontier Mining Co. has been paying 24% dividends annually and in the past two years graciously contributes an extra 10% occasionally in addition to the generous liquidation just mentioned. The company paid \$15,000 income State-tax for 1916 and has been exceeded in this respect by several of the other leading mining corporations now engaged in zinc mining in the Wisconsin field. An official of the Frontier Co. asserts, with mild reserve, that the mines now in operation for his company with new producers just brought up to shipping form will be producing 1000 tons of zinc ore concentrate weekly. The Frontier ores are all below 50% zinc assay but low-grade ores have been receiving distinguished consideration. One of the leading buyers of the field submitted offerings upon request as follows: 50%, \$55 per ton base; 45%, \$45; 40%, \$40; 35%, \$32; and 30%, \$27. In matter of grades the Wisconsin field runs the gamut of all the grades quoted, with intermediate assays, and it is a safe assertion that the output of no two mines engaged in producing zinc ore in the Wisconsin field runs uniformly on grade, even on the same range.

The real sensation of the month was performed in the offerings made to lead-ore producers. The price at the beginning of the month held slightly in advance of \$90 per ton, for 80% ore. The gains in quotations were made from day to day without recession at any time until in the closing days of the month offerings held at close to \$125 per ton. The sold-up condition of the pig-lead market was mainly responsible for the extraordinary leaps accomplished in the markets but production has not kept pace with the demand and experienced miners claim now that it is not unreasonable to predict that lead ore will be commanding \$150 per ton before midsummer. In the Wisconsin field producers cleverly resorted to waiting tactics, and even in the face of stiff advances refused to part with their product. Only as the price neared the high mark reported, did some consent to deliver and then only a portion of the ore held ready for shipment. The advent of spring weather will enable many small operating companies to invade shallow diggings for pocket and float-lead where washing can be conducted in the open.

Carbonate zinc-ore producers lost the only outlet for their product offered from outside sources, and such ore as was offered for sale was delivered through the ancient and honorable channel provided by the Mineral Point Zinc Co. Many small operators are engaged in rigging up plants for outdoor

cleaning and a better output is anticipated for this season. Pyrites remained in good demand at high prices, but the high offerings for zinc and lead ore, and the scarcity of cars for loading, determined refiners to devote themselves exclusively to the prompt shipment of zinc ore and several thousand tons of fines held at separating-plants were carried over.

Deliveries shown for the month of February, by districts, cover the period from the 1st to 24th, inclusive.

Districts	Zinc, lb.	Lead, lb.	Pyrite, lb.
Benton	20,000,000	152,000
Mifflin	4,578,000
Galena	3,786,000
Hazel Green	3,282,000
Cuba City	3,184,000	2,622,000
Linden	2,928,000	120,000	240,000
Shullsburg	2,328,000
Platteville	2,322,000	50,000
Highland	560,000
Potosi	328,000
Montfort	172,000
Mineral Point	72,000	238,000
Total	43,540,000	322,000	3,100,000

The gross recovery of concentrate of all grades for the month exceeded 40,000,000 lb.; net deliveries to smelters from refineries and from mines to smelter direct and under contract, 21,250,000 lb. The Mineral Point Zinc Co., operating with two reduction-plants, was tied up for a time overhauling buildings and machinery and did not make the fine showing for which this concern is noted, sending only 2,316,000 lb. of high-grade calcined ore to smelter at DePue, as against over 6,000,000 lb. delivered during the month of January.

Briefly summarized, the outstanding performances in the field during February find the northern districts acquitting themselves ordinarily while all the big doings are found in the camps south of Platteville. In the Cuba district the two refining-plants have been in constant operation with uniform results. Benton boasts several new producers and a big drilling-out program, by the Frontier Mining Co., that has resulted practically in the establishment of three new zinc ore producers: Bull Moose No. 2; Hird mine No. 1; and Hird No. 2, for which a complete rig will be provided to be in operation prior to June 1. For the Wisconsin Zinc Co. a new wet mill has been built at New Diggings at a cost of \$10,000; a mammoth warehouse to store supplies for all mines, mills, refining-plants and boarding-houses. For the Vinegar Hill Co. a new producer was brought in with equipment and an adjoining property developed up to the producing stage to be connected with the Meloy mine and mill. The New Jersey Zinc Co. began the development of the Hoskins mine, also in the New Diggings. New producers are brought into co-operation with the Longhorn, C. A. T., and Champion mines, for the Wisconsin Zinc Co. The branch railway into this district will boom the district and give a great impetus to the opening of new properties. Whereas two years ago the camp was little known as a mining centre, today over 1000 miners find employment here, and there is a constant, as well as an insistent demand for more men, not less than 500 being required. The Shullsburg district is experiencing a re-awakening. The knockers have had their day and outside talent is beginning to assert itself. In the Galena district the new Birkbeck mine is performing steadily with good results. The Black-Jack and North Unity report regularly and the Graham mine, a new Vinegar Hill project, is having a tough water-fight that only time can bring to a successful conclusion. No changes are shown in the Hazel Green district. Never in the history of mining in this region has there been such activity as at present, and the outlook is for a long continued career of prosperous mining regardless of War conditions.

VIRGINIA CITY, NEVADA

CON. VIRGINIA AGAIN ATTRACTING ATTENTION.—ACTIVITY ALL ALONG THE COMSTOCK.

Important developments are being made on the Comstock Lode, and the outlook for the coming summer is more encouraging than it has been in many years. A short time ago a small vein was cut on the 2700-ft. level of the Consolidated Virginia mine, in the south-west drift from No. 2 west cross-cut. Driving on this vein has shown it to increase in size and value. The assays, at first low in grade, have become higher as the work advanced, and now run from \$5 to \$20 per ton and over. Particular significance attaches to this new find, as it is in a large block of unexplored territory and its possibilities are considered great. In 1873 a vein was cut in a drift run north from the 1200-ft. level of the Gould & Curry mine that passed through the Best & Belcher and entered the Con. Virginia. This vein was small at first and the ore of nominal

COMBINATION SHAFT, COMSTOCK LODGE.

value, but as the work proceeded the vein increased in strength and the assays began to mount. Soon it was worth \$60 per ton, and later ran into the hundreds of dollars per ton. For two years development proceeded, blocking out the most wonderful mass of high-grade ore the world has ever known. With feverish activity the work proceeded under the direction of that astute superintendent, James G. Fair. The strike developed into the 'Big Bonanza,' and produced hundreds of millions of dollars. The stock increased so rapidly in value and to such high figures that, in order to keep it within reach of the speculating public, the property was divided into the Consolidated Virginia and the California mines, and the capital stock also was greatly increased, but notwithstanding this, the stock still had a market value in January 1875, as high, as \$700 per share and that of the California mine \$780 per share. The Big Bonanza was finally exhausted, but later a second ore-body—the 'Little Bonanza,' little only relatively—was found, and produced enormously. From the Big Bonanza the stockholders received: from the Con. Virginia \$42,120,000 and from the California \$31,050,000. It is not probable that the Con. Virginia has found another Big Bonanza, but miners who know the Comstock best hesitate to place any sort of limit to the possibilities of the great Lode—"they are," as Fair once said, "without limit, my son."

The Union is sending its ore to the Mexican mill, and is also milling ore from a stock-pile accumulated on the surface. Some excellent ore is coming from the 2600-ft. level of that mine. On the 2700-ft. level, exploration continues with encouraging results. The Mexican has placed an electric hoist on the 2500-ft. level at the winze to hoist from the 2900 level, and will begin development there as soon as practicable.

In the Sierra Nevada good headway is being made on the 2400, 2500, and 2600-ft. levels. There is some ore but thus far,

low-grade. The old Andes mine, lying up the slope back of the Con. Virginia is stoping ore on the 350-ft. level.

The Pumping Association is cleaning out the Mexican-Ophir winze to the 2900-ft. level and cutting out a station.

At the Gold Hill end, the Yellow Jacket is working ore from the upper part of the mine, and placing new equipment in the mill. The Alpha and Imperial are following small veins of rich ore on the 200-ft. level, working from the Imperial shaft. The Chollar-Potosi is being worked by the Comstock Leasing Company, it is said, with good results.

Everything considered, the future of the Comstock looks better today than it has for thirty years, and those interested are correspondingly jubilant.

WINNEMUCCA, NEVADA

IMPORTANT DEVELOPMENTS IN NUMEROUS MINES TRIBUTARY TO WINNEMUCCA.

The Helen Betty Mines Co. has installed pumps and other equipment at the Mazuma Hills and Mazuma Hills Extension mines, preliminary to extensive operations. The Darby mill has been placed in commission on ore from the dumps of the two properties. The mill has been completely overhauled and more equipment provided. The Helen Betty Co. recently took the mill and mines under bond and option. The property is at Vernon, in the Seven Troughs district.

Barret Springs, nine miles west of Winnemucca, is attracting attention, with several operators preparing for early shipments. The ores are largely silver-bearing, but in some instances a fair gold content is reported. Shipments will be to Winnemucca by mule-team or auto-trucks, and from here by rail to custom smelters.

The Seven Troughs Coalition Co. is working vigorously the Fairview gold mine, near Vernon. Arrangements have been made to install more machinery, and the shaft will be sunk deeper. On the 700-ft. level the main vein has been driven on for 100 ft. and shows a full width of milling ore, with seams of high-grade ore that will be shipped.

The Nevada Humboldt Tungsten Mines Co. has been formed to operate tungsten deposits at Mill City. The vein has been opened for 120 ft. by drifts from the main tunnel and is 5 ft. wide. It is said to assay 4% tungsten.

The long-awaited equipment for the tramway of the Rochester Mines Co. has arrived and within two weeks the management expects to be shipping ore to the mill by the new system. Northerly drifts from the 650-ft. level are in ore averaging 14 ft. wide, and the drifts from the 800-ft. level are showing wide faces of mill ore. North and south drifts above the 250-ft. level are advancing on a vein ranging from 6 to 7 ft. wide. The February output of the mine was \$38,000.

MONTERREY, MEXICO

RENEWAL OF MINING AND SMELTING IN NORTHERN DISTRICTS OF MEXICO.

The renewal of mining and smelting operations in north Mexico is becoming general. The large smelter here of the American Smelting & Refining Co., recently re-opened with J. R. Enlow, formerly superintendent of the company's smelter at Chihuahua, in charge. Simon Guggenheim and Edward Newhouse, directors of the American Smelting & Refining Co., and C. L. Baker, general manager of the southern department of that corporation, arrived here a few days ago on a trip of inspection of the company's properties. They are arranging for the re-opening of the smelter at Matehuala, State of San Luis Potosi.

The American Smelting & Refining Co. plans to operate its own trains between Laredo, Texas, and Monterrey for the purpose of transporting to its plant here coke and other necessary supplies, and to carry to the border the bullion from the

smelter. The de facto government of Mexico has promised the company to exercise unusual vigilance in keeping this stretch of railroad open so that its smelter operations will not be hampered. Military protection is also to be given the different mining properties from which the smelter draws its oil supply.

The Mazapil Copper & Mining Co., which is controlled by American interests, resumed the operation of its smelter and mines at Concepcion del Oro, in the State of Zacatecas, a few days ago. The American employees of this company were

MAP OF A PART OF MEXICO.

driven out of Concepcion del Oro several months ago by bandits and the property has stood idle since then until it was recently re-opened. The Coahuila and Zacatecas railroad, which connects Concepcion del Oro with Saltillo, is under military protection of the governor and is to be kept open for the movement of traffic to and from the mining camp.

GRASS VALLEY, CALIFORNIA

NEW MACHINERY FOR ALLISON RANCH.—EXTENSION OF NORTH STAR MILL.

Two electric pumps are in position at the Allison Ranch mine and unwatering of the shaft will start with completion of the power-plant. The workings have been unwatered to a depth of 75 ft. Frank Vestal has resigned the superintendency of the cyanide-plant at the Empire mine to take charge of the Allison Ranch mill. As soon as the shaft has been placed in shape for mining, superintendent C. A. Brockington expects to employ 150 men.

Preparations are being made for substantial additions to the Central mill of the North Star Mines Co. It is probable 20 to

40 heavy stamps will be added to the 40-stamp unit, and capacity of the cyanide-plant also will be increased. The old 40-stamp North Star mill will be dismantled. A heavy tonnage of ore is being drawn from below the 6000-ft. level of the Central shaft.

The Signal Peak Mining Co. has installed a Cornish pumping-plant at its property, two miles west of Grass Valley, and sinking of the shaft 200 to 300 ft. deeper will commence at once. Some good ore is reported to be exposed in the old workings. E. M. Taylor is manager.

The Eastern & Main gravel property, situated on the Blue Lead channel, between Quaker Hill and You Bet, has been taken under bond by Issac Ostrom for \$15,000. San Francisco capital is said to be chiefly interested. Driving of a bed-rock tunnel has started from Greenhorn creek to drain the channel. A. H. Turner of Colfax is the principal owner.

The Columbia Consolidated Co. has arranged to double the capacity of its 10-stamp mill near Washington. Ten new stamps will be installed as soon as the roads are in shape for heavy transportation, and more tables provided. The mine force is to be increased. Manager C. E. Klinker reports the property to be in excellent shape.

SUTTER CREEK, CALIFORNIA

NEW VEIN OPENED IN CENTRAL EUREKA MINE.—OLD EUREKA MACHINERY ARRIVED.

Despite the heavy rains, resulting in increased water in the mine, the Old Eureka shaft has been cleared to the 1700-ft. level and it is estimated that within six weeks' the shaft will have been unwatered and in thorough repair. Below the 1600-ft. level the shaft later will be enlarged from one compartment to correspond in size to the upper portion, but as the timbers are practically intact after their many years of submersion, it was decided to leave the timbers unchanged until conditions at the bottom of the old shaft could be examined. The two new motors for the hoist have at last arrived at Martell station, but it will be impossible to haul them over the new road into the mine until the damage caused by the recent storm has been repaired. A large quantity of rock has been used on the road leading from the county highway to the mine, but the heavy rains have so softened the foundation of the road that difficulty is experienced in taking in ordinary loads, and these new 300-hp. motors each weigh five tons, the heaviest so far installed in the county. Proof of the early-day richness of the Old Eureka mine is furnished by the frequent discovery of 'high-grade' cached behind timbers as the shaft-men proceed downward with their work. One specimen recently brought to light is said to contain several hundred dollars worth of gold, while smaller finds are a common occurrence. The new transformers are about to be installed and everything will be in readiness to put the new hoist into operation when the motors can be placed.—The North Star shaft has been unwatered to the bottom; the rapid progress made in re-opening this old shaft being due to the timbers being found in excellent condition. In fact, it has not been necessary to entirely renew a single set, although the mine has been idle for more than 26 years. The only caves encountered were at the point where the cross-cuts on the 600-ft. level passed through the veins. These caves will quickly be caught up and work will be pushed vigorously in proving the value of the ore-shoots known to exist in the South Keystone group of claims. John A. McIntire of Sacramento, one of the directors of this new company, has been on the ground this week with manager Chas. H. Colpe, directing some important survey work pertaining to future cross-cutting and development. The surface plant works satisfactorily.

The two new 5-ton 300-hp. motors for the Old Eureka mine were delivered at the property during the week and are now in course of installation and the transformers are being con-

nected up. Everything will be in readiness for the operation of the new hoist within a few days, after which the small hoist and temporary head-frame will be removed.

At the Central Eureka, the vein discovered in cross-cutting in the foot-wall for waste to use in filling stopes, is exceeding expectations both in size and value. This new orebody was unexpectedly cut on the 2500-ft. level and already has been driven on for 240 ft. and in that distance has given average assays of \$6 per ton. Since the discovery of this ore, it has been handled through the 2700-ft. level by using the intervening stopes and chutes, but now the 2500-ft. drift, filled when that level was supposedly worked out, will be re-opened for the more convenient handling of the ore. The cross-cut run in from a point 15 or 20 ft. above the bottom of the shaft, which has just been sunk to 3400 ft., already has reached the orebody encountered in sinking a few weeks ago and the ore is giving excellent assays.

Sinking for the present has been discontinued at the Central Eureka mine, where the shaft has attained a depth of 3400 ft. A station will be cut in the new part of the shaft below where the ore was found in sinking. Driving on this rock will soon be commenced, and the usual raises made and chutes placed.

The intention is shortly to begin sinking for another level at the Oneida mine, of the South Eureka Mining Co. Ore of good grade is being mined from the lower levels and there is talk of increasing the milling capacity at the Oneida. A good grade of ore also is being mined on the 1200 and 1600-ft. levels of the South Eureka property and the 80 stamps of that mill are in steady operation.

SALT LAKE CITY, UTAH

MILLIONS IN DIVIDENDS BY THE JACKLING COPPER COMPANIES.

At meetings of the directors of the so-called Jackling properties held recently, dividends were posted amounting to almost \$13,000,000, which will be distributed on March 31 to stockholders of record March 9. The dividends posted were on the Ray Consolidated, Chino, Utah Copper, Butte & Superior, and the Nevada Consolidated. With the exception of the latter two the dividends were the same as posted in December.

The Utah Copper will pay its stockholders the regular quarterly dividend of \$2.50 and an extra of \$1, which was the same as last quarter. This amounts to \$5,685,517 or at the rate of \$14 per share a year to \$22,742,860. With the present dividend the Utah Copper will have paid its stockholders \$57,901,493. Although shipments at the Utah Copper have fallen off during the past two months on account of the bad weather, the price received for copper has been higher so that the company is continuing to maintain its record of earnings which last year amounted to \$26 per share and on which \$12.50 in dividends was paid.

Chino Copper with 869,980 shares outstanding pays its stockholders \$2,174,950 or at the rate of \$1.50 the regular quarterly amount, and an extra of \$1. This is the same as that paid during the previous quarter.

Ray Consolidated will pay its usual quarterly dividend of 75 cents and an extra of 75 cents, the same as last quarter. This amounts to \$2,365,693.50 on the 1,577,129 shares out.

The Nevada Consolidated reduced its extra dividend. This quarter it will pay the regular dividend of 50 cents per share and an extra of 50 cents per share. Last quarter the extra was \$1. This amounts to \$1,999,457.

Butte & Superior also reduced its extra dividend. The last extra was \$5. The dividend posted today is the regular of \$1.25 and an extra of \$1.25 making a total of \$681,742.50 to be distributed to the stockholders.

The grand total of the properties posting dividends amounts to \$12,907,558.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALABAMA

Graphite properties near Pyriton, will be developed by the Great Southern Graphite Co., and the plant will have a daily capacity of 300 tons. The machinery has been purchased, and 120 acres will be mined. Officers have been elected as follows: H. O. Moore, president; F. J. Holberg, secretary; John D. Hutton, treasurer; A. W. Clark, general superintendent; Edward B. Van Keuren, construction engineer; all of Birmingham.

ALASKA

The copper ore shipped from Alaska in February is stated to have been worth \$4,099,001; lead ore, \$11,295; gold ore, \$182,667, and silver ore, \$76,472.

A shipment of 250 tons of tungsten ore from Alaska was sold to the Bilrowe Alloys Co. of Tacoma. This company is building electric furnaces for the manufacture of special alloys at Tacoma.

SEATTLE. The impression prevails that the next big placer stampede in Alaska will be to the Kuskokwim valley. A recent strike was made on Quin Hagak creek, where a miner took out \$800 in ten days, says the *Seattle Times*. Two natives assisted him. Good strikes have also been made on Canyon and Bear creeks in the same region, about 80 miles up the river from Bethel. This is according to Duncan McMillan, who recently came from that district.

"It is contrary to the policy of the trading companies in the Kuskokwim valley," says McMillan, "to have any news of strikes get to the outside world. I know very little about mining, but I believe that the country some day will support a great population. The natives and Laplanders are doing splendidly with their reindeer herds. Besides indications of placer gold, there are other minerals." Mr. McMillan has a cinnabar mine 125 miles up the river from Bethel. He says he was offered \$300,000, but is holding it for \$500,000.

ARIZONA

(Special Correspondence.)—The New Cornelia Copper Co. announces the opening of its town-site to the public. The town-site will be operated by the Ajo Improvement Co.

Ore shipments continue from the Hill No. 3 to the C. & A. smelter, at Douglas, at the rate of about a car a day, three shifts being employed.—Sam Clark, owner of the C. & A. No. 2, announces a strike of native copper on that claim. He is operating the C. & A. No. 2 and several other claims in the vicinity.

Mr. Gotthelf, of Los Angeles, is here inspecting the Mandan group with a view to lease or purchase the property.

Ajo, March 2.

CAVE CREEK. E. A. Howard is about to resume work on the Mormon Girl mine, at Cave Creek, in Maricopa county.

BISBEE. The Bisbee-Tombstone Copper Mining Co. is preparing to sink two shafts on its property west and north of the Warren district. One shaft is already down 50 ft. The other shaft will be sunk on the other side of the hill several hundred feet from the first.

JEROME. There is an unconfirmed report in circulation that in the Jerome Verde a mass of high-grade copper sulphide has been penetrated by a diamond-drill operated in the United Verde Extension Co.'s Little Daisy claim, on the 1400-ft. level. The new find is supposed to be the continuation of the ore-

body which was lost by faulting in the Extension mine. It is said that the ore runs from 15 to 20% copper.

KINGMAN. The first shipment of molybdenite concentrate was made from the Leviathan mill in Copper canyon March 3, the shipment going to San Francisco. The Leviathan company has a mill of 60 tons daily capacity, and has been making a 40% product. As soon as the weather moderates a larger output of concentrate will be made, the mill being handicapped by freezing water. Sinking below the 100-ft. level will soon be started. The mine is looking well. The orebodies have been opened 500 ft. long, without finding a break.

MIAMI. The Inspiration company during February hoisted a daily average of 18,269 tons of ore.

(Special Correspondence.)—A. C. Werden, manager of the Gold Ore Mining Co., reports successful tests by flotation at the laboratory of the Minerals Separation Co. at San Francisco. Tests show a concentrate of 30 tons into one and an extraction of 95%. The mill costs are estimated at \$1.50 per ton in a plant treating 100 tons daily, including royalty. Minerals Separation Co. claims to treat flotation concentrate, at a cost of about \$1 per ton, which would be less than 5c. per ton of crude ore. If this can be demonstrated to satisfaction of the Gold Ore Co. it is probable that the flotation-process will be installed. The cost of a 100-ton plant is estimated at \$45,000, which is less than one-half the cost of a cyanide mill of the same capacity.

The Big Jim cross-cut on the 600-ft. level has cut the vein and encountered a heavy flow of water that delayed operations. The vein was cut where the engineers had estimated, indicating that the dip and course are unchanged. It will require several days to drain the accumulated water on the 500-ft. level as well as the natural flow of the pent-up water in the vein below the 500-ft. level. Much interest attaches to the 600-ft. level, which Horace V. Winchell stated probably will double the value of the estimated ore.

Work has been resumed at the Telluride which adjoins the productive easterly end of the Tom Reed, where a large vein of high-grade milling ore has been developed on the Aztec Center claim. The Telluride has a strong vein which was prospected at a depth of 500 ft. The shaft will be sunk an additional 100 ft. Three shifts are employed under direction of J. H. McIver, who opened the ore in the United Eastern.

Shipments of bullion were made early in the week from the United Eastern and Tom Reed mines. The value of the two shipments, representing two weeks' run of the two mills, exceeded \$100,000.

Oatman, March 5.

(Special Correspondence.)—A strike of chalcopryite is reported on the Mile Wide Copper Co.'s property in the Tucson mountains. The ore averages 20% copper and the vein is 8 ft. wide on the 200-ft. level. Supt. C. E. Visel is driving along the shoot and will raise and sink. The controlling interest in this property is held by the Lyon, Singer Co. of Pittsburg.

Tucson, March 2.

CALIFORNIA

CARRVILLE. The Pacific Gold Dredging Co. is preparing for construction of its No. 2 dredge, which will operate on Coffee creek. It will be of same size and type as No. 1 which has been working for several months with satisfactory results.

DOWNIEVILLE. Work in the Gold Bluff-Oxford mine is to be

resumed, the owners of the Gold Bluff having agreed to extend the time for a payment on the bond.

DOWNIEVILLE. A bond has been given J. G. Sartorius by H. S. Tibbey et al, owners of the Brown Bear gravel property, on St. Charles Hill in Sierra county. By the terms of the bond, work must be commenced not later than May 15, 1917, and at least two shifts of miners must be employed; the wages of the employees and all bills must be paid at least monthly (they may be paid semi-monthly if desired) and the owners of the property are not to be held liable, under the employers liability act, for the injuries or death of any of the employees. The bond was given in February and was put on record by Mr. Sartorius last week. The bond is a resident of San Francisco.

(Special Correspondence.)—**FOREST CITY.** Under the management of W. F. Copeland work in the Bald Mountain and Bald Mountain Extension properties is being vigorously carried on. The Bald Mountain tunnel has been cleared for 1200 ft. and a cross-cut from this point has intersected an 18-in. vein of sulphide ore. The ore occurs in amphibolite, near the serpentine contact. Prospecting of the gravel channel is also in progress. The continuation of the Bald Mountain Extension channel is being explored by a tunnel from Rock creek. The mines lie near Forest City.

The tunnel at the Kanaka mine, near Alleghany, has advanced to a point 300 ft. in from the portal and is calculated to intersect the vein within 50 ft. On surface the vein shows a width of 18 ft. of fair-grade ore. A one-fourth interest in the property has been purchased from Ambrose Madden by Paul Proper of Oakland.

DOWNIEVILLE. The Rosenfeld Co., of San Francisco, has granted an extension on the bond of the Gold Bluff-Oxford group, according to word from the operators. The group has been under bond and option to Salt Lake capitalists for two years, in which time much development work has been performed and equipment installed. The property is near Downieville.

Downieville, March 9.

GARDEN VALLEY. The chrome mine in Garden Valley, which was closed on account of the bad weather, is being again worked. Several teams are hauling the chrome to the railroad at Placerville.

(Special Correspondence.)—The Rand Mining Co. of San Francisco that is working the June-Ione tungsten mine on Slickrock creek eight miles north-east of Glennville, in Kern county, is equipping the property with a concentrating plant costing \$30,000, and having a capacity of 50 tons of ore daily. They estimate the average content of scheelite at 2%. A shaft has been sunk 40 ft., and an adit run on the vein 60 ft. Development is in progress. Work is to be resumed on the Cadillac group on the middle fork of Cedar creek, two miles north-west of the June-Ione. The scheelite in both mines is associated with garnet.

Glennville, March 4.

GROVELAND. A washout on the Argall ranch, at Second Garotte, three miles east of Groveland, on the Yosemite road, uncovered a quantity of gold. Without doing any mining work, the owner of the place picked up gold to the value of \$600 in the trench cut by the water. He will work the ground-miner fashion, and expects to locate the source of his new-found wealth.

HODSON. The directors and principal stockholders of the Royal Consolidated mines are endeavoring to re-organize the company with a view to resumption of operations, and to make an arrangement whereby the creditors may be satisfied.

OROVILLE. Horace Onyette has been recruiting a force of experienced dredge-men for service on dredges at Iditarod, Alaska.

PLACERVILLE. It is reported that the Church-Union mine, to-

gether with some adjoining property, five miles south of Placerville, has been sold to H. H. Long of Mill Valley, Cal. The old Church-Union mine has been working for several months past, after years of idleness. It is said the old Springfield mine, half a mile south of the Church-Union is also to be unwatered. The Springfield mine was last operated by A. Harpending, nearly 20 years ago.

WASHINGTON. C. E. Klinker, general manager of the Columbia Consolidated Mines, is to add ten stamps to the Ocean Star mine and as soon as weather permits will double the force of men.

The report of State Oil Inspector, R. P. McLaughlin, for the week ended March 3 shows 24 new oil-wells started, 20 to be inspected for the test of water shut off, 23 being drilled deeper or re-drilling, and four to be abandoned.

Articles of incorporation of the Cerise Gold Mining Co. of Willows, Glenn county, organized for carrying on a general mining and milling business, have been filed in the Secretary of State's office. The incorporators are: Z. E. Simpson, Orland; H. E. Simpson, Orland; Frank Freeman, Willows; Charles L. Austin, Wilbur Springs; and John Schribner, Orland.

In 1914 the New Idria Quicksilver Co., in San Benito county, received an average price of \$48.31 per flask for its quicksilver. In 1915, due to the increase in demand, the company received an average price of \$74 a flask. In 1916 the price received was \$89.57 a flask. That is more than double the average price received in 1913. It cost New Idria Quicksilver Co. between \$47 and \$48 a flask to produce its quicksilver.

The following applications have been made to the State Water Commission for the appropriation of water for mining purposes:

John Terribilini, of San Bernardino, 40 miner's inches of the water of a tunnel in a mountain in Riverside county for gold-mining purposes.

Byron N. Russell, of Weed, 3 cu. ft. per second of the water of Dutch creek tributary to Beaver creek in Siskiyou county, for placer mining. It is proposed to conduct the water three and one-half miles by a ditch from the point of diversion to the place of use at a cost of \$1000.

The Table Rock Mining Co. of Table Rock, 400 miner's in. of the water of south fork of Slate creek tributary to Slate creek in Sierra county for purposes of sluicing gravel. A ditch 1096 ft. long will be required to carry the water to the place of use.

COLORADO

The Gilpin County Mining Association has taken up the problem of the relation of the small ore-shippers to the smelter, with a view to securing legislation that will define more clearly what the ore-shipper is entitled to receive from the smelter and what the charges for treatment shall be. A shaft is also aimed at the 'time-honored' practice of the smelters converting to their own use minerals in the ores for which no accounting whatever has been made in the past.

LEADVILLE. The new ore-shoot recently found in the Ontario tunnel, near Leadville, has been cut for 40 ft. in the drift. It is believed that another shoot lies about 100 ft. farther on, that was passed through by the Tiger shaft, in the early days of the district.—The Jamie Lee has suspended operations until additional pumping facilities can be provided. The shaft was down 601 ft. when the last heavy flow of water came in. Diamond-drilling is in progress on the lowest level of the mine, not far from the shaft. The sudden heavy influx of water is regarded as indicative of the proximity of ore.—The leasing company operating the Fortune mine below the level of the Yak tunnel also has a heavy flow of water that is believed to come from some old workings. A sinker in the Resurrection winze is lowering the water in the Fortune workings.

(Special Correspondence.)—The Gold Crown mine is nearly

ready to commence operations.—The Mineral Farm will again be in operation next month and the manager C. R. Wilfly looks forward to opening up good orebodies and hopes to solve the peculiar problem of the ore conditions. It means big things or nothing on Mt. Hayden.—The Mountain King property under lease to Sheriff Krisher, is a steady shipper of lead and zinc ore and as the mining of the same requires no powder, it makes the mining cheap.

Ouray, March 1.

SILVERTON. An important development is reported made in the Pride of the West mine, where a large vein of ore running 55 oz. silver, \$70 in lead, and \$20 in gold has been struck. The main adit was run 2000 ft. years ago, and when, after a long idleness, work was resumed last fall, a good deal of repairing and cleaning up had to be done. Then a drift was started from a raise in 1250 ft. from the portal, with the result stated. Ore has been hauled on sleds to the new Green Mountain mill during the winter. The Pride of the West and the Green mountain mine are both under the management of A. W. Harrison. The mines are in Cunningham gulch, six miles from Silverton. Slattery, Delsant & Gillette, lessees of the Highland Mary mine, have made repairs and the necessary changes in the mill, and will begin milling ore about March 10. During the winter they have packed their ore to the railroad for shipment to smelters.

IDAHO

The output of Idaho's mines in 1916 reached a total of \$49,102,693, which is the largest and highest for a year in the history of the State, according to the official report of Robert N. Bell, State inspector of mines.

The metal content of the mineral and bullion shipped, from statistics available, is as follows:

Lead, pounds	366,594,000
Zinc, pounds	98,700,740
Copper, pounds	8,052,725
Silver, ounces	12,205,132
Gold, ounces	58,979
Tungsten ore, pounds	120,000

These figures are based on gross metal-contents of the ore as shipped, without discounting for loss in smelting, which is a variable amount and hard to determine and to some extent made up with by-product recoveries that are not paid for by the smelters.

These figures maintain Idaho in second place in lead production among the States of the Union and are a splendid indorsement of the progress and permanence of the mining industry in this State.

The estimated dividend distribution of the year aggregated about \$11,500,000, which is more than the total output of the State as recent as 15 years ago and was credited to 14 mines, nine of which are lead-silver and zinc producers in the Coeur d'Alene, and five in south-central Idaho, situated in Boise, Blaine, Custer, and Lemhi counties, and include a gold, a copper, and three silver-lead producers. That the dividend distribution was not larger is due to enormously increased operating costs, including labor and material. The operators of northern Idaho volunteered an advance in wages based on a sliding scale.

During the year there were employed in mining and milling operations, according to statistical reports received by this department, with a conservative estimate of the remote parts of the State, 7500 men, of which 5300 are credited to Shoshone county.

The total fatalities were 13. The number of serious accidents, involving a loss of time in excess of 14 days, was 219. The number of minor accidents, involving less loss of time, was 672.

In the three months of operations ended February 28 the

Rex Consolidated Mining Co., operating in the Coeur d'Alene produced 2200 tons of concentrated ore. Raymond Guyer, general manager, says that the net profits on this ore were \$53,000. The greater part of the product was shipped to the leaching plant of the Anaconda Copper Mining Co. at Great Falls. The rate of milling will be increased to 275 to 300 tons daily by the end of March.

Extraction has been high, averaging about 86%. The concentrate contains 35% zinc, 11% lead, and 5.2 oz. silver to the ton. Another product contains 48% lead and 19 oz. silver to the ton.

KANSAS

BAXTER SPRINGS. The Lucky Kid Mining Co. has bought 40 acres of the Hocker land, three and one-half miles south-west of Baxter Springs. This company includes in its personnel J. M. Smith of Webb City; J. G. Marcum, of Joplin; W. A. Moses, L. E. Moses, and A. L. Harroun, of Kansas City. Over a year ago it acquired the lease just east of the Montreal mine at Century, and recently has been making heavy turn-ins from this property. On the Hacker lease drilling indicated the presence of 40 ft. of ore at a depth of 160 ft. Assays run from 10 to 40% blende.

MICHIGAN

During 1916 the copper content of the ore of the Mass Consolidated increased 2 lb. per ton—from 14.35 to 16.51 lb. Even this advance, however, does not bring it to a point where it could be considered an average Lake Superior mine. The only three mines of importance in that district, whose yield per ton was less than that in 1915, were the Centennial, Isle Royale, and Osceola. The only one which has been a money maker is the Osceola, which has been able to do so because of the large tonnage of rock that it handles.

Treating 300,000 tons of ore per year, Mass Consolidated could hardly hope to get its cost down to less than 12c. per pound on rock of this grade, even under normal conditions. This would mean earnings on a 5,000,000-pound output of about \$1.50 per share on 15-c. copper. However, the fact remains that the change was in the right direction.

MINNESOTA

Two leases of iron mines of the Great Northern ore properties in northern Minnesota, involving an estimated consideration of \$110,000,000 have been sold to the Inland Steel Company and Jones & Laughlin of Pittsburg, according to a story printed in the St. Paul Dispatch.

MISSOURI

GALENA. The largest zinc-ore shipment that has been made from the Galena district for many years was made last week, and consisted of 30 cars. The record turn-in has not been approached for more than three years, when 25 cars were sent out.

The George McCullagh Mining Co. made the largest shipment, with nearly 250 tons, and several other companies made large shipments.

There was a brisk demand for low-grade ores last week. The Empire Mining Co. sold ore for shipment before March 10 that assayed only 40% metallic zinc. The ore contained 18% iron and was sold on a basis of \$80 per ton.

Most of the ore sold brought \$85 per ton. The James Murphy Mining company received \$88 for its ore, and that price is believed to have been the record for the week here.

Lead sales totaled more than 105 tons. They were made in small lots and the Southside Mining company made the largest lead turn-in, with a little more than nine tons. Lead brought \$115 per ton last week.

MANSFIELD. The R. S. & T. Mining company sold two carloads of silicate last week to a Joplin buyer.

The Mansfield district has a revival of mining, due to re-

cently discovered rich land near the town. Years ago a little lead mining was done, but blende and silicate is a new discovery.

The R. S. & T. company has 1600 acres of land in the ore belt. Surveyors are laying off the land into 40-acre tracts, which will be leased to prospective mining companies. Other companies have been formed and promise to place Mansfield on the map as an ore producing district.

The R. S. & T. company is installing new machinery in a mill on its lease and soon will be in a position to increase its ore production to a considerable extent.

MONTANA

BUTTE. Progress has been made in the bulkheading of shafts in the West Colusa, Tramway and Leonard mines to check the destruction by the fire in the workings of the latter property. The blaze and the resultant gases are daily being confined to smaller and smaller areas. The situation is well in hand, but the fire is resulting in a decrease in the normal production of 900 tons of ore each day at the Leonard and West Colusa.—Many men are constructing bulkheads on the lower levels of the Tramway, but the full production of 1500 tons per day could be kept up should the weather moderate sufficiently to make it possible to handle the ore, says John Gillie, general manager of the A. C. M. properties in this community.

The regular output at the Leonard is 1300 tons per day and of the West Colusa is 1400 tons daily. One-third of the production at each of these has been decreased because of the fumes from the fire in the Leonard, thought to be the appearance on lower levels of the great blaze which started in the mine in 1906 and which was thought to have been safely confined behind bulkheads.

LUBBY. During January the Rose Consolidated recovered gold worth \$3000, and tungsten \$2000, from 25 tons of ore daily. The extraction was 85% of the gold and 75% of the tungsten.

MARYSVILLE. The Boyer Bros., who have been prospecting and mining here for years, recently began prospecting near the Gloster-Piegan group of claims and north toward the Big Ox group, and have uncovered a blind lead. After sinking to a depth of 15 ft., the ore was found to be 6 ft. wide, 3 ft. of which assays \$50 gold per ton, and 3 ft. of it \$10 per ton. The Boyers sold their new find to the Barnes-King Co. for \$50,000, receiving part cash, the remainder to be paid by January 1, 1918. The ore is free-milling and its situation is good as regards milling facilities.

NEVADA

COALDALE. The development of the coal seams at Coaldale, 40 miles north of Tonopah, is to be undertaken by the Darms Coal Mining Co. There are known to be several veins of coal in the field, one of which is 2 ft. thick where cut in a shaft at a depth of 428 feet.

GOLDFIELD. Leasing was popular here in the early days of the district and to it was due the surprisingly rapid development of the mines. Later the principal properties were consolidated and controlled by a few companies. As the great mines began to show unmistakable signs of exhaustion, leasing has been again resorted to, and with gratifying results. The Goldfield Consolidated is leasing parts of its ground; the Florence has 14 blocks operating under lease, and other mines are being similarly worked, though on a smaller scale. The improvements in the flotation annex of the Goldfield Consolidated are completed, and ready to treat an increased tonnage of ore. In the Atlanta mine, A. I. D'Arcy, the manager, reports that a 5-ft. vein of ore has been opened for 100 ft. Of this 18 in. assays \$130 in gold and silver, and the remainder is worth \$38.

GOLDFIELD. In January the Goldfield Consolidated Co. mined 26,500 tons of ore at a net profit of \$19.50. During the month

1718 feet of development work was done. Operating costs were as follows:

	Ore handled, c. per ton	Total ore, c. per ton
Mining:		
Stopping	2.430
Development	28.388
Total mining	2.760	2.456

MANHATTAN. The new roasting and cyaniding equipment now being built at the White Caps mine will be completed and ready for operation early in June. The recent development in the White Caps mine is reflected in the activity of Manhattan stocks in the stock market.

The *Tonopah Miner* reports for the week ended March 3, that the Tonopah Belmont sent to the mill 2920 tons, the Tonopah Mining 2300 tons, the Tonopah Extension 2380 tons, the Jim Butler 750 tons, the West End 677 tons, the Rescue 255 tons, the Halifax 161 tons, the Montana 80 tons, the Midway 56 tons, the MacNamara 53 tons, and the North Star 53 tons, making the total production for the week 9685 tons, the estimated value being \$174,330. This valuation is calculated on the gross milling value of the ore.

TYBO. Seventy-five miners are to be put to work as soon as possible by the Louisiana Consolidated Mining Co. at the old Tybo mine, in Nye county. This property was acquired from the old Nevada Mines and Smelting Corporation, which produced \$5,000,000 between the years 1872 and 1879. The property consists of 125 acres. The shaft is 420 ft. deep, but practically all the ore that was extracted came from above the 300-ft. level. Barney Baruch & Co. is said to be the financial backer of the enterprise. A number of tractors and trailers will be used in hauling ore. There is en route a 165-hp. semi-Diesel engine, which will operate the compressor and pumps. Within two months it is expected that the property will be in full operation.

SOUTH CAROLINA

E. P. Earl & Sons have taken an option on several mines in the Ore Knob district and are planning development of the properties. Their office is at 165 Broadway, New York.

SOUTH DAKOTA

DEADWOOD. The Minerva mill, that for 40 years has stood near the mouth of Blacktail gulch, is being torn down and the machinery moved to the Custer Peak Company's mines near Englewood. The mill was first built to work the auriferous conglomerate of the Minerva mine, that is situated on the north side of the gulch joining the Gustin mine.

TENNESSEE

The Ocoee Copper Co., with a capital of \$1,230,000, has been incorporated by J. I. Carter, W. N. Whitaker, J. D. Mitchell,

I. G. Phillips and Raymond Wallace, all of Chattanooga; they have acquired 124 acres of copper-ore lands, and have leases on other similar property in Polk county. They have found high-grade ore in four places on the property, by means of the diamond-drill. They will sink a shaft and build a smelter.

TEXAS

(Special Correspondence.)—The mining of Fuller's earth is to be undertaken on a large scale near here by the Medina Fuller's Earth Co., which was recently incorporated with a capital stock of \$100,000. The company is headed by L. R. Parker of Aurora, Illinois, and associated with him are E. D. Henry and O. T. Gregory of San Antonio. They own 160 acres of land 14 miles west of the city, upon which there is a large deposit of fuller's earth. It is planned to install machinery and other equipment to cost \$50,000 for developing the property.

San Antonio, March 5.

UTAH

The Utah Copper Co. has \$15,000,000 cash on deposit to its credit. During January and February the earnings of the company averaged \$1,000,000 per week.

EUREKA (Tintic District). A new strike of lead carbonate ore is reported in the Lehi-Tintic mine, in North Tintic. The deposit is known to be 30 ft. wide and 8 ft. thick. It is worth \$25 per ton.—The Sioux Consolidated is cutting stations on the 800 and 1000-ft. levels, preparatory to driving to the body of copper ore that is believed to extend into this property from the Iron Blossom.—The Mammoth mine will resume shipments of ore as soon as the railroad can supply cars. The ore is high-grade.—The Lower Mammoth is mining lead-silver ore on the 1500-ft. level, and copper ore on the 1000-ft. level.—At the Victor mine, Earl McIntyre is shipping low-grade copper ore, which was dumped into the stope on the 300-ft. level for filling.—A strike was made recently in the Chief Consolidated mine on the 1800-ft. level, and high-grade ore is being mined. The output is 15 tons daily of ore running 800 to 1000 oz. silver.—The Gold Chain mine has 35 railroad cars of ore on hand waiting for cars which the railroad has been unable to furnish.

PARK CITY. Operators of the mines in Park City have posted notices of a raise of 25c. per day for all the men, the date of advance being March 1. Some months ago it was generally understood that when silver advanced to 75 cents or better there should be a raise in salaries. This was in compliance with statements made by various operators at times when metals were down.

The scale formerly paid was \$3.50 a day for shovelers, \$3.75 a day for machine-men, \$4 a day for timber-men, and \$4.50 a day for engineers.

Leaving out the lessees, there are approximately 1000 men employed in the mine and mills of the camp, the principal active properties being the Silver King Coalition, the Daly Judge, the Daly West, the Ontario, the Silver King Consolidated, the Naildriver, the New Quincy, and the California-Comstock.

WYOMING

The Copper Corporation has been organized to exploit copper deposits at Shawville. E. D. Miller is president, and S. C. Snead is secretary and treasurer.

CASPER. The Hall Oil Co. has spudded-in a new well on the north-west quarter of Section 22, Township 3, Range 1 West, in the Pilot Dome field, and the progress of this well in particular will be watched with interest by all who are acquainted with that oil territory. Otto Stock, of Casper, has the contract, which calls for drilling to a depth of 3000 ft. It is being done with a California standard rig that was erected and put into service last week. The machinery is well housed and heated and an abundant water supply is available.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

CHARLES BUTTERS is in New York.

MARK B. KERR has returned from San Sebastian, Salvador.

WALTER G. PERKINS has arrived in New York from London.

FRED. SEARLS, JR., has returned to San Francisco from China.

EDGAR RICKARD attended the meeting of the Canadian Mining Institute.

HOWLAND BANCROFT has been inspecting mines at Oatman, Arizona.

W. L. WHITEHEAD has gone to Antofagasta, Chile, on a geological expedition.

RUSH T. SHIL, of Los Angeles, has been in the Gold Reef district of California.

HENRY HAY has returned from Chile and is now at Long Branch, New Jersey.

WILLIAM B. DENNIS, of Corvallis, Oregon, was in San Francisco for a few days.

ALEX. BAIRD has been appointed assistant mine inspector for the State of Nevada.

D'ARCY WEATHERBE passed through New York on his way from London to Cobalt.

W. H. SEAGRAVE, recently resident in New York, has established himself at Seattle.

THOMAS S. CHALMERS, of Chicago, passed through San Francisco on his way to El Paso.

N. H. RUBY has gone to Mexico to take charge of a molybdenite mine near Magdalena.

R. J. JOHNSTON has returned to El Paso from the Creston-Colorada mine, in Sonora, Mexico.

A. F. KUEHN, director and acting manager of the Burma Mines, is here on his way to London.

SAMUEL S. FOWLER passed through San Francisco on his way from British Columbia to San Diego.

J. H. COLLIER, of Oakland, is on his way to New York and Montreal, preparatory to going to Alaska.

JOS. S. HENRY, of Castlemaine, Australia, is visiting California, after a professional engagement in Bolivia.

H. R. VAN WAGENEN, of Denver, Colorado, has left for Chile on examination work. He will be absent from the United States until about July 1.

WILTON J. CROOK has resigned the position of Professor of Metallurgy in the South Dakota School of Mines to re-enter the employ of the Pacific Coast Steel Co. at South San Francisco.

PETER NISSEN, the inventor of the stamp that bears his name, is also the inventor of the Nissen hut, now in general use by the British army in France. He is a major and was recently awarded the D. S. O. for distinguished services.

The deliveries of tin during February were fair, amounting to 3930 tons, of which 680 tons came via Pacific ports. Incidentally it may be said that shipments via Vancouver, B. C., are increasing for the reason that it is becoming more and more difficult to obtain cargo space at Singapore for direct shipment to New York. It has been ascertained that shipments to New York from the Far East by way of London not only have to encounter the submarine peril, but in addition have to pay double insurance at high rates. There is one insurance cost to London, and another to the United States. At the same time, importers are not cheered by the Vancouver shipments because of the long delays and the impossibility of keeping informed as to where the metal is.

THE METAL MARKET

METAL PRICES

San Francisco, March 13.

Antimony, cents per pound	24
Electrolytic copper, cents per pound	38
Pig lead, cents per pound	9.50—10.50
Platinum, soft and hard metal, per ounce	\$105—111
Quicksilver, per flask of 75 lb.	\$100—105
Spelter, cents per pound	13
Tin, cents per pound	50
Zinc-dust, cents per pound	18—20

ORE PRICES

San Francisco, March 13.

Antimony, 50% metal, per unit	\$2.00
Chrome, 40% and over, f.o.b. cars California, per ton	18.00—20.00
Magnesite, crude, per ton	8.00—10.00
Tungsten, 60% WO ₃ per unit	18.00—18.50
Manganese, 50% (under 35% metal not desired)	29.00
Manganese ore, 40 to 45%, sells f.o.b. Chicago at 58c. per unit with a penalty of 50c. per unit for more than 8% silica.	

EASTERN METAL MARKET

(By wire from New York.)

March 13.—Copper is unchanged. Lead is easier at 10 to 10.25c., with market firm. Spelter is quiet and steady.

SILVER

Copper sales last week totaled about 25,000,000 lb. Practically all of this metal was purchased by domestic consumers, and the major part of this business covered third quarter delivery.

The Braden Copper Co. in February produced 3,450,000 lb. of copper; the Kennecott Co., 7,090,000 lb.; the Shannon Co., 759,000 lb.; Anaconda, 25,000,000 pounds.

Shattuck Arizona dividend of 50 and 75c. extra will be paid quarterly, dates April 30 and March 31, July 20 and June 30, October 20 and September 29.

Butte & Superior, \$1.25 and \$1.25 extra. Three months ago it was respectively \$1.25 and \$5 extra. Payable March 31 to stock of record March 9.

Utah Copper, \$2.50 and \$1.50 extra. Payable March 31 to stock of record March 9.

Chino, \$1.50 and \$1 extra. Payable March 31 to stock of record March 9. Three months ago the same.

Ray Consolidated, 75 and 25c. extra. Payable March 31 to stock of record March 9. Dividend same as three months ago.

Nevada Con., 50 and 50c. extra. Three months ago it was 50c. and \$1 extra. Payable March 31 to stock of record March 9.

ALUMINUM

Quotations remain unchanged at 57 to 59c. for No. 1 virgin aluminum, 98 to 99% pure. The market is quiet.

ANTIMONY

Ore from South America is being offered for the first time since the break in prices last year. March shipment is quoted at \$2.30 per unit.

ORES

Tungsten. The tendency is toward higher prices, largely for the reason that stocks are low, with stocks en route to New York already under option. Wolframite has brought \$17 per unit. Supplies coming from South America are small for the reason that the Entente Allies are buying direct in Argentina, Peru, and Bolivia. A six months' contract is reported to have been closed in South America at prices equivalent to \$16.65, f.o.b. South American shipping-point, and further negotiations are in progress. Ferberite and scheelite have brought \$18 per unit according to a dealer.

Molybdenum. There is a shortage of ore which has put the makers of ferro-molybdenum behind in their contracts. Business in wulfenite is reported as \$2 per pound.

Antimony. Uncertain shipments from South America make business precarious. The quotation is \$2.30 per unit.

Eastern Metal Market

New York, March 7.

All the metals have been quiet in the past week, but prices are well-maintained. The copper trade is awaiting buying for the last half.

Producers of zinc believe that the price of the metal should be higher, or that the cost of the ore should be lower.

The A. S. & R. Co. advanced its New York quotation, March 2, to 9c., but independents already had been selling in excess of this figure.

Traders in tin are becoming nervous over the possibility of deliveries from abroad being interrupted, and 54c. per lb. has been done.

Spot antimony is easier around 30c., duty paid, meanwhile shipments are coming across the country slowly.

Steel plates and pig iron hold the center of the stage. The latter is advancing by leaps and bounds. Eastern Pennsylvania No. 2X is held at \$34.50 to \$36, furnace. The range of Southern iron has been as much as \$7. There is a general belief that the Government soon will be an active purchaser. The British Government has announced that it will terminate many shell contracts March 31, and one shell contractor already has laid off 1800 employees. The plate market is boiling. Eastern Pennsylvania makers ask 5.50c., Pittsburg base, for ordinary tank-plates, and 7c., mill, for ship-plates. The latter are sought for delivery in half a dozen foreign countries. Wire and wire products, and other products have been advanced. The Steel Corporation has withdrawn quotations on plates, shapes, and bars, preliminary to a probable advance in those articles.

The February production of pig iron amounted to 2,637,042 tons or a daily production of 94,180 tons, the lowest since August, 1915, the falling off being a result of the shortage of coke. The February output compares with 101,643 tons per day in January. Three more furnaces were in blast March 1—315 in all—than on February 1, but they were producing iron at the rate of 96,874 tons a day against 101,866 tons daily on February 1. Many furnaces have been banked intermittently.

COPPER

The market continues quiet, and in a general way has undergone but little change since a week ago. Reports have been persistent that heavy buying for the third quarter had been closed, but this is not true. For some weeks, quiet negotiations have been under way and these will eventually result in large export business. The large buyers, both domestic and foreign, are proceeding cautiously, and it is questionable if they will place business in any great volume at present prices. So far as the producers are concerned, their prices for deliveries prior to July are practically nominal. Both Lake and electrolytic for spot delivery are quoted at 36.25 to 36.50c., and these prices are asked for March, also. April ranges from 35 to 36c.; second quarter, 34 to 35c., and third quarter 31.50 to 32c. A little business has been done here and there, at or below the prices mentioned. Munitions work is on the wane in this country, as one result of which the Baldwin Locomotive Works, Philadelphia, Pennsylvania, recently laid off 1800 employees who had been engaged on such work. Great Britain has notified several manufacturers that she intends to terminate shell contracts on March 31, this being verified by a large Eastern steel and ordnance company. Despite this, a factor in the trade stated yesterday that some large brass business was expected to materialize in the near future. The February exports totaled 24,937 tons, about 90% of which was shipped from New York. It is estimated by an authority that since December 1, 1916, probably 30,000 tons has been lost through submarine operations. The London quotation for spot electro-

lytic yesterday was £151—unchanged from a week previous. *Copper Gossip*, the house organ of the National Brass & Copper Tube Co., a large consumer of the metal, states that the market "appears to rest on a really sound foundation," also that "conditions in this country and abroad warrant expectations of enormous consumption for years to come." It does not, however, believe that any shortage should exist under expected conditions and says that "values should be kept on a reasonable basis with the elaborate extensions completed for a maximum production."

ZINC

Producers and their representatives continue to be dissatisfied with the course of the market. They say that either zinc should be higher or that ore should be lower. They have plenty of orders on their books to keep them busy making deliveries, but they would like to be booking new business if prices were more attractive. March delivery was quoted yesterday at 10.62½ to 10.75c., St. Louis, the New York price ranging from 10.87½ to 11c. April is quoted at 10.25 to 10.37½c., and second quarter at 10 to 10.12½c., all St. Louis. Demand has been spasmodic, especially for prime Western, the brass mills having taken some special. At the same time, business in the latter has not been good, evidence of which lies in the fact that it is offered at premiums of only ½ to ¾c. over prime Western. That zinc is a good buy at present levels is indicated to some minds by the fact that dealers have been active buyers, although, on the other hand, they may be attempting to get the market going. The February exports were large, amounting to 11,030 tons. As compared with a week ago, the London quotation for spot was unchanged yesterday at £47. The quotation for sheet zinc is unchanged at 21c., f.o.b. mill, carload lots, 8% off for cash.

LEAD

The market has been quiet to the point of dullness, despite the fact that Western shipments are now coming through a little more freely. An interesting announcement of last Friday (March 2), was that of the A. S. & R. Co. advancing its quotation \$10 per ton and making the price per lb. 9c., New York. It must be remembered, however, that the leading producer sells the bulk of its lead on a monthly average basis, and that the independents already were asking far in excess of 9c. So the announcement had little effect on the market except perhaps to brace up consumers who were doubtful as to the strength of the metal. Spot lead is quoted at 10.50 to 11c., New York, with March ranging from 9.50 to 9.75c., at both New York and St. Louis. Very little business is being done in futures, and not a great deal in nearby metal. April is about 9.25 to 9.50c., St. Louis; and May, 9 to 9.25c., St. Louis. The February exports amounted to only 430 tons. The London quotation for spot, as compared with a week previous, was unchanged yesterday at £30 10s.

ANTIMONY

The spot market has been quiet, and prices are a little easier at 30 to 31c. per lb., duty paid, for Chinese and Japanese grades. Some interest has been shown in futures, mostly by dealers. March shipment from Japan is reported to have been sold yesterday at 14.75c., c.i.f., New York. Shipments from the Coast are still very backward.

ALUMINUM

No. 1 Virgin aluminum, 98 to 99% pure is a little stronger at 58 to 60c. per pound.

TUNGSTEN

There is practically no change in the market.

Mining Decisions

OIL AND GAS LEASE—CONSTRUCTION

Oil and gas lease on nineteen quarter sections held to require sinking of a well on each quarter section.

Producer's Oil Co. v. Snyder (Texas), 190 Southwestern, 514. November 25, 1916.

PRESCRIPTIVE TITLE—STATUS OF MINERAL RIGHTS

Under the law of Kentucky, where a person holding land by occupancy sells the mineral rights to another, the title of the vendee and right of possession of the minerals depends entirely upon the title of the surface occupant. If that title ripens into a good prescriptive title, it inures to the benefit of the purchaser of the mineral rights; if the surface occupant is ejected or abandons his possession before he obtains a prescriptive title, the mineral purchaser loses all his rights also.

Tennis Coal Co. v. Sackett (Kentucky), 190 Southwestern, 130. December 15, 1916.

"GRUBSTAKE" AGREEMENT—LIMITATION ON

Under a grub-stake agreement with plaintiff, a defendant made a trip to Chicago to interest capital and thence to a certain district in Sonora, Mexico, where he prospected without success. Later he made another trip to Sonora and discovered valuable mines in another district of that State. Plaintiff sued for an accounting on the theory that the defendant was a mining partner during this second trip. Held, that the grub-stake agreement related only to the first trip; that no valuable mines were discovered on that trip; and that plaintiff had no interest in the results of defendant's second trip, made at a later date to a different district.

Hollingsworth v. Tufts (Colorado), 162 Pacific, 155.

OIL LEASE—RIGHTS OF FIRST LESSEE

In a suit by a lessee of oil land to enjoin operations by the assignee of a subsequent lease, it was shown that the lessor in granting the second lease, inserted therein a clause reciting the existence of the former lease and requiring the second lessee to defend any suit thereon. Held, that this was sufficient notice to an assignee of the second lease of the rights of the first lessee, and that the mere fact that the first lessee delayed action for sixteen months and until the assignee of the second lease had expended considerable money in developing the property, would not be available as a defense to the latter party.

Mexico-Wyoming Petroleum Co. v. Valentine (Wyoming), 237 Federal, 539. October 30, 1916.

ANNUAL LABOR—TIME FOR PERFORMANCE

Plaintiff went upon his mining claims on the last day of the year in which assessment work had to be done and commenced work on each of two groups of claims; no work was done on January first, but on January second and throughout the winter, plaintiff continued in possession, working and developing his claims upon which considerable work had been previously done. On the first of January defendants went on the ground and, finding no one in possession, proceeded to re-locate the same as forfeited ground. Held, on suit by plaintiff, after reviewing authorities, that his entry and commencement of labor on the last day of the year, followed by continuous possession and work with only brief interruptions during the ensuing year was a sufficient compliance with the law requiring performance of annual labor, and that plaintiff's rights were established.

Plough v. Nelson (Utah), 16 Pacific, 1134. December 4, 1916.

Book Reviews

ELEMENTS OF MINERALOGY, CRYSTALLOGRAPHY, AND BLOWPIPE ANALYSIS. By A. J. Moses and C. L. Parsons. Pp. 631. Ill., index. D. Van Nostrand Co., New York, 1916. For sale by MINING AND SCIENTIFIC PRESS. Price, \$3.

This is the fifth edition, enlarged (200 pages more) and extensively re-written. The practical standpoint of former editions is maintained, this including a description of all common or useful minerals, their composition and occurrence, the tests necessary for their identification, the recognition and measurement of their crystal angles, and their economic importance and uses in the arts. Crystallography occupies Part I of ten chapters, of 155 pages, and clearly expounds this generally complex subject. The 52 pages on blowpipe-determinations will be found of practical value, especially those on the rarer minerals that are being sought more and more. The remainder of the book is devoted to mineralogy, detailing the physical and chemical characteristics of minerals, both common and rare. Tables give the methods for a rapid determination of the common minerals. Generally speaking, we like the arrangement followed, and find the methods up-to-date.

ENGINEERING ANALYSIS OF A MINING SHARE. By J. C. Pickering. McGraw-Hill Book Co., New York, 1917. Pp. 92. 12mo. For sale by MINING AND SCIENTIFIC PRESS. Price, \$1.50.

This is an interesting and a useful book. It would have been better if it had been edited carefully and if a wider reference had been made to other writings on the subject; but that is a good deal to ask in these days of hurried book-making. The references to exploration companies would have been more convincing if the names had been given. However, after making these minor criticisms, the reviewer is glad to commend the book as a serious and intelligent effort to analyze a recurrent problem and to explain it in a perspicuous way. The various risks involved in mining, the fundamentals of a report, the inevitably deceptive discrepancies between operating profit and real profit, and the valuing of a mine, are discussed in turn. Some of Inwood's tables are reproduced conveniently. The last chapter contains analyses of a number of important mining enterprises, and the author closes by stating that the Utah Copper is the nearest approach to a mining 'investment.' His style is pleasant, his judgment appears sound, and his whole treatment of the subject is well worthy of an experienced engineer.—T. A. R.

EDITORIAL

T. A. RICKARD, Editor

OUR contemporary *The Canadian Mining Journal* adorns its current issue with the best picture of a specimen of gold-bearing quartz that we ever remember to have seen. It is handsome and cheerful.

GOLD production in 1916 was about \$10,000,000 less than it was in 1915, according to *The Mining Magazine*. We shall discuss the subject when all the available statistics are at hand. Those from Canada have just been published, showing that 926,963 ounces of gold worth \$19,162,025 was produced in 1916, as compared with 918,056 ounces worth \$18,977,901 in 1915.

CURVES representing the cost of living threaten to run off the diagram, as we note from our reading of *The Annalist*. The curve is now sharper than that recording the increase in the gold held by the Federal Reserve Banks. The Index Number, representing the average price of 25 food-commodities, is now 233 as contrasted with 161 a year ago, and with an average of 80 in 1896.

WE publish an article on metallurgical practice at Treadwell by Mr. S. B. Combest, foreman of the cyanide plant. This will be appreciated by members of the profession as an authoritative and detailed account of the technical operations in the mills on Douglas Island now operated by the consolidated group of Alaska-Treadwell companies. Such painstaking and clear descriptions of current practice are most useful, having a value that is both timely and historical.

AMONG recent appeals to the gullibility of the public, we note the circular of the National Gold & Silver Mining Co., of Chicago, which urges the stockholders to seize "the greatest opportunity of a lifetime" in subscribing money for sinking a new shaft on their property. Funds are being raised for this purpose through the sale of more shares to these stockholders. The President of the company asserts: "The rule in mining is, that with normal volume you will get normal profits. That as you increase your volume, your profits will increase according to the square of your volume. That is, you double your normal volume, then your profits should be four times your normal profits. If you treble your volume your profits should be nine times your normal profits. The company figures that sinking the new National shaft will increase the volume of its present capacity from five to ten times. Square this increase and you can readily see that our profits will increase at least twenty-five times those of our present capacity."

This is only one more example of confusing 'rock' with 'ore'—a basic blunder. The digging of a hole in the ground, whether it be large enough to give sepulture to a dead mule or to swallow a cathedral, does not make a mine. The purpose of mining is to make money, not to hoist rock. Volume, whether normal or abnormal, bears no relation to total profit unless the unit of volume connotes a unit of profit. Judging from the character of this appeal, we infer that the mine is not making money and that the result of hoisting 25 times more rock will be an approximately equal multiplication of loss.

LAST week we stated that the American Metal Company had not exercised its option upon the excess tonnage of zinc concentrate from the Butte & Superior mill, and that the American Zinc, Lead & Smelting Company had arranged to absorb 100,000 tons of this concentrate annually. Eastern market-papers about the same time were announcing that the entire product of the Butte & Superior had been taken by the American Metal Company. Neither statement was exactly true. The American Metal at one time purchased a large tonnage, but it curtailed the amount on the outbreak of war. This company has now reverted to the earlier arrangement, but the Butte & Superior continues to smelt the larger part of its surplus tonnage at the plants of the American Zinc, Lead & Smelting Company at Caney and Dearing, in Kansas, and is at the same time selling a portion in the open market.

CONFISCATION finds sanction in law as well as in might under Carranza's régime. That is the sanctification of banditry. Manifestly the intent of the First Chief and his followers is to fatten on the re-distribution of valuable mines, with special ogling in the direction of the oilfields. This appears from the re-classification of non-metallic deposits, placing them under the jurisdiction of the Department of Fomento subject to the general mining law. Thus does Carranza exemplify the Spanish proverb of keeping one eye on the devil and the other on San Dimas. Late dispatches announce that Ambassador Fletcher has secured a promise from the Minister for Foreign Affairs that the Mexican government will not put on the screws precisely in the manner and at the time prescribed by the so-called tricolor circular No. 31, officially issued, to the consternation of mine-operators, on March 1, and dated February 21. The 'white group' comprises those who have paid their taxes and have continued operating; the 'blues' are those who have requested an extension of time for compliance with the arbitrary decree of September 14 last. Those who

see 'red' are the unfortunates that took no notice of the impossible decree of the Mexican chief. The Secretary of Fomento has accordingly turned over the list of delinquents to the Secretary of Hacienda, or Finance, as we would say, for the purpose of confiscation. It is hinted in the circular that forfeiture may possibly be averted by submitting reasons for non-fulfilment, declaring intention to resume work, and demonstrating the necessary financial ability. If the Secretary of Hacienda should then deem the reasons given and the security offered adequate in any special case, he will submit the proposals to the First Chief for consideration and recommendation. Apparently our Ambassador has received assurances based on this flimsy pretense of justice. Whatever the question of justice or privilege, it always comes back to the First Chief. He is the source of whatever dispensation from tyranny anyone may hope to receive. Rights there are none; it is an administration under which life and property are dependent on executive sufferance.

NAVAJO MINES CORPORATION is the impressive title of a new company owning sundry locations in the north-east corner of Yuma county, Arizona. The promoters of this enterprise are advertising the sale of stock as a bargain for those desirous of becoming rich easily and quickly. One of the advertisements describes the discovery of the ore by an 'old-timer,' who found a big boulder containing copper, besides "some very rich spots in gold and silver." This prospector could not ascertain the source of this big piece of 'float,' so he went up the hill, where no signs of ore were visible—"simply country-rock." This did not discourage him, however, for "he went back to the powder-house and obtained some sticks of dynamite and put in some pop-shots at regular intervals" and at once "opened up a big vein of high-grade ore, covered with only five feet of country-rock and dirt." We are told that he used only half a stick of dynamite in his pop-shooting, so that the marvel extends even to the effectiveness of the explosion; but what we want to know is how he sensed the spot for this useful performance.

Nationality in Mine-Accidents

Discrimination between immigrant and domestic labor in a Government report would savor of invidious comparison at least, the U. S. Bureau of Mines in its recent so-called technical paper entitled 'Metal-Mine Accidents,' by Mr. Albert H. Fay, makes no such distinction. At the Miami mine, however, record is kept of the nationality of the workmen involved in mishaps. The caving method is there used, which method is not, as frequently stated, excessively dangerous. According to the Bureau of Mines statistics the largest number of accidents in proportion to the number of men engaged was in overhead stoping with the aid of stulls, where the ratio of accidents was 0.51 to each miner employed. In the caving method the ratio for the entire country was 0.31 per miner. The Miami record reflects credit upon the man-

agement, since the ratio there was only 0.22 per worker. Difference in statement and detail makes a full comparison with the national figures impossible. At Miami the ratio of the total men employed during the year to the average number working at one time was 3.8, applying which we deduce that the general accident-ratio per man was 0.86. The force at Miami is strikingly cosmopolitan, 29 nationalities being represented. In the order of relative numbers Austrians come first, comprising 30.4% of the force, followed by Spaniards 16.3%, Americans 13.4%, Mexicans 13.2%, English 8.6%, thence decreasing to a stray Norwegian and Brazilian. Calculating the accident-ratio per man, dividing the number of accidents by the corresponding average number of men of each nationality working at one time, the predominant Austrian shows up unfavorably with a ratio of 0.95 compared with the evidently careful Englishman ranking nearest to immunity with a ratio of only 0.27. Regularity of attendance also speaks well for the English miner, the ratio of total number employed throughout the year to the average attendance being 1.7 in his case, against 3.1 for the Austrian. The Mexican suffered the greatest number of accidents, the ratio per man being 1.47, while his unsteadiness as a laborer is shown by an attendance ratio of 5.7. Next to the Mexican came the German with an accident ratio of 1.25, closely followed by the Italian with 1.23 per man. The American miner stands second on the list as a safe worker, the accidents per man being 0.53, but his wandering habit is revealed by the attendance ratio of 4.1. It is interesting to note that the Spaniard, second in numbers to the Austrian contingent, reveals an accident-ratio of 0.88, and in the matter of attendance he has the relatively good average of 3.8, surpassing in this respect the Americans, Mexicans, Italians, and Germans. The statistics given do not include the nature of the accident. A just comparison of relative efficiency should take into account the character of work performed. Nevertheless, the rather close correspondence between the number of accidents and the constancy of the miner in his attendance is extremely significant. The sense of responsibility is related to carefulness in the performance of duty; the steady worker is also the safe worker. This revelation, however, of the tremendous proportion of men engaged in mining who receive injuries will startle the thoughtful reader. The accident-ratio in all classes of metal mining for the United States in 1915 was 0.36 per man employed. At Miami, where race enters as a factor, the averages are not out of consonance with the general rule throughout the country. This is natural, since the mines of America are manned chiefly with foreign labor. The ratio of number of days' disability to number of workmen would plot practically a parallel curve with the accident-ratio. The Austrian had an average of 11.5 days incapacity from accident per man engaged; the Mexican 18.7, the German 16.9, the Italian 14.4, the American 6.2, and the Englishman 3.9. Racial characteristics seem to govern. It would be interesting to make efficiency comparisons as well.

The History of Flotation

The story of the flotation process is not that of a flowing stream of events, nor is it one that can be traced from a single source. Even an account necessarily as brief as the one we conclude in this issue will indicate to the reader that many cross-currents, not to say ugly snags, break the smooth surface of the record. Who, except a party to the patent vendetta, would be willing to name the first discoverer of the principle underlying flotation or the final inventor of a workable process? Was Haynes's use of oil or Bradford's surface-tension effect the pioneer invention? Neither, we think; for neither led to fruitful use. Was Carrie Everson the real forerunner? We think not, because her efforts threw ridicule on the flotation idea instead of stimulating properly qualified persons to further research. Was it Sulman? Assuredly, if any one man may be given credit, he should be chosen as the champion exponent of flotation, because he has been a student of surface-tension and allied physical phenomena longer than anybody else, and he has personally contributed to many of the important steps in the art. But a venerable voice is heard: Samuel Crowder reads a letter he wrote twenty years ago, in which he suggested using 1% or less of oil for the concentration of chalcopyrite from a quartzose ore. That letter was written to Elmore, who had devised an oil-flotation process as a sequel to the purchase of the Welsh gold mine at which Robson, four years earlier, had experimented with a similar process in collaboration with Crowder, who bought the mine from Elmore's father. Thereafter the Elmore brothers exploited their method with a success to be measured not so much by metallurgic operations as by the publicity that they gave for a decade to the new principle of concentration. They kept the flag flying, while Sulman and his partner were trying to evolve something practicable out of Cattermole's messy method of granulation. These claim to have discovered froth flotation while following this path of research, but the statement is not convincing, even if made in good faith, because in the interval they had learned how Froment used a gas to make bubbles and they had also discovered that Froment's patent was already too old to allow of duplication in the United States. Besides Froment, the Australian metallurgists, Potter and Delprat, had learned the metallurgic value of bubbles and the making of froth was well under way. We are told that suddenly, out of a clear sky, in March 1905, the spectacle of the wondrous froth of patent 835,120 was vouchsafed to the group that had banded themselves together under the name of Minerals Separation. Then the trouble began! No, not precisely then; the miraculous discovery was not made known to the American public or applied to American ore-dressing practice until six years later and was not a demonstrable success for two years more. Then came the struggle, not only to obtain a monopoly in the use of a new branch of metallurgy but the much more objectionable effort to place an embargo on technical information concerning it, backed by a malapert

attempt to tie the profession to secrecy. All this is too recent to need further recapitulation, for has it not been recorded in the pages of the MINING AND SCIENTIFIC PRESS? There remains only to make a suggestion, based on a careful reading of the voluminous records of the successive litigations, particularly the so-called demonstrations of various processes before perplexed judges, that no one man and no single group of men 'invented' or 'discovered' flotation, but that it is the cumulative result of empiricism in the mill and laboratory, rather than of patent disclosures; it is the slow product of manipulative skill on the part of a number of men most of whose names are not recorded and never will be recorded. Given the idea of pulp, oil, and mixing in the presence of air, a froth was bound to ensue that would buoy the mineral particles to the surface and so separate them from the barren particles of gangue.

Meanwhile, the forecast made in these columns more than a year ago that the function of oil had been exaggerated and that other contaminants or modifying agents would be found suitable for decreasing the superficial tension of water, and so prolonging the life of the bubbles constituting the froth, is coming true. In the Britannia mill, treating a chalcopyritic ore, less than half a pound of oil per ton of ore is being used in the flotation-cell, while at Broken Hill the use of soda-cake, instead of oil, has proved successful. As for that so-called 'critical' proportion, evolved out of the inner consciousness of patentees and their attorneys, and accepted as a scientific dictum by a misguided court of law, it has been rendered absurd within a month of the Supreme Court's solemn decision endorsing the fallacy, by the fact that large mills, each treating over 1000 tons per day, are getting good metallurgic results with 20 to 23 pounds of oil per ton of ore, a proportion that was previously assumed to kill the effective operation of the flotation machine. We are only at the beginning of flotation. The process is as much bigger metallurgically than cyanidation as cyanidation was more far-reaching than chlorination.

State Smelting

Socialization is finding a new expression. Proposals for the creation of State smelters have been made both in Colorado and Arizona. This demand is a direct outgrowth of the abnormal trade conditions produced by the War. Shipments of ore have multiplied enormously; it has been a golden era for the small producer; prospectors by the hundred all over the United States have been able to take out ore and not infrequently to make modest fortunes in the operation of mines that would possess no chance of being persistently worked with metals at usual prices. Equally have the large mines been stimulated to extraordinary production at this period when a single ton of ore is worth as much as two or three tons in ordinary times. Under such circumstances it is natural that the custom smelters should be overwhelmed. To accept and pay for all the ore that

might be flung at them, without imposing some restriction would soon empty their treasuries. Even if they could provide the capital to carry such large stocks of metal until finally sold in the Eastern market, the purchase of huge tonnages on war-inflated quotations would entail an element of risk that no intelligent body of business-men could be expected to take. We are not undertaking to argue a case for the smelters against their critics, nor to whitewash any grimy reputations. We appreciate the natural desire of the miner to take advantage of prices such as have never been seen before nor are likely to be seen again. It is proper and right that he should break into this brilliant market if he can, but the evident difficulties of the situation must be faced. In a large sense the custom smelters, by the very magnitude of their operations, and by virtue of the necessary functions they perform in our complex economic system, become in effect public servants. As such their responsibility to the people might lay them open to legislation with the give and take of special privilege and specific obligation looking to co-operation for the general welfare, on the same theory as common carriers. This might be more equitable than to confront them with a system of State-controlled competition granting that it could be made effective.

The smelters certainly should not be blamed for protecting themselves against an unsaleable accumulation of metals. The interest on the capital locked up in excessive stocks would soon absorb more than their legitimate smelting profit, or else they would be compelled to sell in quantities that would depress the market and precipitate financial disaster. This aspect of the business is so plain that no one can fail to see the motives that have led to restrictions upon the avalanche of ore that has been offered, and to the practice of discounting current quotations in effecting settlements. The position of the small shipper is equally understandable when he calls for an open market and full pay for his output. It would be most desirable to accomplish it if possible, but it is not conceivable that State-owned and operated smelters could afford the relief expected. The cost of a modern well-equipped plant capable of competing with the old established operators would prove a heavy burden; the capital necessary to carry the stocks of metal until they could be sold to advantage would amount to still greater sums. The risks due to changing market conditions would almost immediately force the adoption of measures, similar to those now employed by private smelters, in order to safeguard the State treasury. Thus the State would find itself in the end compelled to deal with the great metal-selling organizations in order to get rid of its output. There is no escape from these controlling influences. Normal competition among the great interests is what rules, whether the State or a private corporation reduces the metal from the ore. No State could finance the horde of small producers clamoring for an outlet to market. It would be compelled, sooner or later, to throw the burden back upon the shippers. If it should undertake to make settlement by the issuance of

warehouse certificates the miner would again confront the difficulties of the dominating agencies at the great market-centres. He would be under the necessity of negotiating his certificates at a discount, in the computation of which the identical factors that the private smelters are obliged to take into consideration in their dealings with individual producers would re-appear. It is well-known that small independent custom smelters invariably suffer failure. Only where the smelter has a sufficient supply of ore available from mines under its control, so as to possess a basis for operating apart from the occasional offerings of custom ore, has success been attainable. Even with these advantages the obstacle of discriminative freight-rates has always to be met, and this is hard to overcome. Within the borders of the State the rates might be subject to control, nevertheless an equitable adjustment of intra-State tariffs would not solve the whole problem; the rates on matte and bullion to seaboard markets would remain a stumbling-block, unless the independent smelter were erected at a point where large rival interests were already established, in which case the existing published rates would automatically apply. The Bunker Hill & Sullivan is a good illustration of the difficulties presented by discriminative freights. The rates on lead bullion from the East Helena smelter, of the American Smelting & Refining Company, are \$10.15 per ton to Atlantic ports and \$4.50 to Pacific terminals, equivalent to a coast-to-coast rate of \$14.65. The Bunker Hill & Sullivan was offered a transcontinental rate of \$18, applying to its smelter at Kellogg, Idaho. This has since been modified, but competitive figures so far have not been obtainable. Before proceeding toward the provision of State institutions as a remedy for private monopoly in smelting, the risks and the magnitude of the burden upon taxpayers must be recognized unflinchingly. It must be considered, also, that erratic and uncertain supplies of ore from a multitude of sources greatly increase the difficulty of maintaining effective smelting mixtures. Keeping a proper balance between base and acid becomes burdensome and costly when no large dependable resources of ore having a uniform composition are available. The operation of a custom smelter relying on a heterogeneous collection of small shipments must necessarily prove expensive, so that it would be impossible to offer rates attractive to those having important quantities of ore to offer. The inevitable graft and inefficiency that 'creep into large business controlled by political influences shout another warning. It is possible that small shippers might find the way to market easier by forming associations analogous to those that have been found helpful in marketing agricultural products. Through a single co-operative agency contracts could then be made for the delivery of important quantities of ore of known average composition. This would relieve the smelter from the annoyance of dealing with a multitude of individuals, and the dependability of such collective resources would make them attractive and worthy of consideration on more favorable terms.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Catching Floating Metallic Films

The Editor:

Sir—The discussion in a recent issue of your paper, as to the inventor or discoverer of the flotation process, brings out the fact that the process became known through the efforts of mill-men to save the metal escaping in the form of fine filmy particles floating on the water.

Every mill-man is familiar with this condition and the difficulty of arresting this loss. A few years ago I made some experiments toward saving this 'float' metal, which so far as I know have never been put into use by any one else.

Our ore was first amalgamated, then went over the tables. In the concentrate-troughs we used to notice fine lacey metal floating in considerable quantity. It was evident that the loss from this source amounted to a good deal daily. I prepared a tank with a capacity of a ton of water; bored a hole at one end of the concentrate-troughs about two inches from the top and allowed the surface-water from the troughs to pass slowly through a galvanized iron gutter into the tank. Samples were carefully taken every few minutes at the point where the water left the gutter.

It is generally known that water filtered through granulated charcoal is about as pure drinking-water as one can get. I had three tubs made, about 18 in. in diameter and 12 in. high, and placed the three tubs one over another. About an inch from the bottom of the upper tub was a 6-mesh screen. The second tub had a 10-mesh screen and the third, or bottom tub, a 20-mesh screen. On the screens was a layer of granulated charcoal. The three tubs (or screens) were placed over a bucket for catching the water as it percolated through the tubs. The water was allowed to pass slowly out of the tank into the top tub, down through the other two tubs into the bucket. *When the water entered the bucket it was pure enough to drink.* The charcoal invariably carried fully 99% of the valuable metal in the water, and on three or four occasions it assayed precisely what the water did before going into the tubs, and I have seldom found more than a trace of gold with the water in the bucket.

I wish to make it clear that these experiments have always been conducted on a small scale. At the same time the results have been so uniform that I believe they would be the same on a large scale with the right kind of apparatus and the charcoal properly prepared. There

are no difficulties in the way of recovering the values from the charcoal and the extra cost of the operation is almost negligible, as the same charcoal can be used for a considerable period of time.

GEORGE F. GOERNER.

El Paso, March 7.

The Propeller-Agitator

The Editor:

Sir—In your issue of March 3, Roscoe Wheeler, of Hedley, B. C., describes with illustrations the propeller-agitator and calls attention to your reference to the device in your article on the Nickel Plate mill. Naturally, the reader would think this ingenious pulp-stirrer something entirely new in metallurgy, but I find the following description of this propeller-agitator, baffle-board and all in the issue of the MINING AND SCIENTIFIC PRESS of September 17, 1904, page 188, where it appears under 'Concentrates':

"There are various devices for agitating pulp in the cyanide process. In some instances compressed air is employed, and has been found to be an efficient agent for this purpose. A device which has been successfully used for the agitation of sulphides in cyanide-tanks is a screw-propeller having two blades. This is keyed to a vertical shaft secured to timbers and set directly over the centre of the tank. The shaft is suspended by a collar keyed near the upper end, and held in position by passing through a box bolted to a timber about the middle of the shaft. This lower box acts like the lower guide of a stamp-stem. A pulley is fixed to the shaft either at its upper end, or between the upper and lower guides, and the agitator revolved by means of a driving belt, or it may be actuated by means of a gear, though the former is preferable. The propeller is fixed just above the surface of the pulp—silicious sands or sulphides—whatever it may be, and is submerged by the solution. When the propeller is revolved it quickly causes the pulp to be taken up and held suspended in the solution. It has been found that the rotary motion thus imparted to the pulp has a tendency to cause it to bank up around the inside periphery of the tank. This has been obviated by placing a plank on edge beneath the propeller, and extending entirely across the tank. The result is a perfect agitation with no large accumulation of pulp at any one place. In the case of sulphide treatment, the pulp being very heavy settles and packs hard almost immediately upon the stoppage of the screw, but upon re-starting it the pulp is again quickly taken into suspension. As in

the case of agitation by air, the continuous revolution of the screw is not deemed necessary. The power required is small, and the cost of the equipment not excessive. It may be run at any number of revolutions found to accomplish the desired result."

This reference to the propeller-agitator was printed 12½ years ago, and at that time evidently was not new. I do not know the date of Mr. Devereux's patent.

AN OLD SUBSCRIBER.

Misfires

The Editor:

Sir—I have read with interest the articles on the subject of misfires appearing in your publication, and will state that I have gathered hints from experiences on this score, which I may offer in discussion.

Should a charge of explosive 'misfire' the fault can lie with but four things, the fuse, the cap, the explosive, or the method of combining these to bring about the effect of blasting.

Fuse, if properly handled and not impaired by age and storage, generally burns from end to end. Few instances have been found where a defect in the powder train caused the fire thereof to go out. Detonating-caps have the twofold office of force and heat. The theory of blasting-caps is based upon the energetic explosive action of fulminate of mercury, and the force and heat are projected forward from the muzzle end of the cap. When the cap is properly crimped on the fuse, the latter serves as a plug to the muzzle end of the cap, and in view of the theory of the detonating-force of the cap the rightful and proper place for it is in the primer cartridge of dynamite at the end of said primer cartridge, that end to be placed nearest to the collar of the hole, the cap set in the outer end of the primer cartridge, parallel with its longest axis. The cap should be set in the primer cartridge about three-quarters of an inch below the muzzle end of the cap. If the dynamite used as a primer should happen to be old, it is best to cut the paper around the cartridge and break the cartridge in two, seating the cap in what was the central part of the cartridge, thus giving a chance for the initial detonation to start in an unimpaired portion.

Before inserting the fuse in the cap it should always be freshly cut, and it is good practice to cut off a half inch lest some portion of the powder-train in the fuse may have become affected through previous handling or contact with moisture. The cap should be crimped to the fuse with a crimper, making a broad crimp, not with a dull knife or the teeth. If a proper crimper is used, the joint will be watertight without waterproofing with axle-grease, tallow, white lead, soap, or other material. The fuse should be tied securely to the primer cartridge with a strong twine. It is not necessary for the fuse to be bent at an angle that will break its walls, rendering it liable by breakage to get the powder-train of the fuse damp through such break as a sharp bend will

make. It is not advisable that the fuse should burn past any part of the charge of explosive. The danger from the fuse burning past part of the charge of dynamite lies in the fact that the 'side spit' of the fuse often ignites it prematurely, when it will burn with great rapidity.

The method of lacing the fuse through the primer cartridge, and placing the cap in a slanting position therein is without justification, and is opposed to every consideration of safety and good practice. The lacing of fuse through the dynamite leads every now and then to a burned charge. The placing of the cap in a slanting position in the primer cartridge of dynamite, when it is understood that the force of the cap is exercised in a direction opposite to the muzzle, results in part of the force being directed against the side of the drill hole. The strongest caps are worth their cost as against weaker caps only when the full strength of the cap is realized; it is not advisable therefore to waste the strength of the cap by placing it in the charge so that a secondary or reflex action from the walls of the hole is produced, and that is what a slanting position of the cap in a primer brings to pass.

To aid further in safety against misfires, after the drill-hole is charged, place on top of the primer-charge a wad of paper, press down firmly with a tamping-stick, then tamp the hole firmly with clay or other material to the collar. If, then, a misfire does occur, the paper will establish a point so that the miner in digging out the tamping will know when he is close to the explosive and will proceed with due caution.

There is a current notion that if the initial detonation takes place in the middle or at the bottom of the drill-hole, the charge 'pulls' better than if the detonation commences at the end nearest the collar of the hole. There is nothing known to the manufacturers of explosives or detonators that supports this idea, and all tests indicate that the breaking efficiency of the holes so loaded that the primer is nearest the collar of the hole, will give the best results. Some may object to the trouble required with this method of charging drill-holes, but no pains are too great if it makes the life of the miner more secure, and 'safety first' should rule. The practice outlined above will reduce 90% of misfires, 'stinkers,' and deficient breakage of material blasted. It is to be remembered that this letter describes the methods that the manufacturers of fuse, caps, and explosives understand as the way in which their products should be used.

T. T. EDWARDS.

Seattle, March 3.

THE tungsten exportation from Burma in 1916, according to a United States consular circular, was 3806 tons, all of which was wolframite. The output for 1915 was 2661 tons.

A NEW COAL-FIELD has been discovered east of Harbin, in the Huton Shan mountains of China. This bed of coal is reported to be 233 ft. thick.

The History of Flotation—II

By T. A. Rickard

FROMENT

The scene shifts from Australia to Italy. At the time when Potter and Delprat introduced their methods at Broken Hill, another investigator was about to contribute his quota to the development of flotation. The Elmore bulk-oil method had been seen by Alcide Froment at the Traversella mine, in Italy, where he was engaged as an engineer in 1901, when he invented what he himself termed "a modification of what is known as the oil process of concentration." His modification—patented in June 1902—was to introduce a gas into the freely flowing oiled pulp used by Elmore. He argued, in his patent, that "if a gas of any kind is liberated in the mass the bubbles of the gas become coated with an envelope of sulphide and thus rise readily to the surface of the liquid where they form a kind of metallic magma." The phrase "gas of any kind" is important, for, although he generated his bubbles of gas by the reaction between sulphuric acid and the carbonates of the gangue or between the acid and the limestone that he added to the pulp, he hit upon one of the fundamental principles of the flotation process as we know it now. If he had specified air as the particular gas to be used he would have been acknowledged as the pioneer of present-day flotation. Air was present, of course, and played an important part in the operation, for in his description he specified the use of a centrifugal mixing device "in which two stirrers work in opposite directions, making 300 revolutions per minute." In his patent he explained that "the sulphide particles when moistened by a fatty substance" have a tendency "to unite as spherules and to float upon the surface of the water." He stated also that "the rapidity of the formation of the spherules and their ascension is in direct ratio to the quantity of gas produced in a given time." As to oil, his patent mentions "a thin layer of ordinary oil," but in the instructions given by him to the Minerals Separation people he specified as little as "1% of oil for ore containing up to 5% of metals" and up to 3½% "for ore containing 50% of metallic lead."

MINERALS SEPARATION

Before proceeding further it will be necessary to trace the origin of Minerals Separation, Ltd. At the end of 1901, John Ballot, W. W. Webster, and a Mr. Hay formed themselves into a syndicate to take an option on the Australian rights to the Elmore bulk-oil process. They engaged the firm of Sulman & Picard to act as advisory metallurgists. Acting on their advice, the syndicate did not exercise the option. In December 1902 John Ballot purchased the patents of Arthur R. Cattermole and assigned them to his syndicate, which

became known as the Cattermole Ore Concentration Syndicate. On December 31, 1903, this syndicate was succeeded by a company, called Minerals Separation, Ltd., the directors being John Ballot, J. H. Curle, W. W. Webster, S. Gregory, H. L. Sulman, and H. F. K. Picard.

Now we return to Froment. His work appears to have been unknown in England until an abstract of his British patent was published in the Journal of the Society of Chemical Industry and was seen by Mr. Sulman in August 1903. Whereupon negotiations for the purchase of Froment's patent were opened by Mr. Ballot. He went to Milan to meet Froment, who, on November 7, 1903, sold his rights for £225. On December 29 Froment sent some drawings, with descriptions and instructions explaining his mode of operation. Early in 1904 a small plant designed by him was forwarded to London, but the apparatus was discarded, and destroyed subsequently, by the Minerals Separation people. Froment was in poor health at that time, and he died soon afterward. His patents had been taken out in Great Britain and Italy, but not in the United States, and when Mr. Ballot acquired them it was too late to obtain American rights, more than a year having elapsed since the grant of the British patent, on June 9, 1902. So the Froment patent was set aside as of no immediate value.

Cattermole's patents, which had been duplicated in the United States, describe the mixing of emulsified oil with acidulated pulp, which is then agitated so as to agglomerate the metalliferous particles into 'granules' that sink and are readily separated from the lighter gangue by an up-current of water. In his American patent, No. 777,273 of September 28, 1903, Cattermole specified the proportion of oil to be used as "usually an amount of oil varying from 4% to 6% of the weight of metalliferous mineral matter present in the ore."

Much of the early experimental work of Minerals Separation was done in the laboratory of Sulman & Picard, at 44 London Wall, but in March 1904 Mr. Ballot established his own laboratory on Aldermanbury avenue, and it was there that decisive results were obtained. In 1903 a model 50-ton plant, to use the Cattermole process, was constructed and sent to the Central mine at Broken Hill, Australia.

The Minerals Separation people, notably the chief metallurgists, Messrs. Sulman & Picard, were experimenting with Cattermole's method and trying to develop a workable process at the time when their attention was called to Froment's patent. When they acquired this patent, they made experiments in accord with the specifications and the later instructions sent by Froment. To the detached spectator it would seem more

logical to assume that Froment's floating 'spherules' rather than Cattermole's sinking 'granules' would lead to something like the froth-flotation process of today. But that is not the story told in the courts of law. The metallurgists identified with Minerals Separation testify that they had discarded Froment's patent and his instructions, having found them worthless, and were trying various modifications of the Cattermole method when suddenly they happened upon the particular combination essential to the froth-agitation process. Messrs. Ballot, Sulman, and Picard agree in stating that protracted experiments were being conducted in their London laboratory under the immediate charge of Arthur H. Higgins, who had been instructed to try all sorts of variations in temperature, acidulation, oiling, and mixing. Nothing noteworthy happened until the proportion of oil was reduced, whereupon the 'granules' began to rise instead of sinking and "the quantity of floating material increased rapidly when the oil was reduced below a certain point, this certain point being 0.62% of the oleic acid on the ore." So testifies Mr. Ballot. Thus happened "the startling discovery of the agitation-froth process," according to W. H. Ballantyne, Mr. Ballot's patent lawyer. The date was March 3, 1905. Then followed the British patent No. 7803 of April 12, 1905, and the American duplicate, No. 835,120—the date of application being May 29, 1905, and the date of issue November 6, 1905.

Before leaving this part of the story it is worth noting that the Cattermole 50-ton plant, already mentioned, had been erected in the Central mill early in 1904, and experiments were made there under the direction of G. A. Chapman. Tests showed that when using 0.75% of oil on the ore "the results were excellent, with all float concentrate, no granular material being formed." So says James Hebbard, the manager of the Central mine.¹¹ The adjective "excellent" is used in the light of later events, for floating of the mineral was incompatible with the granulation upon which the Cattermole process depended. The importance of the floating does not seem to have been appreciated until a year later—early in 1905—when "a remarkable development in the operation was discovered (strangely enough, at the same time here [Central mine] and in the Patent Co.'s [Minerals Separation] laboratory in London), which had for its main principle the reversal of all previous operations, and consisted in the complete flotation of each particle of mineral independently in place of granulating the mineral particles and causing them to sink, thus not only revolutionizing the process, but greatly simplifying and cheapening it. The

¹¹Proceedings Aust. Inst. of M. E., November 10, 1913. The same engineer relates how, before 1901, "it had been long observed that a froth was formed containing high metallic values, in silver and lead particularly, whenever conditions were favorable, as for instance, where the rotation of trommels, or the splash of the elevators or raff-wheels, or the motion of the jig-plungers, produced a violent agitation of the mill-water containing slime." The use of oil tended to make such froth more persistent. I have mentioned the suggestion made by Beauchamp and Shellshear in 1902 while at work in this same mill.

developments noted were mainly along the line of decreased consumption of oleic acid, for example, from 3% oleic on ore, resulting in very little float, down to 1%,¹² giving practically a complete float." According to this, the Higgins 'discovery' was made independently and contemporaneously at Broken Hill, but the underlying principle was detected a year earlier by Mr. Chapman, who had experimented with the Froment process in the London laboratory of Minerals Separation during 1903—again the suggestion that Froment had pointed the way to the agitation-froth process.

Next we revert to the first contact between the Elmore brothers and the Minerals Separation people. As already mentioned, in 1901 the Ore Concentration Syndicate gave Messrs. Ballot, Webster, and Hay an option on the Australian rights to the Elmore bulk-oil process. In accordance with this agreement, Mr. Ballot and his associates sent ore to be tested at the Elmore laboratory, to which they had free access while the experimentation was in progress. In the agreement it was stipulated that the holders of the option "and their assigns" should notify the Elmore syndicate of any "improvement, addition, or discovery" that they might make and the Elmore syndicate was "to be entitled to every such improvement, addition, or discovery whether the same shall be patented or not."

Mr. Ballot and his associates made tests and held the option for 11 months, that is, until late in 1902. Messrs. Sulman and Picard were engaged by Mr. Ballot to supervise the tests. They were "treated with the greatest frankness," says Stanley Elmore. The option was not exercised. Then followed Mr. Ballot's purchase of the Cattermole patents and in the succeeding year the acquisition of the Froment and Sulman & Picard patents, followed immediately by the organization of Minerals Separation, Ltd., as a process-exploiting company. In 1905 the Elmores brought suit to enforce the clause above quoted, in the agreement of 1901, claiming that they were entitled to the benefit of the improvements following upon the insight into the process given to the Minerals Separation people during the tests made under the option. The case went against the Elmores, the Court of first resort deciding that the particular clause had been introduced into the contract without sufficient authority after it had been signed. In the second trial, Messrs. Ballot, Hay, and Webster presented evidence to show that the Cattermole and other patents had never been in their possession but had passed from the inventors through a trustee to the syndicate that became Minerals Separation, Ltd. Whereupon the proceedings were stayed. The affair left a feeling of bitter animosity between the two factions; the Elmores showed so keen a sense of betrayal as to resign from the Institution of Mining and Metallurgy when Mr. Sulman was nominated for the presidency of that professional society in 1911. This incident indicates the bitterness, rather than the merits of the quarrel, but it must be recorded in this history of the process because it helps to explain the

¹²Not below 1%, apparently.

acerbity of the litigation that ensued and that still animates the protagonists in this metallurgical vendetta.

For three years, from 1906 to 1909, the Elmore's fought Minerals Separation's attempt to hold a patent in Germany. The patent was granted, but it was annulled subsequently by a higher court.

In 1907 Minerals Separation brought suit against the Ore Concentration Company, alleging infringement of Froment's patent, but in 1909 the Minerals Separation company discontinued the action, paying costs.

In 1909 the Elmore's and the British Ore Concentration Syndicate brought suit against Minerals Separation for infringement of Frank Elmore's bulk-oil patent of 1898 and Stanley Elmore's patent of 1901, specifying the use of acid in the bulk-oil process. They lost in the first court, they won on appeal, but lost on final resort to the House of Lords. Both the use of oil and of acid were held to have been anticipated, and the Minerals Separation froth-agitation process was held to be entirely different from the bulk-oil method. Subsequently a new suit was started in Australia, the claim of infringement against the Sulphide Corporation, a licensee of Minerals Separation, being based on acidulation. The Australian court decided against the Elmore's, who appealed, unsuccessfully, to the Privy Council, in 1914.

AIR-AGITATION METHODS

It is important to note that these suits dealt only with the bulk-oil patents of 1898 and 1901, and had no reference to the vacuum process of 1904. To the agency of gas in flotation we now return. So far the fact that bubbles of air would do the work of bubbles of chemically generated gases had been overlooked. In September 1903, Sulman & Picard described the use of air "or other gas" in British patent No. 20,419, which was duplicated in the United States as No. 793,808. In this they pictured a perforated coil of pipe through which either air is introduced into pulp with which oil has been already mixed or air and oil are admitted simultaneously in the form of a spray. The latter scheme has not proved practicable, whereas the procedure in which the oil is previously mixed with the pulp and then subjected to aeration by the introduction of air through the perforations in the pipe is a practical method. They said: "The oiled metalliferous particles resulting from either of the processes above described have the power of attracting to themselves, with a greater comparative strength than the gangue particles, the films or bubbles of gas which exist in the mass and are thus raised to the surface of the liquor by gaseous flotation." They did not claim the use of air as a discovery and they seem not to have known how near they were to the later phase of flotation, in which the making of a multiplicity of air-bubbles, or 'froth,' is the principal feature.

In June 1904 Frank Elmore applied for a patent to use electrolysis in order to generate gas in a freely flowing pulp, and in August of the same year he obtained British patent No. 17,816, in which he described the performance of flotation in a vacuum, so as to liberate "the

air or gases in the milling water." Thus six years after the date of his first bulk-oil patent Elmore had learned to put the air to purposeful use. He subjected the oiled and acidulated pulp to a vacuum, thereby releasing the 2.2% of air normally absorbed in water. By lowering the pressure and raising the temperature this air is released, thereupon attaching itself, in the form of bubbles, to the oiled sulphide particles, which rise to the surface. For example, the air in a ton of pulp consisting of 6 parts of water to 1 of ore suffices to lift 360 pounds of zinc-lead sulphides in a Broken Hill ore. In actual practice, however, the weight of sulphides floated is considerably greater than the theoretical proportion as based on the efficacy of the air released from absorption in water. Part of the work is done by the gaseous carbon dioxide liberated by the reaction between the acid and the carbonates, such as calcite, either in the gangue or added in the form of limestone. But a larger part of the bubbling is caused by the air entangled in the ore particles and entrained in the pulp during energetic mixing. In this process the quantity of oil added to the pulp was reduced from the ton used at Glasdir to 10 pounds per ton of ore, and finally to as little as 3 pounds per ton of ore. The machine devised by Mr. Elmore for the performance of his vacuum process was remarkably ingenious and to it the success of the process was largely due. It was applied at several Scandinavian copper mines, notably the Sulitelma, and also in the Zinc Corporation's mill at Broken Hill, as already mentioned.

This vacuum method of Elmore was a notable step toward the recognition of the part played by air in flotation, and insofar as he used air in a pulp that had undergone agitation with a relatively small proportion of oil he furnished a metallurgic sign-post that pointed to the final success of the process.

FLOTATION IN AMERICA

So far flotation had received scant attention in the United States. The old Elmore bulk-oil method had been tried, unsuccessfully, at the Boston Consolidated and Mammoth mines in Utah in 1900 and 1901. In 1906 a surface-tension process of great ingenuity, invented by A. P. S. Macquisten, was used in the Adelaide mill, at Golconda, Nevada, and in 1911 a similar plant was erected at the Morning mine, in Idaho, but these interesting efforts were mere ripples on the calm surface of American apathy, which at the time gave no promise of the full tide of metallurgical advance that since then has swept over base-metal mining in the West.

Another American patent must be mentioned, as linking the Elmore bulk-oil process with the later frothing methods. The patent of Edmund B. Kirby is No. 809,959 of December 14, 1903. He used from 25 to 75% of oil in a flowing pulp; but he depended upon thin oil—kerosene—and violent agitation, so that he departed from the Elmore type of flotation. The more interesting feature of his claim, however, is "the injection of a gas, preferably air, into the mass," which statement, if taken with his reference to "allowing the hydrocarbon-coated

particles to float to the surface of the mass," seems indeed to be a forecast of froth-flotation. The patentee—Kirby—himself says: "It is thought that the use of a gas to assist in the flotation of the coated particles * * * is radically new in this art." He adds: "The employment of the gas in the manner stated brings in a more powerful floating agency than anything before used." How prophetic! His gas was "preferably air." Moreover, he knew of the use to be made of the air "dissolved" in water, as adopted a year later by Francis E. Elmore, for he says: "The air-bubbles not only tend to attach themselves directly to the coated particles, and thus float them to the surface, but the air becomes dissolved in the water to its maximum capacity. This dissolved air tends to again separate itself from the water and attach itself in minute globules to the coated particles." He used 'dissolved' as Elmore did, as an equivalent for 'absorbed,' for the air in water has not undergone solution. Mr. Kirby tried his process on a number of British Columbian ores, but no working plant was erected; nevertheless, it is apparent that he has not received proper credit hitherto for his ingenuity, and it is a pleasure to make the correction here.

The credit for bringing the froth process to the notice of the American public belongs to J. M. Hyde, who had been in the employ of a subsidiary syndicate organized by Minerals Separation for the exploitation of flotation in Mexico. Mr. Hyde was introduced to Mr. Ballot by Theodore J. Hoover, who, in October 1906, had been engaged by Mr. Ballot as technical adviser and general manager for the Minerals Separation company. In 1910 Mr. Hyde went to Mexico and early in 1911 he resigned, at the conclusion of his one-year contract with the syndicate. Shortly afterward he went to Montana, at the instance of H. C. Hoover, to inspect the property of the Butte & Superior Copper Co., this company having offered Mr. Hoover a participation in a bond issue. The business proving unattractive, Mr. Hoover withdrew from it, but Mr. Hyde commenced to investigate the metallurgical problem presented by the zinc-lead ore of the Butte & Superior company's Black Rock mine. After making the necessary tests with the slide machine, he erected a trial plant in disregard of the Minerals Separation patents. This was in August 1911, and not until the Butte & Superior company had negotiated with E. H. Nutter, the American manager for Minerals Separation, who demanded a prohibitive royalty. In October 1911 suit for infringement of patent was brought by Minerals Separation against Mr. Hyde.

Meanwhile, in December 1910, T. J. Hoover had severed his connection with Minerals Separation, after having been instrumental in the successful development of the company's business in Australia and in improving the various apparatus employed in the froth-flotation process, especially in that country. His resignation was accompanied by some friction with Mr. Ballot, into the details of which it is not necessary to go, but the fact is a part of the history of the process. In December 1912 Mr. Hoover published his book, 'Concentrating Ores by

Flotation,' after a grudging consent had been obtained from his former employers, in return for which he excised parts of the original manuscript trenching too deeply into patent matters. This is recorded here in order to remove the impression, still persisting, that Mr. Hoover wrote and published his book while connected with Minerals Separation.¹⁴

We now return to Mr. Hyde and the commencement of a big litigation. The suit started against him in 1911 was tried first in the District Court of Montana and judgment was given against him in August 1913. On appeal, before the U. S. Circuit Court of San Francisco, this judgment was reversed in May 1914. By writ of certiorari the case was brought before the Supreme Court of the United States, which on December 11, 1916, reversed the decision of the Appellate Court and decreed that patent 835,120 was valid, but confined the scope of the patent to violent mechanical agitation, the use of less than 1% of oil, and a persistent kind of froth.

It is worthy of note that the first successful froth-flotation plant erected in the United States, by Mr. Hyde in 1911, did not start until six years after the grant of patent 835,120 and not until 20% of the world's production of zinc was being made by aid of the group of other flotation processes in use at Broken Hill. This may be compared with the statement of the U. S. Supreme Court, in its final review of the Hyde case, that "the process in suit promptly came into extensive use for the concentration of ores in most, if not all, of the principal mining countries of the world, notably in the United States."

The first successful application of the froth-flotation process in the United States was made at Butte, on a zinc-lead ore, as we have seen. The later development of the process has been based on the treatment of copper ores, especially the chalcocite disseminated in the immense ore-bodies disclosed in Arizona, Utah, and Nevada. This part of the story begins with the tests made by Minerals Separation in their London laboratory and in plants erected at sundry copper mines in other countries, such as the Caucasus Copper and the Great Fitzroy, with results generally poor. In his book, dated July 4, 1912, Mr. Hoover refers to the limitations of the process and says:¹⁵ "The fourth limitation is one for which at present no adequate reason can be given. An ore in which the valuable minerals are wholly or partly bornite or chalcocite, as those of Bingham canyon, will probably give trouble to flotation processes, although not always. For among the many ores tested the one which gave the most uniformly satisfactory results was a copper ore assaying 2.8% copper, all in the form of microscopic specks of bornite." He proceeds to remark: "It may be that only those ores where bornite and chalcocite are of secondary occurrence give trouble." In Mr. Hyde's

¹⁴In mentioning these and other personal incidents, like the Elmore-Sulman & Picard affair, I am prompted solely by the desire to state facts essential to a correct understanding of the conditions governing the patent litigation, because they played a decisive part in the technical development of the process.

¹⁵'Concentrating Ores by Flotation,' first edition, page 157.

report of January 8, 1911, given as an exhibit in the lawsuit, it is stated that the tests carried out in the Minerals Separation laboratory proved that "the copper ores of a good part of the Southwest and also of at least a portion of the Utah region contain chalcocite, *which is not floatable by any of the methods so far tested.*" This summarizes the opinion held by the Minerals Separation staff at that time. However, they discovered their mistake two years later. Tests on chalcocite ore from the Inspiration mine, in Arizona, were made in Mr. Nutter's laboratory at San Francisco during 1912, but the results were not good enough. At the end of that year, however, an 87% recovery on a 2% copper ore was obtained in a 15% concentrate. The telegram sent to the New York office of the company was mutilated in transit so as to state that a 50% concentrate had been obtained, and premature rejoicing followed.¹⁶ Nevertheless the Minerals Separation staff promised good results and erected a 50-ton experimental plant at the Inspiration mine. The company took out a license early in 1913. On March 23 an experiment on low-grade chalcocite ore was made by T. A. Janney at the Arthur mill of the Utah Copper Company. This proved satisfactory. During that same month, March 1913, the Minerals Separation staff, at the Inspiration mine, had demonstrated a 90 to 92% recovery and a 35 to 40% concentrate on a 2% ore, with a 0.15 to 0.2% tailing. The presence of a colloidal kaolinized mineral diverted the oil from its proper function and interfered with the recovery of copper until G. A. Chapman suggested the addition of the oil to the ore in the tube-mill, where the metallic particles became oiled at the instant of exposing fresh fractures. These experiments warranted the expectation that on a 1.58% ore there would be obtained a 27½% concentrate with a recovery of 92% and a tailing loss of only 0.13%. A 600-ton Minerals Separation test-plant was erected in January 1914; in July of that year a pneumatic equipment consisting of five Callow cells and one Pachuca tank was added; and between August and October a Towne machine was in use. In 1915 the Inspiration Consolidated Copper Co. built a mill of 18 sections, each of 800 tons capacity, or a total of 14,400 tons daily. Since then this mill has treated as much as 21,000 tons in a day.

In June 1914 Mr. Chapman started flotation experiments at Anaconda in a 200-ton plant, obtaining 90% recovery. On February 1, 1915, the Anaconda and Inspiration companies signed a contract with Minerals Separation by the terms of which they agreed to pay royalty on a sliding scale ranging from 12 cents per ton on 4000 tons daily to 4 cents per ton on the treatment of more than 30,000 tons daily. By a curious proviso in the contract no royalty was payable on the 5000 tons between 10,000 and 15,000 tons daily. The tonnage coming under the terms of this agreement included the ore treated by sundry subsidiary companies, the consequence being that the maximum tonnage and minimum royalties specified in the agreement were reached by the

close of 1916 at which time the Anaconda flotation plant was treating 14,400 tons daily. As an example of the saving made by aid of flotation, it is worth mentioning that whereas the tailing from the water-concentration mill used to assay 0.62% copper, the residue now after treatment in the flotation annex assays only 0.15% on a 3% ore; that is, out of 60 pounds of copper per ton only 3 pounds goes to waste, as compared with 12.4 pounds formerly. The recovery is 95%. Moreover, the metallurgical improvements made at the Washoe plant during 1915 were so effective as to enable an increase of 55,000,000 pounds per annum to be made in the production of the Anaconda company "without increasing the tonnage or grade of ore that has been mined in the past." So testified Mr. John D. Ryan, the president of the company in his annual report.¹⁷ Further, he stated that "approximately 40,000,000 pounds of this increased production will be made without adding to the cost per ton of ore treated." This is the equivalent of the output from a big mine.

Meanwhile preliminary tests had been started at the Miami mine, which is a near neighbor of the Inspiration. From December 1913 to August 1914 the testing was directed by R. C. Canby, who used various types of apparatus, notably the Minerals Separation and Towne machines. On August 7, 1914, a pneumatic flotation plant was erected. The remodeled mill, having a capacity of 4200 tons, went to work on March 15, 1915. On July 14, 1914, Minerals Separation brought two separate suits based on patents 835,120 and 962,678, but these suits were dismissed on request of Minerals Separation, and on October 10, 1914, a single suit was started for infringement of three patents, the two already mentioned and No. 1,099,699.

Instead of using the blade-impeller type of agitator, the Miami Copper Company adopted the Callow machine, essentially a sloping launder with a canvas bottom through the pores of which air under small pressure is admitted into the pulp previously oiled. Such oiling of the pulp was aided at first by the use of a Pachuca tank, but in the spring of 1915 this type of agitator was found superfluous and since then the oil has been simply added to the pulp while flowing through a launder to the flotation-cell. In the trial of the suit before the District Court of Delaware, the defendant claimed that he was not using the agitation-froth process of patent 835,120 but a bubble method similar to that of patent 793,808, which was granted to Sulman & Picard on July 4, 1905, on an application dated October 5, 1903. In this patent a perforated coil of pipe is described, the idea being to admit air and oil in the form of spray, so that the globules of oil attach themselves to the metallic particles in the ore and float them to the surface. The pneumatic machine used at Miami was devised by J. M. Callow and patented as No. 1,104,755 of July 21, 1914. The idea had been used already in T. J. Hoover's British patent No. 10,929 of 1910. Mr. Hoover's patent was not duplicated in the United States and Mr. Callow was:

¹⁶M. & S. P., March 18, 1916.

¹⁷M. & S. P., February 26, 1916.

unaware of it. Another investigator, R. S. Towne, had patented the idea previously, in the form of a carborundum wheel, the central hole of which he plugged, so that the wheel served as a porous bottom. The admission of air to make froth, without the aid of mechanical agitation, was developed in several machines at a later date—in 1915 and 1916—as has been duly recorded in the technical press.¹⁸ The kind of froth produced by blowing bubbles of air through the pulp is claimed to be different from that made by beating air into the pulp with a mechanical stirrer; in the one case the froth is said to be thin, tender, and evanescent while in the other the froth is described as thick, coherent, and persistent.

However, the first trial-court decided in favor of Minerals Separation's contention that the Miami Copper Company was infringing its patent, 835,120, and also 962,678. The judgment was delivered on September 30, 1916, an appeal being filed at once by the defendant.

Patent No. 962,678 is important and interesting because it involves an idea to which no reference has as yet been made in this brief history of the process: I refer to the varying solubility of oils and the use of soluble agents for that modification of the surface tension of water to which the phenomena of froth-flotation or bubble-levitation are so largely due. The idea is not recent. Haynes, in his British patent of 1860, used coal-tar from gas-works in a rudimentary process of oil-flotation. Coal-tar contains as much as 20% soluble products. In U. S. patent 788,247, dated April 25, 1905, Cattermole, Sulman, and Picard used cresol and phenol, both soluble in water, as modifying agents.

On June 29, 1910, Sulman & Picard obtained U. S. patent 962,678 for a 'soluble frothing agent,' and this is the patent that the Miami company is charged with having infringed by reason of using cresol with pine-oil in its flotation operations. Application for this patent was filed on April 30, 1909. The illustration shows a beater form of agitator and "beating air into the mixture" is specified. Mention is made of "an organic compound in solution" and "amyl acetate" is instanced. No particular proportion of this "mineral frothing agent" is specified and an increase of the soluble substance is held not to interfere with the operation. The decision of the higher court on the validity of this patent will have an important bearing on the future of the flotation process, for it is manifest that the term 'soluble frothing agent' is extremely comprehensive and will frustrate legitimate attempts to avoid the embargo on the use of oil. Meanwhile the Supreme Court's recent decision validating the patent on the use of a 'critical' proportion of oil, namely less than 1%, has been stultified by successful concentration on a scale of 1000 tons or more per day

when using 22 to 23 pounds of oil per ton of ore. At the same time comes the news of the Freeman process, in which soda-cake is being used successfully at Broken Hill as a modifying agent instead of oil. The litigation is far from ended and before it is closed it will be likely that oil will have been discarded in favor of other contaminants capable of lowering the surficial tension of water so as to permit the formation of a metallurgic froth.

In 1914 the flotation of oxidized lead ores became the subject of successful experiment, the method being to sulphidize the exterior of the oxides by means of sodium sulphide. This was accomplished so successfully that an effort was made in 1915 to apply the method to oxidized copper ores, which, however, are not readily amenable because the sulphidization penetrates the ore-particles so deeply as to interfere with the differential treatment and to consume an excessive amount of the sulphidizing agent. The treatment of zinc-carbonate ores by sulphide-filming has been even less successful, owing to the fact that such ores contain enough zinc silicate to interfere with flotation.

The story of flotation flows by devious ways and is broken by many cross-currents. Patents serve to record the high-water marks of ingenuity but they fail to disclose the movement between given points, and, what is much more important, they ignore the slow increase of manipulative skill. It is to manipulation, learned empirically in the laboratory and mill, that the flotation process owes its metallurgic success. Given the directions to be found in Kirby's or Froment's patents, the flotation expert of today can produce an effective result, without, apparently, borrowing from any later inventor. That is why the experiments made in Court have proved almost anything it was desired to prove. The manipulation to which success in the mill is largely due contravenes no patent and trespasses no man's preserves. A proof of this is to be found not only in the slow application of the flotation idea in metallurgy but in the delay that marked the fruitful use of the latest phase of the process. The froth-flotation that is claimed to be a new discovery is said to have been discovered in 1905; yet it was not introduced into an American mill until 1911, and even after that event the most skilful engineers, whether in the employ of the patent-mongering company or not, failed to apply it successfully for several years, not until 1914.

Haynes and Bradford left no trail. Everson failed to arrive, but it is likely that her patent put the idea of flotation into the heads of others, for example, Robson. He did not succeed, but he gave the clue to Elmore, who then prompted Froment and Kirby. Sulman was experimenting with the Cattermole method when he heard of Froment's scheme, and from that, I believe, he got the notion of using air to make a froth. Hoover, Callow, and other technicians, by the patient empiricism of the mill and laboratory, developed a workable process. Such, in brief, I believe to be the true pedigree of the flotation process.

Electrical Precipitation in Metallurgical Plants

By R. W. Kerns

***INTRODUCTION.** When a gas is in an ionized condition and passes an electro-static field its ions begin to travel at a high velocity in the direction of one or the other of the electrodes causing the field. If the electrodes are charged to a high potential they become the ionizing agents as well as the source of the propelling force. These highly charged ions are continually bombarding any solid particle that may be in the field and impart a charge of like potential to the particle, which in turn begins to travel toward the electrode of opposite polarity. If one of the electrodes is a sharp point or a small wire, a greater stress is set up, resulting in greater ionization from this electrode only. Thus the gas receives a static charge of this same polarity. A striking illustration of the ionization due to points is shown by the old experiment of blowing out a candle by means of a highly charged needle.

Practical advantage is taken of these principles in electrical precipitation. The gases to be treated are caused to traverse metallic tubes at a velocity not greater than 12 ft. per second. Each of these tubes becomes an electrode, while the other electrode is formed by a fine wire stretched along its central axis. A uni-directional potential of from 25,000 to 250,000 volts is applied, charging the solid or liquid particles in the gas and causing them to be deposited on the inner surface of the tube. The dust is collected at intervals by vibrating the tubes and thus shaking the dust into bins. At these times both the current and the gases are shut off from the section of tubes being cleaned.

HISTORICAL. That dust suspended in gases could be removed by electrical discharge was suggested nearly a century ago. In more recent years Sir Oliver Lodge rediscovered the same phenomenon and suggested its application to purifying the atmosphere and eliminating soot or other objectionable matter from smoke. The first attempt to use the principle commercially was made at the Dee Bank lead works in 1885. Wimshurst influence-machines were used as the source of electrical energy. These machines lacked the requisite capacity and stability of potential, and hence the first patents were allowed to expire without successful use. Twenty years later Lodge again revived interest in the subject by patenting the use of the new mercury-arc rectifier as applied to the electrical precipitation of suspended particles. It remained, however, for F. G. Cottrell, of the University of California, further to develop the process. Following extensive laboratory experiments, he succeeded in having his invention installed in the DuPont Powder Co.'s plant at San Francisco for precipitating sulphuric acid

mists. The process was soon after adopted by the Selby Smelting & Lead Co., at San Francisco, whose chimney-gases had become a nuisance because they contained so much sulphuric acid, arsenic, and lead salts.

Preliminary experimentation was necessary at both of these places and many disappointments and obstacles were met and overcome before these plants were operat-

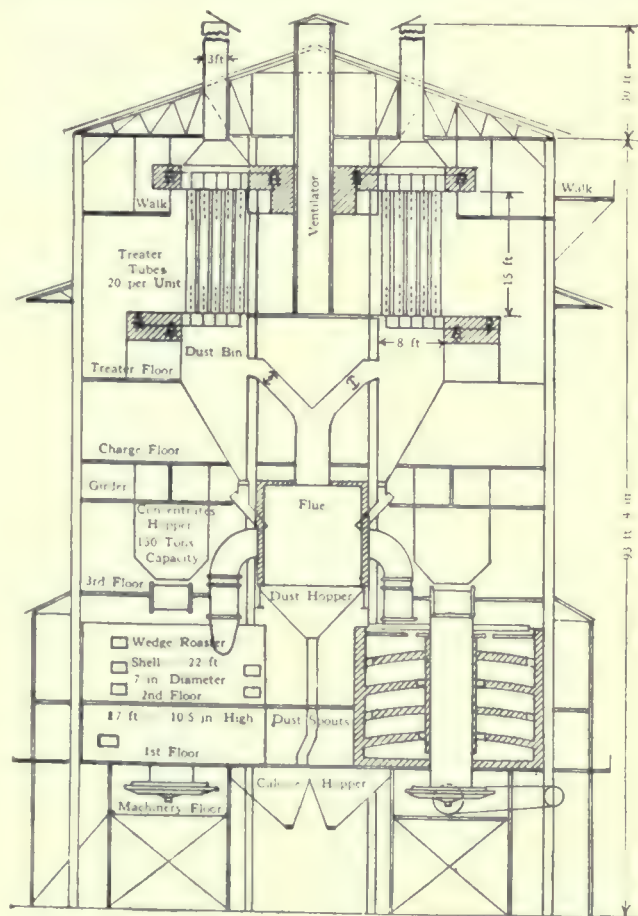

FIG. 1. PRECIPITATION PLANT OF THE INTERNATIONAL SMELTING COMPANY.

ing successfully. Electrical precipitation is now used or being installed at the following plants: Washoe smelter, Anaconda; Garfield smelter, Garfield; Raritan refinery, Perth Amboy; Omaha smelter, Omaha; Goldschmidt Detinning Co., Chicago; International smelter, Tooele; and the Trail smelter in British Columbia. At most of these plants the recovery of copper, gold, silver, or lead is sought. At Anaconda electrical precipitation is used to collect white arsenic. Two treaters in series are used and the dust is separated from the arsenic by fractional precipitation. The gases enter the first treater hot and the dust is collected. By admission of air the gases are then cooled from 310 to 90° C., and in the second heater pure white arsenic is collected. Fractional precipitation thus

*Abstracted from *The Electric Journal*, to which we are also indebted for the illustrations.

renders the refining furnace unnecessary. At Anaconda another large installation is also being made to handle the gases from the roasters.

At the Bureau of Mines station at Pittsburg an interesting plant is used to precipitate soot from boiler-gases. One of the earliest plants was built by the Riverside Portland Cement Co., in California, where 900,000 cu. ft. of gas per minute is being treated and about 90 tons of cement-dust precipitated per day. The wide application of the process is also shown by a recent installation for the precipitation of powdered food, such as powdered milk or cream and powdered eggs; also in the removal of tar from illuminating gas and recovering chlorine in bleaching-powder works.

At MIAMI. Two precipitation plants are installed at this smelter, one of which treats the gases from the roasting or drying furnaces and the other treats the converter-flue gases. The main object of both of these equipments is to recover the copper that would be lost if these gases were discharged directly into the atmosphere. At most modern copper plants this saving has been accomplished by building enlargements in the flue, or large dust-settling chambers. But experience has demonstrated that a more complete recovery may be obtained by electrostatic precipitation.

A cross-section through the roasting-plant is shown in Fig. 1. The precipitation apparatus is mounted over the drying-furnaces and is provided with 12 chimneys, 30 in. diam. by 30 ft. high, for discharging the treated gases into the air. This arrangement was chosen over the alternative scheme of bringing the gases down to treaters on the ground-level. A single chimney conducts the treated gases away and provides draft.

The electrode-tubes are 13-in. welded-steel pipes 15 ft. long. They are belled outward at each end to reduce the brush-discharge at these points. Twenty of these tubes, together with other accessories, make up a unit, which has its own gas-intake, chimney, and electrical connections. The gas can be shut off from one of these units by means of dampers, the switches opened and the tubes vibrated by means of mechanical hammers to shake the collected dust into a hopper beneath. Twelve such units comprise this plant.

The other and ungrounded electrode is a No. 20 nickel-chrome-steel alloy wire. A light steel frame, supported on insulators, enters the hood through glass windows. One such frame is used at the top to support the electrode-wires, which are spaced at the bottom by a similar frame. A five-pound weight at the bottom of each wire holds it taut.

The gas consists almost entirely of air with a high percentage of water-vapor and carbon di-oxide, at a temperature of about 80° C. The gas also is permeated with a fine dust carrying about 25% copper. About five tons of this dust is collected per day. The efficiency obtained is practically 100%; no visible material can be seen escaping from the exit-stacks under normal operation.

No trouble is experienced in the operation of this plant, provided a temperature is maintained sufficiently

high to prevent the condensation of moisture in the tubes. Such moisture would not only make the precipitate a sticky mud, which would be difficult to dispose of, but, together with any sulphur tri-oxide that is certain to be

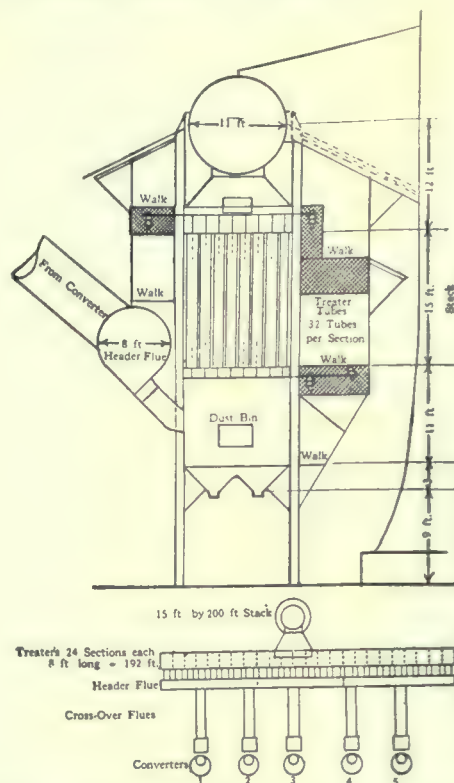

FIG. 2. PRECIPITATION PLANT AT MIAMI, ARIZONA.

present in small quantity, would hasten the destruction of the treater itself by corrosion.

CONVERTER-PLANT. This gas differs from the roaster-gas by having the higher temperature of about 200° C. and by being dry and containing a large percentage of SO_2 and SO_3 . In order to treat the larger volume of gas

FIG. 3. ELECTRICAL CONNECTIONS OF APPARATUS.

the units were made to include 32 thirteen-inch tubes each. The five converters deliver their gases to one common header-flue. The 24 units of the precipitation plant draw their gas from this flue and discharge upward into another common header, which leads to a 15 by 200-ft. chimney. As in the dryer-plant, the collected dust is shaken down into bins placed over standard-gauge tracks. A covered and dust-tight lorry-car transports the dust directly over the reverberatory charge-hoppers, through

which the dust passes into the furnaces. The velocity of the gas is six feet per second, based on a total volume of 250,000 cu. ft. per minute.

The principal change made in the treaters since the original installation has been the housing in of the treater-units with corrugated iron placed about each set of tubes. The reasons for doing this were three-fold: First, it was found that the wind chilled the tubes on one side, which caused most of the gases to pass up the tubes on the other side of the treater. This unequal distribution of gas is cumulative, the hot tubes becoming still hotter owing to the large volume of hot gases going through them, while the cold ones soon cooled off entirely and took no gas at all. This effect is being avoided in the latest installations by adopting down-draft tubes, in which this effect of chilled tubes is self-corrective instead of being cumulative. Second, the chilling of the dryer-gas condensed moisture and sulphuric acid on the tubes, as referred to above, is entirely obviated by housing them in. Third, in the converter-plant the maximum

of draft is desirable and can be obtained only by keeping the gas entering the main stack as hot as possible.

ELECTRICAL APPARATUS. In order to obtain a uni-directional current at from 60,000 to 100,000 volts, a rotary switch is used to rectify the current of a high-potential transformer. Two arms carrying a segment of copper plate at each end are mounted on a shaft at right angles to each other, as in Fig. 3. The arms are insulated from the shaft and from each other and revolve between the adjustable brushes, which clear the plates by a half-inch. Electrical synchronism is obtained by driving an alternating-current generator directly connected to the switch. This generator furnishes the primary current of the transformer as well as the means of voltage-control by variation of field-resistance. The generators and transformers each have a capacity of 15 kva. There are eight of these electrical sets operating at about two-thirds capacity, besides two spare units. This means a power consumption of 16 watts-seconds per cubic foot of gas treated.

Metallurgy at Cobalt in 1916

*The outstanding development in the metallurgy at Cobalt in 1916 was the increased use of flotation. Plants are now in operation or in construction at the Buffalo, McKinley-Darragh, Dominion Reduction, Coniagas, Beaver, Trethewey, Northern Customs Concentrator, National, and Nipissing mines.

The Buffalo has the largest plant, rated at 600 tons per day. The large pile of concentrator tailing will be re-ground in tube-mills and treated by flotation, along with the regular output of the mine. For the most part, flotation is confined to the treatment of the fine material that formerly went to the slime-tables. This material, assaying about 6 to 8 oz. silver, yielded poor extraction on slime-tables, but by the new process it can be reduced to 1 to 2 oz. The equipment for floating the regular concentrator-slime is cheap, and the feed comparatively rich. The next step will be more costly, that is, the re-crushing of the sand-table tailing in tube-mills, followed by flotation. The feed will average about 3 oz. silver. The profit on this will, therefore, be less.

The Callow pneumatic cell is used generally throughout the district. Machines of the impeller type have not been thoroughly tried, though several Groch machines are working. The Kraut-Kollberg machine has also been used. The Callow cell has acquired many new details in Cobalt practice. Transverse baffles reaching to within two or three inches of the bottom prevent surging. In several mills the froth is allowed to overflow only at the tailing end of the cell; in another the froth collects at four different levels in the cell and cascades over the baffles from one compartment to the next, overflowing at the feed end. These two devices raise the grade of the concentrate on this ore. Whether they will result in a higher tailing remains to be seen.

The flotation of the residue after cyanide treatment has been the subject of a great deal of experimenting at the Nipissing, but the result is still far from satisfactory. It was thought that the presence of 0.04% cyanide and 0.03% alkali in the pulp solution was the cause of the poor extraction. This was remedied with acid, but results were no better. The most likely explanation is that the cyanide treatment changes the surface of the mineral particles to such an extent that these particles do not readily float. The objection to flotation is the cost of marketing the concentrate. Only one smelting concern in Canada or the United States will buy this product at present. The marketing costs on 200, 300, and 400-oz. concentrate are 22, 16, and 13%, respectively. Hugh Rose, commenting on Santa Gertrudis practice, states that flotation concentrate from that silver ore can be treated raw by cyanide, giving a high extraction. The same treatment on Cobalt concentrate gives poor results and it is necessary to roast with salt before attempting to leach. With good chloridization there should be little difficulty in extracting the silver by cyanide or by sodium hyposulphite.

T. R. Jones at the Buffalo has completed a plant for the treatment of this flotation product. The concentrate is pumped to a thickener feeding to an Oliver filter. The necessary salt is added in solution to the cake before it is scraped from the filter-drum. The concentrate is dried in an oil-fired revolving cylinder, is crushed and fed to a hearth-furnace. The calcine is pulverized in a Hardinge ball-mill, mixed with an acid solution to dissolve the oxidized copper, and then drawn on the leaves of a Moore filter. Subsequently the leaves carrying the pulp are immersed in caustic-soda solution to neutralize the remaining acid and then transferred to the cyanide-tank. Most of the silver is extracted in the short treatment on the filter leaves. The residue is pumped to the cyanide-tank, where it receives further treatment and then goes to flotation.

*Abstract from article by R. B. Watson. *Can. Min. Jour.*, March 1, 1916.

Metallurgical Methods at Treadwell

By S. B. Combest

The Alaska Treadwell, Alaska Mexican, and Alaska United gold mines are operated under one management and are commonly called the Alaska Treadwell group. The Alaska Treadwell mills consist of two plants, the 240 and the 300 mills—540 stamps in all. The names of the mills correspond to the number of stamps in each unit. The Alaska Mexican has a mill of 120 stamps. The Alaska United has two mills, the 700 and Ready Bullion, each containing 150 stamps. The total number of stamps in the mills of the group is 960. These several mills, except the Ready Bullion, are supplied from a central crushing-plant, the broken ore being hauled by electric motors to the various bins. At the central crushing-plant, the mine-run of ore is crushed without screening in two No. 12 (K) Gates gyratory machines, delivering to two 5 by 14-ft. trommels, having 2-inch apertures and revolving at 13 r.p.m. The oversize from the trommels goes to four No. 6 (D) Gates gyratory crushers, where the rock joins the undersize from the trommels, and is conveyed by two 40-in. belt-conveyors to a concrete bin of 2000-tons capacity. A sizing-test of the ore at the bins gives the following:

Size	%	Size	%
On 3-in. ring....	6.0	On 48-mesh	0.80
" 2-in. "	28.2	" 65 "	0.65
" 1-in. "	29.25	" 100 "	0.65
" ½-mesh	10.11	" 150 "	0.80
" 4 "	11.65	" 200 "	0.53
" 20 "	7.80	Through 200 "	1.33
" 35 "	2.23		

About 4526 tons of ore is crushed daily.

The Ready Bullion mill is three-quarters of a mile from the other mills, and receives its supply of ore from a separate crushing-plant, at the mine. This ore goes to the mill on a gravity tram, the empty cars being hauled back to the mine by a small hoist. As the metallurgical practice is the same in each of the mills, a description of the methods at the Ready Bullion will suffice for all. The mine-run of ore is dumped from a skip onto a grizzly, the undersize going to the pocket beneath, the oversize to No. 6 (D) Gates gyratory crusher, the crushed ore joining the under-size in the pocket.

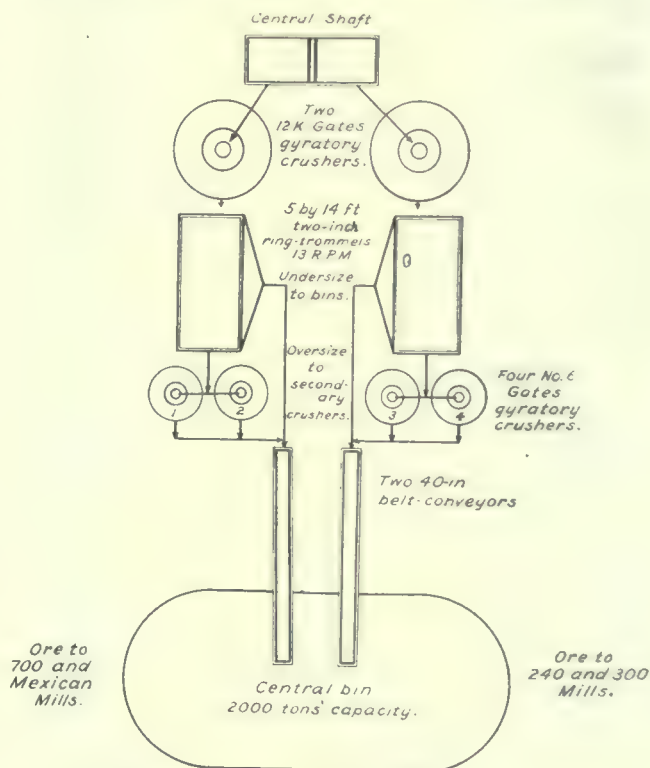

The mill-bins have enough capacity for a 48-hours run. The ore is fed to the batteries by suspended Challenge feeders. The stamps weigh 1239 lb. each for the 300, 700, Mexican, and Ready Bullion mills, but the 240-mill has 1003-lb. stamps. The weight of the stamps is distributed as follows: tappet, 180 lb.; shoe, 175 lb.; head, 594 lb.; stem, 490 lb. The weight of the mortars is 7312 lb.; of the cam-shaft (5½ in. by 8½ ft.), 675 lb.; cam, 225 lb.; die, 140 lb.; cam-shaft pulley, 1275 lb. Total weight of a 5-stamp battery, 17,282 pounds.

The sequence of drop is 1-3-5-4-2; the height of drop

is 9 in.; the number of drops per minute, 100; height of discharge above the die, 6 inches. The ratio of water to pulp, as fed to the battery is 5:1. The average stamp-duty is 4.71 tons per 24 hours, crushed through 20-mesh. The total daily tonnage in 1915 was 4526. The finished product from the stamps gives the following sizes:

Size	%	Size	%
On 20-mesh	6.25	On 100-mesh	8.35
" 35 "	25.00	" 150 "	12.50
" 48 "	12.50	" 200 "	6.25
" 65 "	12.50	Through 200 "	16.65

AMALGAMATION. Mercury is fed into the batteries in all of the mills, although amalgamation on inside copper

COARSE-CRUSHING PLANT AT THE CENTRAL SHAFT.

plates has long since been discontinued. A more thorough mixing of pulp and mercury takes place when the mercury is fed into the mortar-box. The amalgam is collected on outside copper plates that are cleaned-up once each month. The plates are 5 ft. wide and 10 ft. long, and have a grade of 1 in 12. About 51% of the recoverable gold in the ore is won by amalgamation. The loss of mercury averages about 30% of the amount used, about 0.3 oz. of mercury being fed for each ton of ore crushed. The plates are dressed once in 24 hours. The general clean-up is made once a month, the practice being to allow the amalgam to accumulate on the plates.

CLEAN-UP. The plates are steamed for an hour to

PANORAMA OF THE TREADWELL GROUP OF MINES ON DOUGLAS ISLAND, GASTINEAU CHANNEL, AND THE MAINLAND ADJACENT TO JUNEAU.

soften the amalgam. This renders its removal with the knives an easy matter. The accumulated amalgam is put into a barrel with sufficient mercury to make the charge fluid. About 300 lb. of 3-in. iron balls are added and the barrel is filled about three-fourths full of water, after which the man-hole cover is made secure, and the barrel started revolving. It is run over-night. In the morning the small tap-hole opposite the man-hole is opened and the barrel again revolved. In this manner the contents are slowly discharged into a 4-ft. batea. To the charge in the batea are added five or six 6-in. iron balls, and the batea is then started and kept in motion until all the slimed concentrate has worked to the surface and is washed off. This is collected and returned to the battery. The batea is then stopped, the iron balls taken out, the metallic iron removed from the amalgam by means of a magnet, the mercury screened through an eight-mesh screen—a gold pan with $\frac{1}{8}$ -in. holes punched in the bottom. The portion remaining upon the screen is called 'base bullion' and is kept separate.

The screened mercury is then passed into canvas bags that are placed in a hydraulic amalgam-press, where the excess mercury is squeezed out. The dry amalgam thus obtained is worth about \$6.30 per ounce.

LATER. Since this was written, amalgamation has been discontinued at the Treadwell mills. All the value of the ore now is recovered from the concentrate.

CONCENTRATION. The mill-pulp, after passing through ordinary mercury-traps, contains 49% of the recoverable gold. From the traps the pulp goes to Frue vanners. These machines are 6 ft. wide in all of the mills except the 240 and Mexican, where they are only 4 ft. wide. There are two vanners to each five stamps. The belts are set on a grade of $4\frac{3}{4}$ in. from centre to centre of the travel-cylinders. The number of vibrations is 196 per minute, and the belt-travel 5 ft. per minute. Each vanner treats about 12.5 tons of pulp per 24 hours. The practice is to run the machines so that the concentrate will carry about 35% sand, which seems to afford the most satisfactory result. The tailing leaving the vanners assays 16.5 cents in gold and is allowed to run to waste.

The concentrate from the vanner-boxes is shoveled daily into cars and taken to the cyanide plant for treatment.

MILLING COSTS. The average cost of milling one ton of ore at each of the several mills in 1915 is given below:

	240	300	700	Mexican	Ready Bullion
	mill	mill	mill	mill	mill
Crushing	\$0.038	\$0.038	\$0.037	\$0.040	\$0.022
Tramming	0.014	0.016	0.015	0.016	0.019
Stamping	0.211	0.189	0.170	0.192	0.182
Concentrating ..	0.066	0.059	0.052	0.058	0.070
Cyaniding	0.087	0.087	0.088	0.092	0.086
Total	\$0.416	\$0.389	\$0.362	\$0.398	\$0.379

CYANIDE PRACTICE. The cyanide plant is adapted to the all-sliming method of treatment, and handles all the concentrate produced in the five mills.

A 75-hp. electric hoist hauls the cars to the bins, where

samples are taken with an auger while the concentrate is still in the cars. Two samples are taken from each car. The cars are then weighed, moisture determinations made, and the contents computed, after which the cars are dumped by tipples into two 100-ton conical steel bins. From these bins the concentrate is fed directly to Abbé tube-mills. There are three of these, two 5 by 22 ft. and one 4 by 16 ft., each equipped with the spiral feed. The larger mills will grind about 90 tons of concentrate in 24 hours. As the total concentrate sent to the grinding-plant daily is about 105 tons, the second of the larger mills is used as an auxiliary when the concentrate begins to accumulate.

The smaller tube-mill is placed between the larger ones and below the tube-mill floor. This particular mill is charged with 2-in. iron balls and is used to remove the metallic iron from the main circuit, otherwise the battery-iron would accumulate in the grinding-circuit and reduce the capacity correspondingly. The small mill is operated with four tons of balls, on a charge of about the same weight. This mill makes $30\frac{1}{2}$ r.p.m. and is driven by a 50-hp. motor.

The larger tubes make 28 r.p.m. and are loaded with 10 tons of $2\frac{1}{2}$ -in. Danish pebbles. The load of concentrate weighs about the same. Each mill is driven by a 100-hp. motor. The discharge is distributed equally to four 5 by 16-ft. Dorr duplex classifiers, the oversize being returned. A separate classifier is used to dewater the material going to the smaller tube-mill, the feed from which is drawn from the coarse return to the large tubes. The discharge from the small 'tube' is then elevated into the main circuit, the metallic iron having been ground to pass 200-mesh, after which it overflows with the slime.

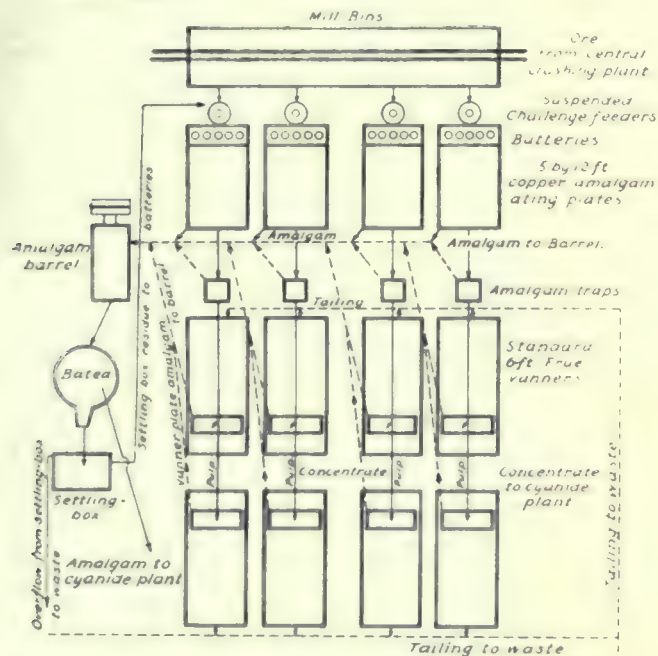

The discharge from the tube-mills is dewatered in a $4\frac{1}{2}$ by $21\frac{1}{2}$ -ft. Dorr thickener, the thickening apparatus making one revolution in 8 minutes. A 1-hp. motor drives this mechanism, and a 2-in. valve controls the thickened product. The ratio of ore to solution on entering the thickener is as 1:4; on leaving the thickener it is 1 of solution to $1\frac{1}{3}$ of ore. The overflow is clear and goes to the gold-sump. The thickened pulp is sent to twelve 10 by 30-ft. Pachuca tanks, or Brown agitators. The charge for a tank is 40 tons of pulp, to which 30 to 40 tons of barren solution is added. Agitation is then commenced and continued for four hours, when the charge is allowed to settle for 8 hours. The clear solution is decanted, going to the gold-sump. Solution is again added and agitation recommenced and continued four hours as before. This is done three times. The total time of treatment of a charge in these tanks is 81 hours, distributed as follows:

	Hours
Filling	8
Agitation	12
Settling	29
Decanting	29
Adding solution	1.5
Agitating and pumping residue to double cone...	1.5

After the third agitation in a Pachuca tank the charge is pumped to a double-cone storage-tank, which is used as a storage-reservoir for the filter-presses.

FILTRATION. All of the solution decanted and the overflow from the thickener are gathered in three 75-ton sump-tanks from which this solution is forced through a clarification-press by a 6-in. pump, the clear liquor going to the precipitation-room. Pulp from the double-cone classifier is drawn into the filter-press, where it is given a wash with barren solution, after which the moisture is reduced to about 12% by compressed air. The press is

1.7 lb. cyanide per ton, which is the standard strength of solution throughout the mill, and practically all the cyanide added is introduced at this point. The head-solution contains on an average of \$8 per ton gold, and the tailing-solution from the presses is kept down to 5 cents per ton. The barren solution is run to a large storage-tank from which it is pumped as required. Each of the five Merrill presses holds 800 lb. dry precipitate. The filter-cloths are of heavy sheeting, covered with two

FLOW-SHEET OF STAMP-MILL AT TREADWELL.

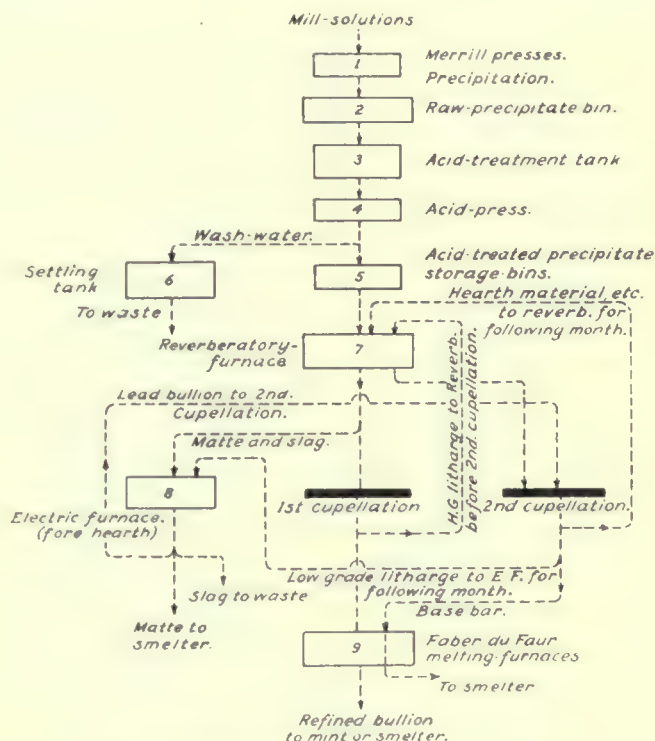

then sluiced with water and the pulp discharged to the waste-dump. The time required to each charge in the press is as follows:

Operation	Minutes
Filling	10
Filtering	6
Blowing back pulp	8
Filling with wash-water	10
Washing	20
Blowing back wash-solution	5
Drying with air	30
Sluicing pulp	80

Total time 2 hr. 49 min.

The capacity of the Treadwell presses is 16 tons of dry pulp. Formerly two Kelly presses were used, and they are still occasionally employed for this purpose. The capacity of the Kelly presses is 3 tons of dry pulp, and their operation requires 45 minutes, the discharge containing 12% moisture.

PRECIPITATION. All of the clarified solution is sent by an Aldrich triplex pump through five Merrill precipitation-presses. An emulsion of 0.2 lb. of zinc-dust and 0.5 lb. of lead acetate is added at the suction end of the pump. The strength of the solution is raised here to

FLOW-SHEET OF TREADWELL REFINERY.

thicknesses of filter-paper. The presses are run until the gauge indicates a pressure of 35 pounds.

REFINING. When the precipitation-presses are cleaned the solution is shut-off and the precipitate is washed with fresh water. The moisture is then blown down until the dripping from the discharge-cocks ceases. This generally requires 45 minutes. The presses are then opened and the precipitate dropped into pans, from which it is shoveled into steel boxes and taken to the refinery, where it is weighed and dumped into a steel storage-bin. From this bin the precipitate is taken out as needed for acid-treatment. After acid-treatment the precipitate is given a wash with hot water and is then pumped into a Merrill press and the moisture-content blown down to about 20%. The press is then opened and the precipitate transferred to the small steel storage-bins near the reverberatory furnace. The precipitate is taken from these bins and, without further drying, is mixed with fluxes and charged to the furnace. The gold is collected by lead and the lead cupelled, leaving gold bullion about 0.890 fine. All the by-products, such as high-grade slag, litharge, matte, sweepings, and hearth-materials, are re-smelted. Melting is done once in each month.

An analysis of concentrate gives the following:

	%		%
Fe	41.8	SiO ₂	32.0
S	21.37	Al ₂ O ₃	1.20
CaO	2.18	Au	\$45

The iron occurs in the form of pyrite, pyrrhotite, and marcasite. As pyrite is only slightly affected by exposure to the atmosphere, it is the decomposition of the pyrrhotite and marcasite that introduces the cyanicides. The reaction is supposed to be:

Calcium sulphate is slightly soluble in water, and more so in cyanide solution, unless other soluble sulphates are present. Lead acetate is added to the solution as it comes in contact with the concentrate. Barium chloride was used to some extent in place of lead acetate to replace some of the sulphates entering the solution and gave better results, but the present high price of barium chloride has led to the substitution of lead acetate. To prevent oxidation the concentrate is kept under water at the mills until it is shoveled into cars just before treatment begins. About 5.4 lb. of lime is added to the concentrate in the cars and the charge becomes well mixed by the time the concentrate comes in contact with the cyanide solution. The following reactions then take place:

The reaction with barium chloride in the presence of calcium sulphate is:

The lead acetate is added to the concentrate as it enters the tube-mill, the amount being 0.35 lb. per ton of concentrate.

LOSSES AND EXTRACTIONS DURING TREATMENT

During the grinding cycle:

Loss of cyanide	0.90 lb.
Loss of lime	5.40 "
Consumption of lead acetate per ton of ore.....	0.35 "
Extraction during grinding	75%

During classification, transit, and thickening:

Loss of cyanide.....	0.02 lb.
Loss of lime	0.01 "
Extraction	4.40%

First treatment in Pachucas, or Brown agitators:

Loss of cyanide	0.70 lb.
Loss of lime	0.33 "
Extraction	10.5%

Second treatment in Pachucas:

Loss of cyanide	0.23 lb.
Loss of lime	0.33 "
Extraction	3.5%

Third treatment in Pachucas:

Loss of cyanide	0.30 lb.
Loss of lime	0.33 "
Extraction	3%

During filtration:

Loss of cyanide	0.08 lb.
Loss of lime	0.08 "
Extraction	1%

The ratio of the total amount of solution used in classification, grinding, agitation, and in the washing-presses is about 6.5:1. The total amount of solution treated in the precipitation-presses is about 500 tons. On entering the cyanide-plant the concentrate contains 12.5% moisture and it leaves carrying about the same proportion. During each Pachuca treatment 5 lb. of lead acetate is added; protective lime is carried at 1.75 lb. per ton of solution; and the cyanide content at 1.7 lb. free cyanide. The total consumption of cyanide per ton of concentrate is 2.23 lb.; of lime, 6.48 lb.; and of lead acetate, 0.69 lb. The total extraction is 97.03%.

As the concentrate contains traces of copper, the solution gradually becomes charged with an appreciable amount of it, which necessitates the addition of lead acetate at the presses. The acetate added in the mill is entirely precipitated by the sulphur compounds before entering the Merrill presses. So an additional quantity is added here. From an examination of the zinc, it is evident that the copper and the gold cover the zinc in such a manner that no further action is possible between the zinc and the solution. The addition of the lead acetate at this point probably results in the following reaction:

The lead acetate in contact with metallic zinc serves to precipitate metallic lead, in the form of a sponge; this, with the excess of zinc sets up a galvanic reaction sufficient to cause the gold and copper to be precipitated in a loose and pulverulent form, which readily scales off from the zinc, permitting further action between the zinc and the pregnant solution.

The analysis of the zinc-dust gives the following:

	%		%
Total zinc	90.7	Iron	1.3
Metallic zinc	85.0	Insoluble	9.55
Zinc oxide	5.0	Through 200-mesh	96.0
Lead	1.9		

REFINING. The dry weight of precipitate received at the refinery each month is about 6500 lb. From 1500 to 1700 lb. of raw wet precipitate is taken from the bin. The agitator in the acid-tank is started, one ton of hot water is admitted, and the precipitate is then charged slowly, after which sulphuric acid is added. As soon as the violent reaction has subsided a sample is taken of the liquid, which is tested for acidity with methyl orange. If the sample is alkaline, more acid is added and the solution again tested. This is continued until the solution is slightly acid. The tank is now filled with hot water, the agitator being kept in motion. The capacity of the tank is 10 tons, of which about 8 tons is water. The agitator is then stopped and the solution allowed to settle. The clear liquor is siphoned off and pumped through the acid-press, which is a 20-frame Merrill precipitation-press. The frames are covered with several leaves consisting of 22-oz. duck, drilling, sheeting and two filter-papers. The waste solution runs about \$0.08 per ton. The acid-pump is a plate-lined 3-in. Byron Jackson centrifugal. After the first wash is off, the agitator is again started and the tank re-filled with hot water and the sludge pumped into

the press, which holds about 700 lb. (dry weight) of precipitate. All of the raw precipitate is treated in this manner. The treated precipitate is placed in the small steel bins near the furnace.

Analysis of precipitate both before and after acid-treatment gives the following:

	Before treatment	After treatment
	%	%
Au	10.0	16.0
Ag	0.6	1.2
Cu	8.0	16.96
CaO	15.0	2.6
S	2.8	10.0
Fe	0.7	1.4
SiO ₂	0.45	1.0
Zn	50.0	4.0
Pb	11.6	24.0
Al	0.2	0.4

A flux is calculated from the above analysis. The S is considered as a Cu, Fe, Pb, Zn matte. About 20% of lead in the first-run matte gives the best grade of bullion. If all of the lead is reduced, copper is also thrown down and causes trouble during cupellation. The remaining lead is thrown down from the matte in a separate fusion. The lime, alumina, and a part of the zinc is calculated as forming a mono-silicate slag. The method of calculating the flux-charge is: the copper into Cu₂S (matte), the iron as FeS, 20% of the zinc as ZnS. The remaining zinc is calculated as ZnO in a silicious slag.

The usual charge for the furnace is 250 lb. (wet weight), of precipitate, which is equivalent to about 200 lb. dry weight. The precipitate, which is not dried before smelting, has been determined by careful analyses to contain the constituents shown at the top of the following page:

1. 1800-ton solution storage-tank.
2. 75-hp. electric hoist.
3. Two Osgood track-scales.
4. 50-ton fresh-water tank.
5. Two car-tipples.
6. Two 100-ton cone-bottom bins.
7. Callow cone-classifier.
8. Two Callow cone-classifiers.
9. Dorr duplex classifier.
10. Two Dorr duplex classifiers.
11. Two 22 by 5-ft. Abbé tube-mills.
12. Two Dorr duplex classifiers.
13. 4 by 16-ft. Abbé tube-mill.
14. Cone-classifier air-lift.
15. Coarse-return air-lift.
16. Two Callow dewatering cones.
17. Two 2nd stage dewatering cones.
18. Double-cone storage (W.S.)
19. Double-cone storage (pulp).
20. Twelve 10 by 30-ft. Pachucas.
21. Two Kelly filter-presses.
22. Two Treadwell presses.
23. Two 4-in. Byron Jackson centrifugal pumps.
24. Automatic zinc-dust feeder.
25. Zinc-dust mixer.

	Lb.		Lb.
Copper	33.9	Iron	2.8
Sulphur	20.0	Zinc	8.0
Lime	5.2	Lead	48.0

The practice here is to allow 3.75 lb. of copper to one of sulphur. Therefore the copper content will satisfy 9.04 lb. of sulphur. The iron, as FeS, will take up $2.8 \div 1.75 = 1.6$ lb. of sulphur; 20% of the zinc, as ZnS, equals $1.2 \div 2 = 0.6$ lb. of sulphur. The lead content of the matte at 20% is equivalent to 1.6 lb. of sulphur. The total combined sulphur is therefore:

	Lb.		Lb.
Cu ₂ S	9.04	PbS	1.60
FeS	1.60		
ZnS	0.60	Total	12.84

An additional 10% of the sulphur is allowed for loss by oxidation in the furnace, this accounts for 2 lb. more, a total of 14.84. As there was 20 lb. of sulphur in the charge, there still remains 5.16 lb. to be expelled. To accomplish this, metallic iron in the form of strips of old battery-screens is added in the following ratio: 5.16 S \times 1.75 (the iron factor) = 9.03 lb. of screen to be added. The lime is calculated as follows:

SiO₂:2CaO :: 1:1.85 or $5.2 \div 1.85 = 2.81$ lb. of SiO₂ to be added. An excess of 10 lb. of silica and 15 lb. of soda-ash is also added to the charge. The lead is reduced with pulverized coke, which is added at the rate of 1 lb. of coke to 10 lb. of lead.

A charge is made up in the proportions indicated and brought to a state of fusion. The silica and iron are then regulated according to requirements. If the slag is too thick, the silica is lessened, if too thin, running off like water, leaving a thick pasty mass on the surface of the matte, silica is added. The thick mass is generally zinc that has not entered either the matte or the slag, and an excess of silica will take it up. The proportion of iron is decreased if a crust begins to form on the jacket of the hearth. If the matte indicates, by its crystalline structure, that there is not enough iron present, more iron is added. A charge will ordinarily consist of:

	Lb.
Precipitate (wet weight)	200.0
Iron (screen-scrap)	9.03
Silica	12.81
Soda-ash or crude borax	15.0
Coke	4.80

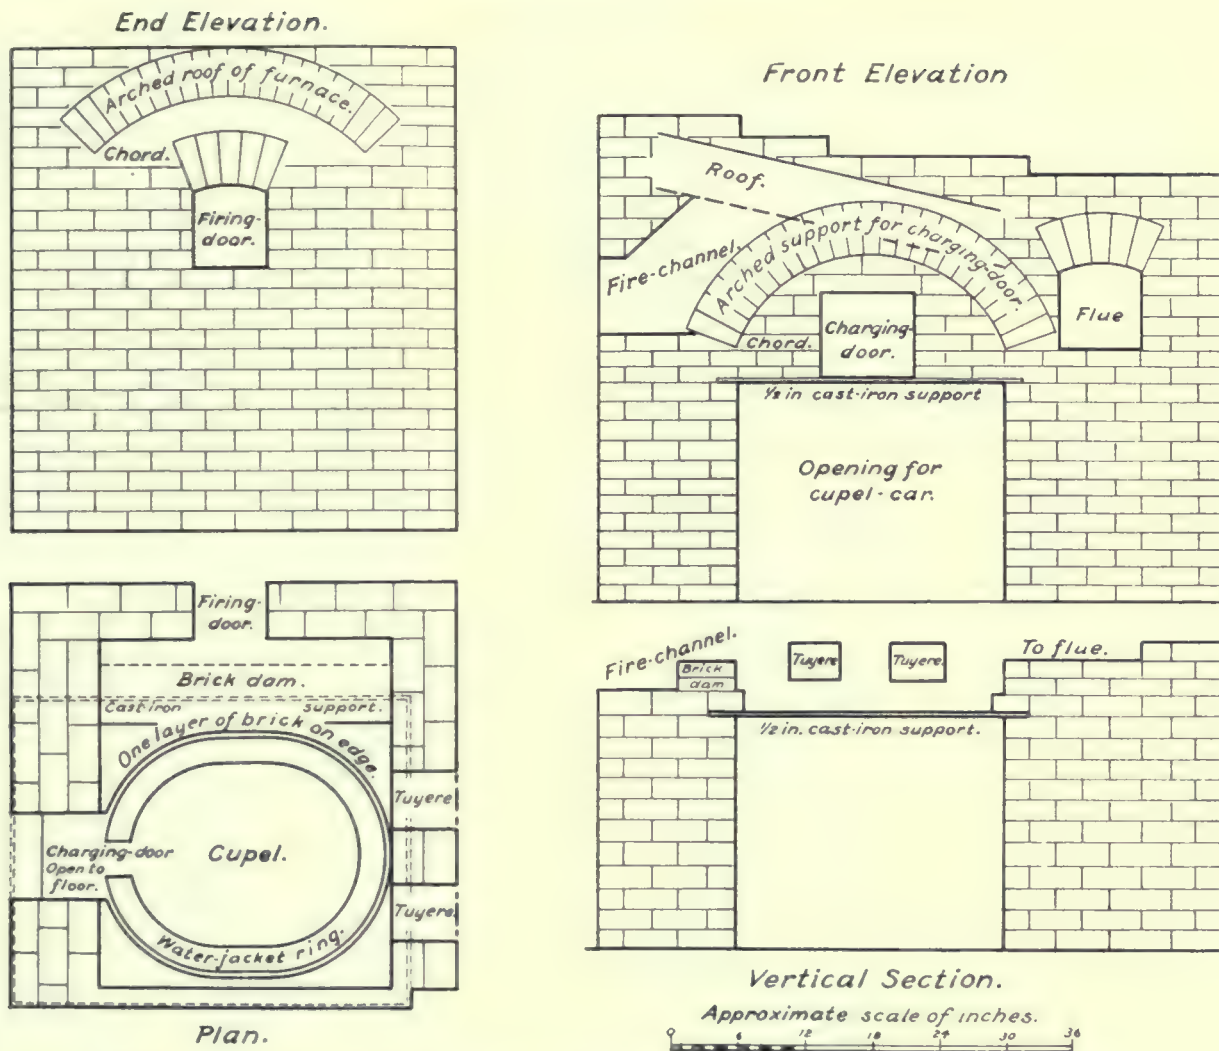

This is charged into a small reverberatory furnace, burning crude-oil. The hearth of this furnace consists of a horse-shoe cast-iron water-jacket, closed at the open end with magnesite bricks, which are used as the lip of the hearth. The space inside the jacket is filled and tamped solid with a mixture consisting of 200 lb. of limestone, crushed to pass an 8-mesh screen, 70 lb. cement, and 20 lb. of water. After tamping, the centre is hollowed out to shape. In starting the furnace a seasoned hearth is run under the car-support and the sides are luted carefully with fire-clay. The hearth is bolted to the perforated cast-iron plate-bottom. The hearths are made up several weeks before they are required, and are allowed

to dry slowly, which prevents checking. A wood fire is started on the hearth and the furnace heated gradually. As soon as the hearth is hot enough, sufficient lead is introduced to cover the bottom of the hearth. A few shovelful of matte are added, which helps to start fusion. As soon as this is melted, the charge is added. The heat is not allowed to rise much above the melting-point of the charge. After quiet fusion the slag is stirred with an iron rabble and allowed a few minutes to settle. Then the slag is tapped. A shovelful of cold slag is thrown on the surface to prevent any moisture in the succeeding charge from coming in direct contact with the molten matte. When all the material has been smelted, the slag and matte are drawn off separately as far as possible and a shovelful of lime thrown over the surface of the bullion to thicken the remaining slag, after which it can be safely skimmed off with the iron rabble. The bullion is now ready for cupellation. As the slag is tapped from the hearth it is allowed to flow into a small electric furnace, used as a fore-hearth. This furnace is provided with wheels and can be run back when the reverberatory furnace is being charged. Litharge and ground coke are added to the fore-hearth and the molten slag is allowed to stand until ready for the next tapping of the reverberatory. The electric fore-hearth is now tapped into slag-pots. The lead is drawn off at intervals from a separate tap-hole, which is a few inches lower than the slag-tap. By this method the reverberatory-furnace slag is lowered from \$50 per ton to between \$1 and \$4 per ton in one operation. The lead bullion from the fore-hearth is added to the reverberatory and cupelled down. The matte, litharge, and last few charges of slag are re-run in the reverberatory furnace, passing through the fore-hearth as in the previous operation.

CUPELLATION. When the surface of the bullion is clean the blower is started and air is blown across the surface of the charge toward the charging-door. The air-pressure should be sufficient to cause slight ripples on the surface of the molten mass. The lip of the hearth is cut-down to the level of the lead and the hearth tilted slightly, until the litharge begins to flow.

Care must be exercised in tilting the hearth, otherwise lead bullion will flow over. A wide smooth lip is best. The presence of small bubbles or globules indicates that metallic lead is overflowing. An examination of litharge caught on a shovel will show whether metallic lead is escaping. In case lead is overflowing, the hearth is tilted back until the lead ceases to show. If there are no other impurities present than lead, zinc, sulphur, and a small amount of copper—2% or less—the addition of a quantity of lead equal to the weight of gold present will clear the bullion of these impurities. If much copper is present more lead will have to be added to effect this.

Toward the end of cupellation a dark line will appear, beginning directly under the tuyeres and gradually working toward the overflow. This advancing line marks the division between the fine gold and the base metal floating on its surface. The molten gold should now present a bright mirror-like surface, though the

PLAN AND SECTIONS OF REFINING-FURNACE.

metal is likely to bubble and boil a little at this period. As soon as the dark line passes over the lip of the furnace, the refining is complete and the bullion is poured into molds of about 500 oz. capacity, the bottoms of which have been covered previously with dry borax-glass to prevent spattering. As it has been found impossible to pour a satisfactory bar directly from the hearth of the reverberatory, the bullion is cast in the small molds, as above described, and later melted in a Faber du Faur tilting-furnace, and cast from this into molds having a capacity of 2000 ounces. During the last few minutes of cupellation the heat is raised in the furnace to oxidize the last of any lead that may remain and to keep the gold molten, the refined gold requiring a higher heat. In case much copper is present and there is not sufficient lead to absorb and remove it, the surface of the bullion will appear dark-red and a slight crust will appear. If it is necessary to bring the bullion up to a higher degree of fineness, more lead is added and cupellation continued until the surface of the metal is mirror-like. The by-products of the first run consist of matte, approximate weight 800 lb.; litharge, 600 lb.; hearth-material, 150 lb.; slag, 400 lb. It has long been the usual practice here to make an analysis of the matte before re-melting

to determine the gold, sulphur, lead, copper, and silver contents.

RE-SMELTING. The same hearth is generally used to re-smelt the by-products. A charge is made up of the following: matte, 40 lb.; litharge, 30 lb.; hearth-material, 7.5 lb.; slag, 20 lb. Metallic iron is introduced to combine with the sulphur released by the lead. Coke is added to reduce the litharge, and about 5 lb. of silica and 8 lb. of soda-ash are also added to combine with the oxides of iron, formed during smelting. The slag is tapped into the electric fore-hearth and treated in the same manner as in the previous smelting.

Analyses of the matte before and after re-smelting generally approximate the following:

	Before	After
Gold	\$212.90	\$11.57
Silver	123.90	53.01
Copper	38%	35.1%
Lead	16.7%	2.9%
Zinc	2.9%	5.2%
Sulphur	20%	19.8%
Iron	7.7%	16.9%

The matte from the fusion is crushed, sampled, and sacked. When a sufficient quantity has accumulated it is shipped to the smelter, the copper content more than

paying the expense. The slag averages about \$2 per ton and is thrown on the dump. The hearth is broken up and the portion containing metallics is smelted at the next melt. The remaining portion is re-ground and used again. The fire-brick and furnace-chipping are ground in the amalgam-barrel, the coarse gold amalgamated, and the fine sent to the tube-mills to be cyanided. The average value of this ground material is about \$100 per ton. Refinery sweepings and flue-dust are run with the regular melt, being introduced at the rate of 10 lb. with each charge.

The gold, after cupellation, is weighed into the quantity desired for each bar and this is melted in an oil-fired Faber du Faur tilting-furnace. The bullion is sampled, when molten, by the 'dip' method. It is thoroughly stirred with a graphite rod before taking the sample. A half-inch hole is bored in a piece of graphite, which is then heated to redness. This graphite sampler is plunged into the centre of the molten gold. It is then removed and allowed to cool, when, generally, the slug of gold will come out clean, so that the sampler may be used again. The average weight of bars is 1800 ounces. After casting, the bar is allowed to stand until the gold has solidified, after which it is doused and cooled with water and the slag hammered off. It is then treated with concentrated nitric acid, washed with water, the gold dried and weighed.

AMALGAM. The mill amalgam is brought to the refinery each month, retorted, cast into bars, sampled, weighed, and shipped to the Mint. The amalgam from each mill is weighed before retorting and 99% of the difference in weight between the amalgam and the sponge after retorting is returned to the mill as metallic mercury. The loss of mercury in retorting is slightly less than 1%. The retort-furnace is of the double-cylinder type. The amalgam is packed in 'boats' that are placed in the retorts. Usually it requires two charges to treat all of the amalgam. After charging and carefully sealing the retort, the furnace is fired slowly, the heat being increased gradually for about 7 hours, when it is raised to a bright-red to drive off the last of the mercury. The furnace is then allowed to cool somewhat, and the cover of the retort is removed, the boats withdrawn, and the sponge of gold taken out, weighed, and melted. This bullion is sampled in the same manner as the cyanide bullion, but it is marked and kept separate. The difference between the Mint returns and the Treadwell returns on shipments aggregating \$270,000 averaged \$107. The Mint assays are slightly lower than those at Treadwell. The difference in weight of the bars was 0.52 oz., the Mint weight being the lower. These figures are on gold only.

BASE-BULLION. The amalgam containing the base-bullion is retorted each month to recover the mercury, the sponge being stored until sufficient has accumulated to make a bar weighing from 600 to 1000 oz., when it is melted in a Faber du Faur furnace. As the molten metal attacks the crucible, an old crucible is generally used for this melt and is discarded afterward. To 1000

oz. of base 'sponge' are added 5 lb. of silica, 5 lb. of borax-glass, and about 3 lb. of sulphur (the latter to form matte with the iron). A part of the copper also goes into the matte. The resulting bars run from 20 to 100 fine, the base being principally copper. These bars are shipped to the smelter. The total monthly cost of retorting, smelting, sampling, and casting the amalgam into bars is \$87, of which the labor cost is \$58, and supplies \$29. The cost per fine ounce is \$0.012.

Magnesium

*The metallurgist has been coquetting with magnesium for half a century. We can get its oxide cheaply and in abundance, its salts are not difficult to prepare, we know their properties to a considerable extent, we know almost all the properties of the metal which bear on its isolation, yet the industry lags and halts. To prepare by tedious methods the anhydrous double chloride, and then to electrolyze it about as Matthiesen did fifty years ago, is nearly all that can be said with certainty about its present metallurgy. At any rate, using magnesium oxide costing a few cents per pound, the metal sells for about as many dollars per pound, and there is still a scarcity. W. M. Grosvenor, in a paper before the American Electrochemical Society, summarizes the present methods of production and the uses of the metal. He also suggests the great field open for radically new methods of production. The point of attack should be to reduce the oxide directly. The halogen salts are hygroscopic, and the halogen is destructive of the reducing apparatus. It is almost certain that proper research will enable the electrometallurgist to feed magnesium oxide (MgO) directly into an electrolytic bath of fused salts, and take magnesium or magnesium alloy from it. The pure metal will float on almost any fused salt, but alloys with heavier metals may be made that will sink, and many of its alloys have immediate useful applications.

The possibilities in the metal industry from having reasonably cheap magnesium are interesting. The stiffening of magnesium to produce strong alloys with a specific gravity not over 2, has not been properly studied. It is possible that alloys analogous to dur-alumin may be discovered, as strong as soft steel and only 30% of its weight, useful in aeroplanes and dirigibles. Such alloys may also largely displace aluminum alloys in the automobile industry, with a saving in weight, which will compensate for higher first cost. The uses of magnesium will also be extended for deoxidizing brass, bronze, nickel, and Monel metal, since it is a much stronger deoxidizer than aluminum. In fact, aluminum has blazed the way to numerous uses for which magnesium, as soon as it becomes cheaper, will compete and replace its older sister. Magnesium ore is as plentiful as that of aluminum, and there will inevitably be a large future for magnesium as one of the common metals of every-day life.

*Abstract of article in *Jour. Ind. & Eng. Chem.* V. 8, No. 8, p. 736, by J. W. Richards.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

MEXICO CITY

RESTORATION OF LANDS TO INDIANS.—METALLIC MINERALS AND PETROLEUM NATIONAL PROPERTY.

The new constitution is a fact that must be confronted by all foreigners doing business in the Republic, wherefore comment from one on the ground may be useful. In the first half of the third paragraph of article 27, the nation is given the right to control all lands and waters in the public interest, even those transferred to private possession. In the second half of the paragraph is begun the treatment of the problem of the Indian communal lands, the appropriation of which by the Diaz *científicos* helped to bring on the present revolution. In declaring their restoration to the Indians a work of 'public utility,' the first step toward the solution of the problem is taken. The placing of all metallic minerals under national ownership is merely a recognition of an established fact, for Mexico, like most other Latin countries, has never conceded anything more than a lease-hold to metallic deposits. Formerly this was also the case with non-metallic minerals, but by the mining law of 1883 these were granted to the owners of the surface rights. This was done by the Gonzales administration. The evils of that law as applied to petroleum land have become generally recognized. The resumption by the government of ownership to non-metallic minerals, as now proposed, without any attempt to relieve their present private owners of disability flowing from the change, is however, a violent method of handling the problem. In the sixth paragraph, where the national ownership of minerals and waters is declared 'inalienable and imprescriptible' and their private possession is made contingent on their proper development and use, a stand is taken in the public interest which is far in advance socially of anything yet attained by the United States. The sole right of acquiring the ownership in lands and waters, and concessions for working Federal minerals and waters is bestowed upon Mexican citizens only. At the pleasure of the Government, however, foreigners may be conceded the same privileges on condition of renouncing the protection of their home governments under pain of forfeiture.

Fraction IV attempts to limit the monopoly of agricultural land by prohibiting its ownership by stock companies and strictly limiting the area owned by mining and industrial companies. This would be of doubtful utility if applied only in the future, but, as it applies to the many existing companies and will greatly injure or ruin them, it must be characterized as unjust. The ancient privilege of communal administration of *egidos* was unwisely taken from the Indians by the law of 1856, and its restoration is essential for the well-being of these communities. Fraction VII, by prohibiting a civil corporation from owning, managing, or loaning money upon real estate, except the buildings is another attempt to limit land monopoly; but like all arbitrary restrictions upon the free play of individual industrial activity, it is of dubious value. The ninth paragraph voids nearly all the transfers of the land of the Indian *egidos* that have taken place since the process begun by the law of 1856. A few classes of titles are not wholly repudiated, but the owners are allowed to retain only 50 hectares each (123.5 acres). Most titles to the communal lands seem to be repudiated by this decree, even when derived through actual purchase from the Indians. Thus many mining companies are in danger of losing their surface holdings.

Whatever the injustice to the Indians from the deslinde (survey) laws of Diaz, it certainly only aggravates the past wrongs to now dispossess indiscriminately and without compensation nearly all present holders of *egido* lands, many of whom have spent their savings in improving them. Disregarding entirely the Mexican statute of limitation for fraud, fixing 20 years as the limit, this decree by unsettling such titles dating 60 years back, promises a carnival of graft by the corrupt legal profession of Mexico. Compared with this gross violation of vested rights, the Zapata 'Plan of Ayala' for the restitution of the *egidos* seems moral and moderate. Each State legislature is given power to decree the maximum area of ground that a single owner can legally possess. Any excess over the assigned limit must be divided up by its owner with the time and under the conditions to be prescribed. If the owner refuse to carry this out his property will be expropriated. The owner must accept for his excess lands an annuity which cannot be larger than that required to amortize the sale-value in 20 years, or to allow 5% interest. The owner must accept payment in a new issue of State bonds, and an 'inalienable family patrimony' is provided for, evidently intended to prevent the present land-owners from collecting anything at all from the land-buyers in case the new State bonds prove worthless; an event not at all unlikely in view of the recent scandalous history of Carrancista finance. This whole scheme is a thinly-disguised legal veil for effecting the benevolent program of the anarchist 'Regeneracion' of Los Angeles, California, to confiscate Mexican rural property and distribute it among the peons.

Article 33 is derived from the old one of the same number, but goes further in its anti-foreign animus. Formerly the expulsion of 'pernicious' foreigners was authorized, and these could appeal to their ambassadors to establish their innocence. By permitting the Mexican president 'to expel any inconvenient foreigner without trial' the new article illustrates the impudence reached by the anti-foreign faction as a result of three years of non-interference, either at home or from abroad, with their vicious propaganda. All important offices, like that of state governor, supreme judge, senator and deputy can be held only by native Mexicans. By these prohibitions Mexico would be deprived of the political services of talented naturalized foreigners.

The labor rules seem to be derived from those of New Zealand, without considering the differences in character of the laboring people there from those in Mexico. Limiting a day's work to 7 or 8 hours simply means that Mexico's annual output will be only 80% of what it might be under the 10-hour day, the one best suited to the present untrained condition of the peons. Establishing the minimum wage and the right of workmen to share in their employers' profits puts Mexican industries at the mercy of the local Boards of Conciliation, that fix the amount of each. It changes employers into mere salaried managers for their workmen, who would become the real owners of all enterprises. These provisions of the constitution will doubtless cause not only the ruin of the owners of great enterprises, but a reversion of such establishments to a simple medieval type, which is the only one that can be understood by Mexicans. Requiring cash wage-payments, along with the clause providing for wage payments to be made at least once a week, will destroy the system of many mining companies, which involves monthly pay-days and guaranteed grocery stores. The monthly pay means monthly instead of

weekly debauches, while the guaranteed stores provide food for the families and allow the men only some surplus cash for wasting on booze.

In a sort of apology for the constitution, recently published by Licenciado Rojas, president of the Constituent Assembly, he states that 60% of the lawmakers were military and unused to legal constructions. If he had added to this admission the fact that hardly a dozen of the non-military lawmakers were competent to legislate on natural resources or industrial relations, he would have improved his statement. The corrupt ex-Minister of Education, Palavicini, was one of the leaders in framing the confiscatory anti-religious legislation and as he is personally a Catholic adherent, it is rumored that he was paid by the Jesuits to make the constitution so absurd and unjust as to win friends for the reaction. The anarchist projects were inserted through the influence of Gen. Cándido Aguilar, vice-president of the Constituent Assembly and Minister of Foreign Relations. Aguilar represented Vera Cruz with its I. W. W. locals of the great cotton-mills of Rio Blanco. He was a poor Vera Cruz farmer in 1911, but his patriotic struggles have made him a multi-millionaire.

However it originated, the new constitution is a legal fact and has to be faced as such, both inside and outside of Mexico. It can be altered only by an amendment initiated by two-thirds of those voting in Congress and approved by a majority of the State legislatures. By the confiscatory clauses of Art. 27 and 123, all industrial and religious property in Mexico has been as neatly laid open to legal spoliation by the Carrancistas as a basket of fat oysters might be pried open by a sharp knife for one of the banquets so often given to the First Chief. The Carrancista leaders consider the world as it is rather than the world as it ought to be. Threatened with the loss of foreign credit if they proceed to enforce their constitution, they can wisely afford to take the risk in exchange for an unlimited opportunity of rewarding the faithful with the tangible foreign property already planted in Mexico.

JOPLIN, MISSOURI

JOPLIN DISTRICT ABLE TO MEET ALL DEMANDS FOR ZINC.—NEW STRIKES DAILY.

From the standpoint of preparedness for the supply of zinc and lead for munitions for our national use, in case of war, the Joplin district is in a position of unusual importance at this critical time. Never in the history of the district has there been such a production of high-grade zinc-blende ores available for 'brass special spelter.' The Joplin district can supply from 8000 to 12,000 tons of high-grade zinc-blende, of which 60 to 65% would be of such a grade as to meet the requirements for spelter used in the manufacture of brass shells. In addition to this, there is a potential production available of 4000 to 6000 additional tons by the end of June. Besides this great contribution of one of the necessities to the national defence, the Joplin district, together with south-east Missouri, can supply an equal quantity of high-grade pig lead.

Besides this material advantage and a readiness for preparedness there is the spirit of co-operation among the operators of the district to aid in the defence of the country to a degree far beyond that accredited by the press of the country to the Middle West. It was from a meeting of the Joplin district's mine operators that one of the earliest and strongest endorsements of President Wilson's armed neutrality law was sent to the President and to the district's Congressional representative.

The outstanding feature of new developments of the district consists in the remarkable number of new strikes now being made in the Waco field at the northern extremity of the Joplin district. This new field is at the northern end of the new trend of ore development, and the character of the new strikes has been so rich that they have attracted even more at-

tention that the older well-known districts at the other end of the developed territory at Cardin, Picher, and Century, in Oklahoma. All of the work so far consists of drill-prospecting, none of the shafts having yet penetrated into the ore-horizon. The drill-prospecting, however, reveals ore running from 80 ft. in depth to 160 ft., giving a thickness of 80 ft. of ore. The depth at which the ore is found varies from 80 to 160 ft. and has been found as deep as 235 ft. Cuttings run from 3½% in the poor holes, to as high as 35% in the better holes. There is sufficient prospecting work already done to demonstrate the existence of a large field, and the acreage taken up in leases is rapidly approaching an amount already existing in the Oklahoma part of the region. Some of the operators who have already made very rich strikes in their prospecting of leases are Thomas Coyne of Webb City, Missouri; Frank Dangle and associates of Webb City, Missouri; T. J. Franks of Joplin, Missouri; Newton Bros., of Miami, Oklahoma; Charles Windbigler and associates of Miami, Oklahoma; and the Acme Mining Co. of Carl Junction, Missouri. All of these concerns have made rich strikes, and there are a dozen or more new concerns drilling in the new field. With the activity now under way and the excitement already so great, it is believed there will be as extensive a drilling campaign in this field as in the Miami, Oklahoma, and Baxter Springs, Kansas, fields.

NEVADA

MINING LEGISLATION SOUGHT.—DEVELOPMENTS AT MANHATTAN AND GOLDFIELD.

Numerous bills of interest to mining men have been introduced in the present session of the legislature. One measure authorizing a bond issue of \$500,000 for construction of a State custom smelter aroused much interest and developed a tie vote in the assembly. Numerous complaints are being made to the legislators by small-mine operators to the effect that the smelters are charging excessive rates for handling of custom ore, or are refusing shipments. Most of the smelting companies are unable to handle all of their own ore, which probably accounts for the inability to accept small custom shipments.

Another bill has been introduced in the interest of the labor unions. It prohibits the courts from granting injunctions against striking miners, or from interference with them when seeking shorter hours or higher wages. Other measures pending relate to workmens' compensation, State aid for prospectors, and improved mine conditions. The high metal prices and increased dividends earned by numerous Nevadan companies have encouraged bills for higher mine taxation.

After lying dormant for practically ten years, Manhattan has again taken a prominent place among Nevadan camps, as a result of important developments on the 435-ft. level of the White Caps mine. Aside from the statement that the orebody averages around \$50 per ton the management is giving out little information, preferring to wait until further developments establish the dimensions of the orebody. Development has been resumed on the 300-ft. level. Equipment for the mill and roasting-plant is arriving, but it will be several weeks before the plant will be ready for service. The owners of the Morning Glory, adjoining the White Caps, have arranged to sink the shaft deeper in hopes of intersecting the White Caps vein-system. The mill of the Union Amlagamated has been placed in operation. There is 200 tons of ore on the dumps and arrangements are being made to draw ore from the 600-ft. level of the recently un-watered Bath shaft. The vein at this point is free-milling and 5 ft. wide. Assays are said to average around \$20 per ton. The Big Four, Manhattan Consolidated, Gold Wedge, and other companies are preparing for more work. Considerable placer mining is still being done in the neighboring gulches. Unusually heavy snow insures an active placer season.

George Wingfield, president of the Nevada Hills Mining Co., operating at Fairview, announces that the corporation is seeking another mine, as the ore possibilities of the Nevada Hills have been apparently exhausted. The quickly convertible assets are placed at approximately \$351,002, including \$70,734 in cash. Several properties have been presented for consideration. The company is advertising that leases on Nevada Hill ground may be secured on favorable terms.

Goldfield conditions are steadily improving. The Goldfield Consolidated Co. has started vigorous developments in the Laguna mine, with attention for the present chiefly confined to the 260-ft. level, at a point 440 ft. south of the shaft. A fair tonnage of \$10 ore is being sent to the mill from this level. Ore averaging \$14 to \$15 per ton is coming from the 450 and 600-ft. levels of the Mohawk. It is reported extensive work will be resumed shortly in the Grizzly Bear mine, adjoining the Atlanta group.

The Red King claim of the Florence-Goldfield group has been taken under lease by the Red Hills-Florence Co. The lease permits development to a depth of 650 ft., the area to be 1000 ft. long and 500 ft. wide. Work will be carried on from the 800-ft. Red Hill-Florence shaft. This shaft has been repaired to the 250-ft. level and three shifts of miners are continuing the work to the bottom level. An excellent plant has been installed.

The Orleans Mining & Milling Co. is shipping \$40 ore from its Hornsilver mine, in the Hornsilver district. On the 400-ft. level the vein is 6 ft. wide and is developing well. The company was recently reorganized with J. W. Dunfee, president and manager, and C. Terwilliger, secretary. A. H. Elftman is consulting engineer. The Silver Mines Corporation is grading for a 100-ton cyanide-plant and preparing to build an eight-mile water-line. The incline shaft has been straightened for a length of 300 ft. and will form the main working outlet.

The branch road of the Nevada Copper Belt Railway to the Bluestone mine has been completed, and ore shipments are going direct to the Mason Valley smelter. The plant is treating 750 tons of ore daily, the product coming from the Bluestone and Mason Valley mines.

TORONTO, CANADA

POTASH A BY-PRODUCT OF CEMENT-MAKING.—THE NICKEL QUESTION AGAIN.

Potash is being produced in commercial quantity in Ontario by the National Portland Cement Co., of Durham, which is turning out 12 to 16 tons per day, as a by-product of its cement output. This development, which is regarded as highly important, in view of the great demand for potash and the large quantity of the raw material, feldspar, that is available, is due to a series of experiments by Allen Grauel, who came to Canada from Pennsylvania three years ago, and since has been working out his process at the Durham plant. By addition of feldspar to the limestone used in the cement manufacture, the quantity of potash escaping with the fumes was largely increased, and a process was perfected by which it could be collected. The plant is now producing 2000 tons of cement daily, on which basis the output of potash would be 15 tons. Both muriates and caustic potash are produced, and it is claimed that the former is almost pure. Additional installations are being made which will increase the potash output to 20 tons per day. Although feldspar deposits abound throughout Ontario and Quebec and development began about 1890, the industry has languished for want of a convenient and profitable market. The highest yearly output was in 1914 when 18,060 tons was produced. Practically all the Canadian output is consigned to American potteries, the cost of freight preventing the profitable working of all except a few deposits within easy access of the border. Now that a home market has been opened a rapid development of the feldspar resources may be looked for.

Since the opening of the Ontario Legislature last month the politicians have been at it, hammer and tongs, over the nickel question, which has now become almost entirely a party issue, most of the recalcitrant conservatives, who were disposed to object to the Government policy, having professed themselves satisfied with the assurances that existing arrangements have the sanction of the British War Office. On February 21 a resolution (supported by the opposition) to the effect that all nickel mined in Ontario should be refined wholly within the British Empire and that the Province should own and operate a refining-plant was defeated by a vote of 59 to 26—a strictly party division. The opposition makes a strong point of the light taxation levied by the Government on the operations of the International Nickel Co., under the agreement, made some time since, for a flat rate of \$40,000 per year, which it is contended is many times too low, in view of the great expansion of the company's business caused by the War. The Government has promised a revision of its arrangement, but when challenged as to its policy replies that it will be guided by the long-delayed report of the Nickel Commission, the appearance of which has been retarded by the illness of the chairman, G. T. Holloway. Some surprise was created during a recent debate by the statement of Attorney-General Lucas that at the outset of the War the International company had offered to give the Canadian Government the entire control of its output, which is regarded as an effective answer to the accusation that the company is under German influence. Nothing has been heard recently of the project of the British America Nickel Co. for the construction of a refinery, but it is understood that they are experiencing some difficulty in selecting a suitable site where they can obtain the large supply of electricity that they will require. Owing to industrial expansion, more especially as regards the manufacturing of munitions, the demands of the localities served by the Provincial Hydro-Electric Commission with power generated at Niagara Falls have so greatly increased that extensive additions to the system are being undertaken, and in the meantime the plans of the British America company will, as a consequence, be held in abeyance.

The first annual report of the Hollinger Consolidated shows a production of \$5,073,401, the number of tons hoisted being 604,062. Profits from the operations were \$2,866,964, and premiums on shares sold \$180,000. The net income after deductions for taxes and depreciation was \$2,856,409. Dividends amounting to \$3,126,000 were paid, leaving a deficit of \$269,590. Working-costs were \$4.03 per ton as compared with \$3.98 in 1915. Additions to plant and development cost \$599,417. Actual ore reserves on December 31 were estimated at \$34,185,535 as compared with \$33,837,870 at the end of 1915. The four-weekly statement for the period ended January 28 showed a further increase of the deficit to \$298,490. The gross profits were \$217,000 from the treatment of 48,119 tons of ore of the average value of \$8.71 per ton, at a working-cost of \$3.88 per ton. The mill ran 85.5% of the possible running-time.

The Dome Mines during February produced bullion to the amount of approximately \$172,000 from the treatment of 36,400 tons of ore of the average value of \$4.75 per ton at a cost of \$2.88 per ton. The new Hardinge ball-mill now in course of installation is expected to be complete in a few weeks, bringing up the tonnage to about 55,000 per month. Production at this mine, as elsewhere, has been much curtailed by the labor shortage. It is understood that the forthcoming annual report will show that development at depth has much improved the average grade of the ore. Electric power has replaced steam at the West Dome Consolidated and has been found much more economical. Driving on the main vein for a distance of 500 ft. on the 300-ft. level shows that the average width of five feet is maintained. Assays show considerable variation, but the average gold content for the whole width of the vein is \$12 per ton.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ARIZONA

GILA COUNTY

(Special Correspondence.)—The Christmas mine, at Christmas, is the property of the Gila Copper Sulphide Co., and not of the American Smelting & Refining Co., as stated in the issue of the MINING AND SCIENTIFIC PRESS of February 24. Moreover, the tonnage capacity per hour of the aerial tramway at this mine was also under-rated.

Christmas, March 9.

MOJAVE COUNTY

(Special Correspondence.)—OATMAN. Shipments of bullion were made the first week of March from the Tom Reed and the United Eastern mines. The amount of the Tom Reed shipment was not given out but is unofficially reported to have been \$60,000, for the month of February. The United Eastern shipment contained approximately 5800 oz., troy, valued at about \$72,000, making a total for February of about \$145,000 from this mine.—The Big Jim and Tom Reed have developed the Big Jim-Aztec orebody for approximately 1800 ft. About 400 ft. intervenes between the headings of the two mines on the 400-ft. level with both faces in ore. The average of the Big Jim is \$20.67 on the 400-ft. level and \$58.60 on the 500-ft. level. The Tom Reed has been in ore for the past 100 ft., said to average \$50 a ton. Some very rich specimens have been extracted.—Preliminary flotation-tests on ore from the Gold Ore mine resulted in a concentrate of 30 into 1 with an extraction of 95%. The tests were conducted at the San Francisco laboratory of Minerals Separation Co., Ltd. Further tests are to be conducted.—The fiscal year of the Tom Reed Gold Mines Co. ends March 31. The new management took charge in April, 1916, and has done much development work in the eastern end of the company's property, resulting in opening a large body of ore of good milling grade containing streaks of rich ore. The vein is 30 ft. wide and the entire vein filling is ore of a milling grade. The company is constructing a 150-ton addition to its cyanide-mill. Marcy ball-mills will be used for crushing and pebble ball-mills for fine-grinding.

Oatman, March 14.

PIMA COUNTY

(Special Correspondence.)—The Ray Hercules Mining Co. is to build a 2000-ton concentration plant at Ray. This property is in the centre of the Ray district and has a large body of ore developed. This ore is an extension of the Ray Consolidated orebody, which was displaced by a fault, with a 350-ft. drop. The original plan was for a mill of 1000 tons daily capacity, but the plans have been enlarged.

Ray, March 14.

(Special Correspondence.)—A strike was made on the Copper King group of the Mile Wide Copper Co., the last week in February where extensive chalcopryrite was encountered at the 200-ft. level. After cross-cutting the orebody at the 200-ft. level 16 ft. and 4 in., the cross-cut was continued 20 ft. farther to a parallel orebody of chalcopryrite. Superintendent Visel states that it will average better than 30% copper. Development to date shows it to be 8 ft. wide. As far as developed it has no connection with the previously developed orebodies, being a parallel vein. It is the opinion of the management that the new strike will ultimately join the 16-ft. vein being developed since last December.

Tucson, March 12.

SANTA CRUZ COUNTY

NOGALES. A. C. Mowbray and A. C. Wright have taken a bond and lease on the Rosario mines in the Santa Rita mountains, not far from the Salero property. There is a 6 ft. vein developed by an adit, from which there has been taken a great deal of good ore. Some of the samples ran 51% lead, with a good showing in silver. Other samples showed a high percentage of zinc.

Near the upper end of the Montosa canyon, in the Santa Rita mountains, on the west side, the Santa Cruz-Bisbee Co., J. L. Walker, manager, is reported to have made recently a strike of high-grade ore, at the end of a 300-ft. tunnel, which has cross-cut a ledge 10 ft. wide, with ore yielding lead, zinc, gold, and silver. The vein was cut at a depth of 300 ft. below the crop-pings. Another tunnel is being driven, and it will go 1000 ft. before reaching the vein which it will cut much lower.

YAVAPAI COUNTY

PRESCOTT. At the Mint mine, three miles west from Copper Basin, the shaft is 200 ft. in depth, and the timbering is being re-placed. This part of the work will soon be completed. In the meantime the engine is being placed upon a new concrete foundation. The first new work will be the driving of a 100 ft. cross-cut at a depth of 200 ft. Work done some years ago, when the Mint was classified as a gold mine, showed the existence of copper ore of good grade, and the cross-cut will be run with a view to determining the extent of the copper ore.

The camp in Copper Basin of the Arizona-Portland Mining Co. is now thoroughly equipped with modern appliances for shaft sinking, and the sinking of the shaft to at least 500 ft. will go forward rapidly. A new hoist, compressor, pump, three jack-hammers, and a dreadnaught, with all minor appliances, are now at the mine and in a few days will be ready for work. The shaft is 140 ft. deep.

Plans are being made to resume operations at the Tus-cumbia mine, in the Crown King district, and owned by the Tus-cumbia Mining & Milling Co. of Arizona, and has a production record of approximately \$500,000, the ore is coming from four adits to a depth of 300 ft., and in the shoots carrying as high as 1000 oz. silver to the ton. The property is under option to a Nevada and Californian mining and oil man. Work will begin April 1, contingent upon the state of the roads and weather at that time.

Geological and mineralogical conditions suggest that the ore-body recently discovered at shallow depth in the Calumet & Jerome workings is a continuation of the deposit encountered at a similar depth in the United Verde extension workings during the early stage of development there. The ore was opened in Calumet & Jerome ground near the line of the United Verde Extension property and is identical in appearance with the ore exposed in the upper workings of the last mentioned. It samples as high as 12% copper and carries an average copper content of 4 per cent.

The Foreshoulder group of claims has been purchased by A. B. Rombauer, of Butte, Montana, and others. The acreage is situated in the Walker basin near the Pine Mountain property and has considerable prospective value. The former owner, Jersey McCloud, sunk a shaft 85 ft. and opened a body of gold-silver ore. It was this showing that decided Rombauer to buy the property. The latter will equip the shaft with machinery and will sink it to a depth of 200 ft. before cross-cutting the formation.

The sale of the Foreshoulder group, following so quickly the sale of the old Homestead property to the United States Continental Mines Co., of New York City, has stimulated interest in the mines at Walker basin. Four extensive properties are now being worked there and another will become active the current month.

CALIFORNIA

F. M. Hamilton, State Mineralogist, announces that the first annual report, covering the work of the State Mining Bureau in protecting Californian oil-fields from infiltrating water, has been published and is ready for distribution. There is about \$250,000,000 invested in the Californian oil business, and during the past fiscal year about \$6,000,000 was expended in drilling new wells, and it is unnecessary to more than call public attention to the insignificantly small amount of money necessary for the protection of the investment. The reports of oil-field work made to the State Mining Bureau for the week ended March 10, 1917, show 18 new wells started, 29 to be inspected for test of water shut-off, 12 deepening or re-drilling, and 5 to be abandoned.

BUTTE COUNTY

OROVILLE. It is reported that numerous transfers of mining property in the eastern part of this county near Forest-town, and also some mines in Plumas county, near La Porte, have recently been taken under option by Eastern men, who propose to develop them and equip them with machinery. The properties referred to are mostly low-grade, with a great deal of ore available.

C. L. Salmon has bonded his quartz mine at Badger Hill, a mile from Cherokee, to the California Extraction Co. Kay & Elliott are members of the company and they have other mining interests in this county. Last summer they erected a plant to work a portion of the bottom of the South Yuba river, above Edwards crossing. The Salmon mine has a shaft 100 ft. deep on the vein and some fine ore was extracted when the property was operated by the Salmon brothers. Included in the surface equipment is a 4-stamp mill, which was in operation a few years ago. The bonding company will start active work of development in 60 days, or as soon as the roads are in shape for hauling in supplies.

EL DORADO COUNTY

PLACERVILLE. Frank Everett has bought the Cambrian mine near Coloma, and will begin the work of development.

NEVADA COUNTY

NEVADA CITY. The lower levels of the Champion-Providence mines are flooded because of the breaking of the large electrically driven pump that handles the water in those mines. The pump can only be repaired by a new casting, which will be provided as soon as practicable. Meanwhile, work will be continued above the 2700-ft. level. It is thought the pump will be in working condition again before the water reaches the 2700-ft. level.—The work on the addition to the Golden Center mill is nearly completed. All the machinery is in position and it is thought by the first of next week the ten new stamps will be pounding away daily. Manager Charles Brockington stated last night that the work only awaits the arrival of the concentrator belts and then the mill will be started immediately.—What is believed to be one of the most important strikes made in the Grass Valley-Nevada City district for a number of years is reported in the Pittsburg mine at Gold Flat, near Nevada City. While running a long drift at 1300 ft. depth, quartz was struck which is believed to be the long-sought Gold Flat-Potosi vein, which yielded several fortunes in former days and at less depth. The ore is not free milling, making it necessary to ship to smelters for treatment.

WASHINGTON. It is reported that the Eagle Bird mine, an old producer, six miles east of Washington, is to be re-opened. William Wilson of Marysville is the owner and he has inter-

ested capital in re-developing the property. A new mill and blacksmith shop have been erected.

PLUMAS COUNTY

(Special Correspondence.)—Grading of the Indian Valley railroad has been completed to the lower camp at the Engels mine, and rails are laid to three miles beyond Vermont. Heavy snow is hampering work but the company expects to be in a position to handle ore and freight between Keddle and the mine by April 15.

The Spreckles interests of San Francisco have acquired control of the Engels mine and are preparing for more extensive work. John Reinmiller has been appointed general manager, and grading for the two new flotation-units is progressing. Each unit will have a capacity of 500 tons daily, and the first is scheduled to be ready by July 1.

The U. S. Smelting, Refining & Mining Co. has placed a compressor at the Iron Dike mine and has 20 men working. The orebody is stated to be 12 ft. wide and of good grade. In the Five Bears group the orebody is 55 ft. wide and of excellent grade. There are 20 men at work and it is reported 40 more will be added. The company is also working the Eagle Hill and other claims between the Engels and Walker properties.

The United States Exploration Co. is planning the building of a mill and power plant at its property near Granite mountain. A strong vein of gold-bearing quartz has been opened at a depth of 300 ft., according to news from the mine.

Electrically operated pumps and a hoist have been installed at the Crescent gold mines, near Crescent Mills, and a transmission-line built to the property by the Great Western Co. Unwatering of the shaft will start within a few days.

Portola, March 19.

SHASTA COUNTY

REDDING. The Arps group of copper mines near Copper City has been sold. Included in the deal is the Reno group of mines adjoining. The Arps group was owned by R. M. Saeltzer and Antone Jaegel of Redding and William Arps of Copper City. Arps located the mines and spent years in developing them. Joseph Kahny of Redding also owned an interest. The purchasers are San Francisco and Oakland men who have formed a corporation known as the Arps Copper company.

The Arps group was bonded last August. The bonders made two shipments of copper-silver ore to the Kennett smelter. The returns were so satisfactory, they concluded to pay the money and take the group. Sixteen men are at work in the Arps mines. Superintendent Henry says the company plans to put up some sort of reduction works—a flotation plant, perhaps, but that at present ore will be shipped to the smelter.

The newly financed Afterthought Copper company is preparing for a heavy output from its mines at Ingot. Repairs to the main adits have been completed and car-tracks and bridges are being overhauled.

The Mammoth Copper Co. has installed an electric hoist and pump at the Donkey copper mine, near Ingot, and has unwatered the shaft and is sinking and driving on a deposit of copper ore.

The Mountain Copper Co. is making the heaviest copper output in its history since the closing of the old Keswick plant. The capacity of the Minnesota flotation-plant has been practically doubled, and a heavily increased output of ore and concentrate is being forwarded to the Martinez smelter.

Arrangements are being made for more vigorous work at the Michigan, Shasta-Belmont and other properties lying near the Bully Hill and Arps groups. The Shasta-Belmont directors are considering the advisability of erecting a small flotation-plant.

SIMS. The first carload of chrome from a mine opened near Sims less than a month ago was shipped this week to Cleveland, Ohio.

Twelve men are employed by the American Manganese Co.

on its manganese claims on Duncan creek, west of Ono. Eighteen miles of road will be constructed before ore can be shipped to the smelter at Heroult. Two tunnels are being driven into the orebody.

SIERRA COUNTY

ALLEGHANY. Paul Proper of Oakland, has purchased a one-fourth interest in the Kanaka mining claim, owned by Ambrose Madden. A tunnel has been driven 300 feet.

DOWNIEVILLE. The pay-shoot on the Oro vein at Downieville, was found by driving a cross-cut from the drift to the vein last week. The shoot dips to the north and the gouge on the walls, as well as the crushed quartz, pans free gold. The vein is 4 ft. wide where the shoot was found. A drift will be run to determine the length of the shoot, and subsequently the lower or No. 3 adit will be continued on to the vein, a distance of 150 ft. east, which would give 500 ft. of backs. The property is being developed by Dr. Reynolds and associates of Alameda under a bond, and is now under the charge of John Costa.

Several small snowslides have come down through the Keystone ravine, below Sierra City, says the *Messenger*. The boarding-house of the Keystone mine is said to be smashed and the mill damaged to some extent. The Keystone ravine is noted for its slides and at times everybody moves from the mine.

A contract is to be let to extend the tunnel at the Wide Awake gravel property at least 100 ft. farther toward the channel, and several parties are figuring on putting in bids for the work. The matter will be definitely decided when Thomas Wilson, who has the property under bond, returns.

SISKIYOU COUNTY

Lottie A. Bell of Etna Mills has applied to the State Water Commission for permission to approximate 12½ cu. ft. of water per second from Taylor creek, tributary to the east fork of Salmon river for mining purposes. The details of the proposed works are not given.

TULARE COUNTY

(Special Correspondence.)—The incorporation and property of the California Talc & Soapstone Corporation, which operated for a number of years in Tulare county, but has been inactive for several years owing to lack of raw material, has been taken over by a new company composed of W. A. Saylor and A. T. Wood of Oakdale, and G. W. Brown, George D. Avery, and Omar Avery, of Porterville. The new company has under lease 600 acres about a mile north-east of Porterville, on which there are extensive deposits of talc of a fine grade, much of which has but recently been discovered, some of it by accident, as in the case of the drilling of a well when a mass 100 ft. in depth was discovered. Some of the talc is almost pure, containing less than 0.25% of iron and less than 1% lime. Twenty men will be put to work on the deposits, and the talc will be hauled to the railroad and shipped to the mill at Lindsay, that was formerly operated by the other company, but has been closed for the past several years. Later when the Santa Fe Railroad builds into this community it will run near the property and they have agreed to run a spur-track to a convenient location where a new mill will be built.

Boydston brothers, owners of extensive orange groves in the vicinity of Porterville, now have in operation their new agricultural lime-mill situated on the P. & N. E. railroad, about 5 miles east of Porterville. The mill has a present capacity of 70 tons per day, which with added equipment contemplated, can be raised to 150 tons daily. The latest type of machinery is used throughout the mill. A force of 30 men is employed at the mill and mine, two miles distant. Miners have been at work in the mine for several months taking out sufficient rock to get the plant started. Hitherto all the lime for use in orchards and otherwise has been shipped into central California from the northern and southern parts of the State, so

that a lime-mill in the central part of the State will mean a considerable saving in freight to users of lime in that section. Porterville, March 14.

TUOLUMNE COUNTY

(Special Correspondence.)—The sudden and unexpected suspension of operations at the Dutch-App mine a few days ago has given rise to much speculation in local mining circles. However, the prevailing belief is that work was stopped to enable carrying out the plans lately adopted for extensive changes in the plant, the capacity of which will, by the improvements contemplated, be increased to 18,000 tons of ore per month. W. J. Loring, head of the company, is at present not in the county, and likely not before his return will it be known just what is to be done at the property.

Twenty tons of ore is milled daily at the McCormick mine, north of Jacksonville. Ten men are employed and an assay office has just been erected. The mine is worked through an adit 1500 ft. long.

A steam-hoist, an air-compressor and other machinery purchased from the Street mine, at Tuttletown, are being hauled to the magnesite mine near Chinese Camp that is being operated by Eugene Schmitz and associates, of San Francisco. Buildings to accommodate the working force and machinery are being erected.

Sonora, March 10.

COLORADO

LAKE COUNTY

LEADVILLE. Development in the Down Town section is increasing. This territory which was closed to activity up to two years ago by an enormous flow of water that flooded the greater part of the old workings is now open to operations and is being exploited by six properties, says the *Chronicle*.

At the Penrose, the scene of the pumping that drained the area and where the plant installed continues to handle the water, several large and important ore-shoots have been opened. Enormous bodies of manganese have been uncovered in the upper workings and a steady tonnage of the ore is being extracted. Prospecting drifts that are being driven into new territory on several levels have exposed large bodies of zinc and lead carbonate. Development in these new discoveries is still under way and the extent of the ore deposits has not been ascertained. Trial shipments of the zinc carbonate have been made showing the ore to contain on an average of 25% zinc.

Recently the tonnage from the property has been curtailed by a shortage of railroad cars, a trouble that has been experienced throughout the winter. Because of the inability to secure the necessary cars, no effort is being made at present to increase the production from the property. Contracts for manganese are being filled and the other ores are being held for shipment later when more favorable conditions will prevail.

The pumps continue to throw 1800 gal. of water per minute, which appears to be the normal flow in the Penrose and surrounding territory.

At the Home Extension and Cloud City properties the development of the large manganese bodies that have been opened is progressing and a heavy tonnage of the ore is being produced. Considerable prospecting is also being done which promises to uncover new deposits.

IDAHO

SHOSHONE COUNTY

The Mammoth mill, which has been undergoing extensive changes during the past few months, is now practically a new mill and is running at capacity on ore from the Morning mine. Numerous changes and many additions were made, including a large flotation-plant. The capacity of the mill was also increased from 450 to 500 tons per day, which added to the capacity of the Morning mill gives a total milling capacity

of 2000 tons per day. The Mammoth mill is now one of the most modern and complete in the district.

The force at the Jack Waite mine has been increased to 35 men, and an additional team has been put on the road hauling ore, making three teams. Each team hauls from 4 to 5 tons at a load. The distance hauled is 10 miles and last month snow-slides seriously interfered with hauling. The mine is reported in fine condition, and shipments are netting the company a substantial surplus after paying all operating expenses which will be sufficient, it is expected, to build a mill as soon as the snow will permit outside work.

MICHIGAN

HOUGHTON COUNTY

CALUMET. This is going to be a year of enormous construction work among the copper mining companies of this region and millions will be spent in the erection of new plants, additions and auxiliaries to old plants, and in the extension of mining and milling work in every direction says the *Boston News Bureau*. The Calumet & Hecla and its subsidiary companies will lead in these enormous expenditures.

Structural work is to be carried on at the Isle Royale, Ah-meek, and other subsidiary mines, at the big reduction and copper extraction plants of the Calumet & Hecla at Lake Linden, Hubbell and elsewhere. A dozen or more of the mining companies will erect scores of new residences and boarding houses for their employees, as well as clubhouses and social centres. Concrete and steel will enter into the new construction work this year on a scale never before attempted.

One of the biggest pieces of work to be undertaken by Calumet & Hecla will be the erection of the large new coal-derricks or aerial tramways at Hubbell, where the big supplies of Calumet & Hecla fuel are received. Two bridges, capable of handling 21 tons of coal per minute from boat to dock, will be put up. The largest coal carrier can be unloaded through use of these bridges, in six to eight hours, thus gaining considerable time in a single season in getting back down the lakes after new cargoes.

The Calumet & Hecla and associated corporations also this year will lay in the greatest supplies of fuel ever brought to the district, probably something over a million tons. The Hubbell docks are to have a capacity of 500,000 tons, in addition to 300,000 tons at the Dollar Bay docks, the big capacity of the Isle Royale fuel yards, and the Point Mills plants. At present enormous consignments of coal are coming in by rail from Milwaukee and other points.

The Isle Royale Mining Co. will this summer erect four modern changing-houses, each 42 by 96 ft. They will be of steel frame construction with concrete walls and fireproof roofs. The company is now erecting a temporary wooden rock-house at No. 7 shaft.

HOUGHTON. The annual report of the Osceola Copper Co. shows that the cost of producing copper in 1916 was 11.69c. per pound, which was an increase of 16% over the cost in 1915. The recovery of copper per ton of rock in 1916 showed a slight improvement and amounted to 15.2 lb. Notwithstanding this comparatively low yield, the company succeeded, as above stated, in showing earnings of almost \$29 per share, in spite of all the increased costs of doing business. It was an achievement which bears striking testimony to the manner in which the low capitalized properties of Lake Superior are able rapidly to increase share earnings on a high metal market.

It has been reported at the office of the Mass Consolidated Mining Co. that the Evergreen lode has been struck on the 7th level, 360 ft. from the Butler lode and that the strike looks rich. The company has just sold a lot of copper for nearby delivery at 36½c. per lb. cash.

The Calumet & Hecla runs its No. 2 re-grinding mill, which handles the sand or tailing dredged from the Lake, on Sundays from noon on. This might be called a gold mine says the *Keweenaw Miner*, as the copper recovered here that is being

sold for over 30c. only costs a little over 4c., and then there is more copper recovered from the slime at the leaching-plant. The dredge has not lost a minute during the whole winter by reason of being blocked by ice, as a special small gang devotes its time to this work.

MONTANA

SILVERBOW COUNTY

The pay-roll of the Butte district, including miners, clerical help, public service corporation's employees, and others, for the month of February amounted to \$3,500,000. The Anaconda Copper Mining Co. for its clerical force alone had a pay-roll of \$41,830 for February, which was the shortest month of the year. When this is added to the \$1,596,352 paid to the miners, it means that the Anaconda Copper Mining Co.'s pay-roll for the shortest month of the year will total \$1,638,182 for Butte alone.

In addition to the figures the following were obtained as the pay-roll for February: East Butte Copper Mining Co., \$146,700; Elm Orlu Mining Co., \$50,000; Timber Butte Mining Co., \$25,000; Butte-Ballaklava Copper Co., \$7014.

It is estimated that the public service corporations, the corporations other than mining and the business houses paid out approximately \$1,000,000 in wages for last month, which will make the total pay-roll for Butte amount to \$3,500,000.

When one considers that Butte has at present a population of 110,000, it means that the mines alone pay what amounts to an average of about \$24 a month for every man, woman and child in the mining city.

There are few cities of three and four times the population of Butte which have a pay-roll of such magnitude, and when one considers that the wages paid at present are \$4.75 a day of eight hours and that most of the money received in wages is spent in the city, there is little surprise at the class of goods which the residents of this city demand and which the merchants of Butte carry in stock.

NEVADA

NYE COUNTY

MANHATTAN. Manhattan district is attracting renewed interest by reason of the rich development in the White Caps mine, just below the town of Manhattan. Concerning this the *Tonopah Times* says: The east drift on the orebody at the 425-ft. level in the White Caps is now out 50 ft. and a cross-cut has been started south in the face of this drift. This cross-cut is now in 6 ft. and is to be extended to the hanging wall. The management expects to resume operations in the south drift. A drift has already been started from the cross-cut. A grab sample from the first round of shots returned an assay of \$76.40 per ton.

It is expected that the west orebody will be encountered in the west cross-cut in about two weeks. Two cars of machinery are now in Tonopah awaiting shipment to Manhattan. One part, weighing 13 tons, will be taken over as soon as the roads will permit of heavy hauling again. A 16-horse team will be required to haul this part to the mine. Four more cars of equipment for the mill are expected to arrive here this week. This will complete the shipment for milling purposes, the arrival of which was delayed for several weeks.

NEW MEXICO

GRANT COUNTY

(Special Correspondence.)—Perry Crawford is mining a large quantity of manganese from his property, a city lot at Silver City, and shipping the ore to Denver.—The Grant Copper Co. will place machinery for the development of a mine it owns near Silver City. Roy H. Jones, of El Paso, Texas, is interested.—The Hanover Bessemer Iron & Copper Co. at Hanover, will re-build its milling and power-plant that was recently destroyed by fire, involving a loss of \$100,000.

Silver City, March 13.

QUAY COUNTY

TUCUMCARI. The discovery of tin in the ores of the Red Peaks Copper Co.'s mine is announced by D. E. Thomas, the superintendent. These mines are near Tucumcari, in the eastern part of the State.

SOCORRO COUNTY

(Special Correspondence.)—W. Rowland Cox, consulting engineer for Socorro Mining & Milling Co., made a brief visit of inspection of the company's properties the past week. For the last half of February, the plant produced 13 bars of gold and silver bullion.—At the Pacific mine, development is being pushed on two of the lower levels. The greater part of the old ore dump, accumulated during the past five years, has been transported to the terminal of the aerial tramway and hauled by the latter to the Socorro's mill for treatment.

The Mogollon Mines Co., operating the Last Chance mine, shipped 13 bars gold and silver bullion and several tons of concentrate for the latter half of February.—The Oaks company is doing development work on the Eberle, Clifton, and Maud S. properties, a contiguous group which, from both a geographical and geological view-point, promises to be one of the most important factors in the immediate future operations of the district.

Developments on the Bearup group north of Cooney are encouraging, with 3 ft. of mill-ore in the face of the tunnel now in 70 ft.—On the Mitchell group, in the same part of the district, a cross-cut tunnel has encountered 2 ft. of mill-ore.—Driving continues in the main adit of the Gold Dust properties in the southern part of the camp. The heading is expected soon to cut the orebody opened in the upper levels.—The best driving record for this district was recently made at the Last Chance mine by the Mogollon Mines Co., when the 900-ft. level was advanced 12 ft. in 24 hours.—The Oaks company has started work on the Maud S. mine.

Mogollon, March 6.

UTAH

TOOELE COUNTY

FERBER. There is a new town on the map in Utah—Ferber. A short time ago Ferber existed merely as a town-plot on paper. Today, according to the *Salt Lake Tribune*, Ferber is a real town with a boarding-house which accommodates 40 men; two portable houses, and a number of framed tents. It has one distinctive advantage—it is easy of access. A daily auto-stage and mail-service from Wendover to Ferber has already been established by Stroat brothers, the 40 miles between the two points being covered with regularity and without difficulty. Ferber will probably be the principal town of the Deep Creek mining region for some time to come. The recent completion of the railroad into the district has given a decided impetus to mining throughout the Deep Creek region.

MEXICO

A renewal of mining and smelting operations in northern Mexico is becoming general.

American Smelting & Refining Co.'s large smelter at Monterrey recently re-opened. Simon Guggenheim and Edgar Newhouse, with C. L. Baker, general manager of the company's southern department, are arranging for re-opening the Matehuala smelter in the State of San Luis Potosi.

The company plans to operate its own trains between Laredo, Texas, and Monterrey, for transportation of coke and other supplies, and to carry bullion from the smelter to the border. The de facto government has promised to exercise unusual vigilance in keeping the railroad open so that smelter operations will not be hampered.

Mazapil Copper & Mining Co., composed of American interests, has resumed operation of its smelter and mines at Concepcion del Oro, in the State of Zacatecas.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

JOHN P. MILLIKEN, of Colorado Springs, is here.

L. P. SHACKELFORD is returning from Washington to Juneau, Alaska.

JOHN REINMILLER is now general manager of the Engels copper mine.

C. C. BROADWATER has returned to San Francisco from Park City, Utah.

DONALD F. IRVIN is sailing from New Orleans this month for South America via Panama.

CHARLES E. VAN BARNEVELD, of the U. S. Bureau of Mines, was in San Francisco last week.

L. N. B. BULLUCK, formerly at Mexico City, has been promoted to major in the Canadian Engineers.

ARTHUR H. COLLEBAN sailed from San Francisco on March 20 on his way to Yokohama and thence to Korea.

ALF WELHAVEN, general manager for the Oriental Consolidated Mining Co., at Unsan, Korea, was in San Francisco.

MAURICE CLARK, representing the Exploration Company of New York, is in Calaveras county, California, and will go to Oregon shortly.

W. J. GRUSS has resigned as mill-superintendent for the Engels Copper M. Co. and is now in San Francisco. He will soon leave for Arizona.

H. H. NICHOLSON has made an examination of the Black Bear mine at Grass Valley, and has returned to the Plinco mine at Doyle, California.

HENRY C. CARLISLE has been appointed superintendent for the Mandy Mining Co., a subsidiary of the Tonopah Mining Co. of Nevada, with headquarters at The Pas, Manitoba, Canada.

ARTHUR E. WELLS, in charge of the Salt Lake station of the U. S. Bureau of Mines, is inspecting the Cottrell plants in company with W. C. CAPRON and J. K. MURPHY of the Anaconda company.

THOMAS VARLEY, metallurgist for the Federal Lead Co. at Flat River, Missouri, for the past five years, has resigned to accept the same position with the U. S. Bureau of Mines at the new station at Moscow, Idaho, to be established in connection with the University of Idaho.

Obituary

MARK B. KERR died at his home in Berkeley, California, on March 15, at the age of 59. He returned very ill from Salvador a few days before. He was an engineer of wide experience and high character. Early in his career he worked on the topographic branch of the U. S. Geological Survey and during later years he was connected professionally as manager or consulting engineer, with a number of well-known mines, such as the W. Y. O. D. at Grass Valley, the Paloma in Calaveras county, the Jumper, in Tuolumne, and the Montana Tonopah and West End, at Tonopah, Nevada.

A TOPOGRAPHIC MAP of Washington, D. C., and vicinity by the United States Geological Survey is now ready for distribution. The new map is the result of recently completed topographic surveys, and is a typical example of the best art of map-making as refined and developed by the Geological Survey. The map was drawn in the field by the topographic engineers of the Survey. It shows an area of 465 square miles, including almost every form of topography, from the lowlands along the Potomac Drive to the broken country in Rock Creek Park and the picturesque gorge of the Potomac above the city. It is sold by the Geological Survey at 25c. per copy.

THE METAL MARKET

METAL PRICES

San Francisco, March 20

Antimony, cents per pound	24
Electrolytic copper, cents per pound	38
Pig lead, cents per pound	9.50—10.50
Platinum, soft and hard metal, per ounce	\$105—111
Quicksilver, per flask of 75 lb.	\$115
Spelter, cents per pound	13
Tin, cents per pound	50
Zinc-dust, cents per pound	18—20

ORE PRICES

San Francisco, March 20

Antimony, 50% metal, per unit	\$2 00
Chrome, 40% and over, f.o.b. ears California, per ton	18.00—20.00
Magnetite, crude, per ton	8.00—10.00
Tungsten, 60% WO ₃ , per unit	17.00—17.50
Molybdenite, per unit for MoS ₂ contained	40.00
Manganese, 50% (under 35% metal not desired)	29.00
Manganese ore, 40 to 45%, sells f.o.b. Chicago at 58c. per unit with a penalty of 50c. per unit for more than 8% silica.	

EASTERN METAL MARKET

(By wire from New York)

March 20—Copper is dull and easier. Spot lead is lower at 9.75 to 10c., the market conditions remain practically unchanged. Zinc is lower, with a stagnant market.

SILVER

Below are given the average New York quotations, in cents per ounce of fine silver.

The Old Dominion Copper Co. has declared a quarterly dividend of \$3 per share, payable March 30 to stock of record March 14.

Old Dominion paid \$3.50 three months and \$3 six months ago.

Since 1905 Old Dominion has paid dividends aggregating \$40 per share.

The Old Dominion Company of New Jersey declared a dividend of \$3.50 and the United Globe Mines a dividend of \$22 per share.

Value of 1361 tons of concentrate resulting from flotation operations during February at the Miami Copper Co. plant was \$265,766 against \$318,628 derived from production of 1553 tons of concentrates in January.

A comparison of the monthly statements which Miami makes in connection with its flotation operations follows:

	Feb.	Jan.	Dec.
Tons feed	113,639	124,676	121,493
Tons concentrates	1,361	1,553	1,480
Assay:	%	%	%
Copper in feed	1.180	1.175	1.118
Copper in concentrate	43.426	43.059	41.521
Copper in tailing	0.668	0.646	0.620

Not for another month do Miami interests look for a decision from the United States Circuit Court of Appeals on the company's recent appeal from decision of the United States District Court in the suit brought against it by Minerals Separation company.

ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound.

ALUMINUM

Quotations remain unchanged at 57 to 59c. for No. 1 virgin aluminum, 98 to 99% pure. The market is quiet.

ANTIMONY

The spot market continues quiet at 31c. per lb., nominal, for Chinese and Japanese goods. Spot metal is very difficult to obtain, however. As high as 32c. was asked yesterday. Sellers seem anxious to come to an understanding with buyers as to future deliveries even to the extent of shading. Metal shipped from China and Japan in February is quoted at 18.25c. in bond with March shipments at 15.50c. Sellers are asking about 29c. for delivery in two weeks. If the Government buys ammunition on a large scale as a result of war, prices are expected to advance.

ORES

Tungsten: The market is active with foreign demand the feature. There has been buying by both foreign or domestic consumers with high-class concentrate selling at \$17 to \$17.50 per unit. A domestic user of ferro-tungsten has recently made a large purchase. The present quotation is about \$2 per lb. of contained tungsten.

Molybdenum: Ore deliveries are unsatisfactory, which handicaps the producers of ferro-molybdenum. It is stated that wulfenite has been sold at \$2 per lb. contained molybdenum. In the opinion of one dealer molybdenite, if readily available, would probably bring the same price per pound of MoS₂ contained.

Antimony: Prices are a little easier at \$2 to \$2.25 per unit but shipping conditions from South America make business very difficult.

The demand for spot antimony is still not quite as pressing and prices range nominally 31c. The forward antimony market has become practically stagnant and March-April shipment is quoted at 14 1/2 to 15 1/2 c. in bond. In need antimony further business has been done in large quantities at 9 1/2 c. for March-April shipment from the Far East. The conditions of shipment from South America make business in antimony ore almost impossible.

Eastern Metal Market

New York, March 14.

The entire metal market is a waiting one, both buyers and sellers doing as little as possible until conditions become more settled, both external and internal.

Copper was unchanged until yesterday, when it became a little easier and lower.

Zinc is stagnant with very little being sold. In fact the market is abnormal, as it should normally be more active at this season.

Lead was quite a little easier yesterday because of large arrivals from the West.

Anxiety in the tin market has abated considerably so that yesterday it eased off 1c. per lb. for spot metal to 53 cents.

Spot antimony is hard to get at the nominal quotation of 31 to 32 cents.

The pig-iron market continues to go higher and at advances that are from two to four times the usual ranges. Basic iron has sold up to nearly \$34, delivered. Foundry irons are generally \$1 to \$2 higher than a week ago and Bessemer iron for the last half is \$1 to \$2 above the prices of a week ago. The Steel Corporation's advances in bars, shapes, and plates have been a surprise, since they are larger than expected. In shipbuilding, 24,000 tons of material has been sold very recently for delivery in the last half of 1918 and the first quarter of 1919—truly decidedly forward buying. Ship plates are quoted at 7.50c. per lb. by Eastern plate-mills, with ordinary tank-plates at 6c. The Cunard Line has covered for between 40 and 50 ships to be built in the United States.

COPPER

While there is still talk of large purchases by the Allies for last half, none has been reported. In fact very little buying of any kind has taken place and the market is dull. A strike started late last week at the Laurel Hill refinery of the Nichols Copper Company on Long Island, which is a disturbing factor, no settlement having yet been reached. It is one of the largest producers of copper. Last Friday the Government bought 100 tons of electrolytic copper at 35c. for delivery in Washington on March 15. No Lake copper is apparently being offered since producers are sold up for months to come. As to exports, one authority states that despite blockades almost 1000 tons per month is being sent abroad. Considerable copper, however, has been sunk on lost vessels. An estimate puts the total that has gone to the bottom at more than 67,000,000 lb. since December 1, 1916. The entire market is a drifting one and difficult to gauge. Some business has been done, but it has not been much. The quotation for March delivery is unchanged at 36.25c., New York, at which some sales have been made. April metal has gone at 36c., while electrolytic copper for the last half has gone at 31c., New York. The April quotation stands at 35.50 to 36c., with May at about 35c. and June at 34c. The quotation for third quarter is about 31 to 31.50c. with 30.50c. asked for last quarter. The output of the Anaconda Copper Company for February is reported at 25,000,000 lb., against 22,500,000 lb. in February 1916. All the leading producers show a substantial increase for February, this year, over February a year ago. The quotation in London for spot electrolytic is £151, which is the same as a week ago. The exports to March 13, inclusive, were 12,506 gross tons.

ZINC

The dissatisfaction commented on last week still prevails. The whole market is dull when it should really be active. Stagnation in the spring season is abnormal. There have been no changes in prices since last week, March delivery being quoted yesterday at 10.62½ to 10.75c., St. Louis, with the New York price from 10.87½ to 11c. The April quotation is 10.25 to

10.37½c., with second quarter at 10 to 10.12½c., all St. Louis. Like the rest of the metals, the market is a waiting one. Zinc is plentiful, but the attitude of both buyers and sellers is to wait until it is definitely known what the foreign and domestic situations are to be. The spot market is little easier if anything, at 10 to 10.25c., but no large amounts are offered and buyers are not many. The present equipment of the Anaconda Copper Company's new zinc-mill is said to have a capacity of 60,000,000 to 65,000,000 lb. of electrolytic zinc per year, with a capacity later of 100,000,000 lb. per year. The London quotation for spot was £47 yesterday, unchanged from last week. Sheet zinc is unchanged at 21c. f.o.b. mill carload lots, 8% off for cash.

LEAD

Delayed shipments from the West have commenced to come in at this market in large quantities since Saturday. Previous to this more or less anxiety prevailed, so that spot metal was selling as high as 11 to 11.50c. The entire situation is so much easier that there is less anxiety all around and spot sold yesterday as low as 10c., New York. Sellers are in reality putting out feelers for business. The American Smelting & Refining Company's price is still 9c. for spot. In general the market last week was quiet. The explanation for the decided change is the fact that the railroad freight congestion has become very much better. It is not at all unlikely that in the near future the present premiums which the independents have been securing over the American Smelting & Refining Co.'s price may be completely wiped out. Lead for March delivery is quoted at 9.50 to 9.75c. with April metal at 9.25c. and May at about 9c. Re-sale lead was offered and sold at St. Louis at 9.75c. Late last week demand for April was larger than for March. The demand for spot lead has fallen off. London's quotation for spot lead is the same as a week ago at £30 10s. The exports thus far for the month have been only 13 tons.

TIN

Two developments the past week have had a marked influence on the market. One is the announcement by the American Smelting & Refining Company that it is now turning out, at its new electrolytic-tin plant at Perth Amboy, New Jersey, 600 tons per month from Bolivian ores and that after July 1, 1917, the output will reach 1500 tons per month or 18,000 tons per year. The other development is the threatened railroad strike. Both of these factors have tended to decidedly ease the market so that spot metal which was selling a week ago at 54c. sold yesterday at 53c. with more sellers than buyers. The strike possibility tends to cause holders of tin to turn it into money, since a strike would only tie up the tin. Some doubt is expressed as to whether the tin output of the new plant referred to will reach the proportion mentioned. This is based on the question as to whether sufficient Bolivian ores can be secured and whether the British interests will allow all this ore to fall into American hands. Anxiety as to the loss of tin from the submarine danger is abating quite perceptibly. It is pointed out that no tin-laden ship has yet gone down. In fact the whole tin market is regarded as having been remarkably fortunate since the war started. Late last week less than 100 tons was sold in a stagnant market. Early this week sales of about 100 tons were made at 47c., mostly Eastern shipment. About 100 tons went yesterday at 53c., due to the pressure on the market. The quantity of tin reported afloat is 3816 tons, with the arrivals so far this month at 1415 tons.

ALUMINUM

The market is entirely nominal and unchanged at 58 to 60c. per lb. for No. 1 virgin aluminum, 98 to 99% pure.

EDITORIAL

T. A. RICKARD, Editor

PATRIOTISM marks the action of a group of leading copper producers in selling to the Government 45,000,000 pounds of copper at 16.6739 cents per pound, delivery to be completed in four quarterly installments. We understand that the offer was voluntary, and it presages a general readjustment of prices, in anticipation of wise industrial regulation in the national interest.

AMONG the signs of the times it is pleasant to record the offers made by manufacturers to supply the Government either at no profit or at a minimum. From the chairman of the United States Steel Corporation down to the heads of small concerns the willingness is expressed to operate on the national account under Government supervision as to prices, the companies to receive not more than 10% over the vouchered cost.

LEADVILLE is to the front with a discovery of lead carbonate reminiscent of the early days, as will be seen by reference to the letter from our local correspondent. In the Silver King mine, on Yankee hill, a body of lead carbonate rich in silver chloride has been uncovered. During recent years most of the ore mined in the Leadville district has been sulphide, except for the zinc carbonate and silicate ores, so that the finding of another old-fashioned body of oxidized lead ore is more than interesting. Yankee hill is just east of Fryer hill, a locality once famous for rich mines, among which we may recall the Little Pittsburg, Robert E. Lee, Matchless, and Chrysolite.

TIN and tungsten deposits in the Black Hills of South Dakota are described in an interesting manner by Mr. John Bland in this issue. Incidentally he refers to a mill built by Fraser & Chalmers a quarter of a century ago that required little more than a thorough cleaning to be made ready for a new campaign. This is a tribute to the splendid workmanship of those master-builders at Chicago who played so unique a part in the development of American metal mines. They did their work well. Our compliments to the surviving member of the firm, Mr. W. J. Chalmers, whose youthfulness of spirit laughs at Anno Domini and links us with a pioneer epoch in Western mining.

DISCUSSION this week begins with a protest, made by Mr. Horace Stanton, against a railroad company's embargo on the carriage of mine-samples as baggage. We can understand the engineer's desire to take his samples with him and suggest that Mr. Stanton discuss the matter with the responsible official. Mr. Storms replies to the request, appearing in one of our recent

issues, for information concerning the effects of faulting on the distribution of rich ore. He gives several interesting examples that should prove instructive. Our friend Mr. F. H. Mason expresses doubt concerning a suggested method for socketing a wire-rope. We shall welcome a reply to his criticism.

STRUGGLE for mastery in the zinc world has become an interesting feature of recent metallurgic history. The Anaconda quite frankly assumes a position indicative of intention to play a leading part. Its activities are noticed in various quarters, where it is investigating other sources of supply. Butte & Superior is expanding into new fields, in spite of a potential production so great that it bears the reputation among informed metallurgists of being the greatest zinc orebody known today. It is estimated that by the end of this year the output of zinc from the mines at Butte will be at the rate of 30,000,000 pounds per month. This is nearly equal to the present copper production from that district. For many years the Butte & Superior regarded the zinc in its ores as a detriment and employed the skill of the ore-dresser to get rid of the obnoxious blende. Thousands of tons of jig tailing assaying 8% zinc were hauled from the mill-dump and used as ballast on the Great Northern railway. Though rather shallow the permanent way of that railroad is the longest zinc deposit in the world. Whatever may happen in the re-alignment of influences with the Anaconda, the Butte & Superior, the Elm Orlu, and the United States Steel entering the lists, it may be taken as certain that the ancient armed peace between the Matthiessen-Hegeler-Heckscher-Wetherill interests, parceling out a helpless American zinc vassalage between them, is destroyed, and a new map must presently be drawn.

READERS familiar with the number 835,120, signifying the basic patent of the Minerals Separation company, will be glad to read the story of the alleged discovery underlying that famous patent, even if the story comes from a domestic source, namely, the brief presented by the company's counsel in the Miami case during the recent appeal at Philadelphia. We do not regard this as a historical account, but it is interesting as the version put forward by the patentees themselves. The psychology of 835,120 is obscure, and is likely to remain so. Messrs. Sulman, Picard, and Ballot allege that they stumbled upon their discovery by ringing the changes on the proportions of oil used in the Cattermole sinking process, although a short time previous to the discovery they had bought Froment's patent and had been instructed by him how to use bubbles for floating

sulphide minerals. They say that they were led to froth-flotation by way of the sinking 'granule' of Cat-termole instead of receiving the necessary hint from the rising 'spherule' of Froment. All that can be said is that if they did so, they missed a logical inference and fell into an illogical success. However, it is well to place this story of the discovery on record where it will be read by those engaged in flotation, for the obscurity clinging to the birth of the Minerals Separation company's frothing method has been a factor in confusing the decisions of the courts—decisions that will be more numerous before the great litigation is ended.

CONSTITUTIONAL law has grown apace. The Supreme Court has recorded an addition to the confirmed powers of Congress. The country will feel relieved, for uncertainty as to how far legislation may go in matters vital to the welfare of the nation militates against peace, efficiency, and competency. The railroads have been stripped of more of their pretended rights, so that their position has become increasingly differentiated from that of private owners; in fact, they are public-utility servants, entrusted with the operation of what is neither more nor less than an arm of Government, and the recognition of this status has now been given renewed emphasis. On the other hand, the unions of railroad employees have also been further democratized by the decision on the Adamson law. They are shorn of the privilege to use the strike as a weapon of protest. Interference with the railroad service now becomes interference with the regulative machinery of the Federal government. Thus it appears that the public has gained security in the maintenance of traffic through the quarrel between the operatives and the operators of inter-State systems of transportation. Justice McReynolds, though dissenting from the majority opinion, has neatly summarized the points that must now be recognized as part of our organic law. He says: "it follows that Congress has power to fix a maximum as well as a minimum wage for train-men; to require compulsory arbitration of labor disputes which may seriously and directly jeopardize the movement of inter-State traffic; and to take measures effectively to protect the free flow of such commerce against any combination, whether of operatives, owners, or strangers." A pleasing circumstance in the closing of this hotly debated incident has been the prior agreement, between the parties directly in contest, to lay aside their differences and compromise upon a plan in conformity with the Act just sustained by the Supreme Court. That will promote a spirit of fellowship and tend to eliminate mutual suspicion and hard feeling, which makes for better service. Still more gratifying is the fact that the harmonious adjustment, reached in conference before the Supreme Court decision had been handed down, was the result of a frank recognition by the train-men and the managers of patriotic duty at a period of national crisis. The episode terminates in a triumph of democratic good sense that goes far to expiate the evil counsels through which the Adamson law was forced into being. In the end

it marks a step forward in good citizenship and good government. Although but three branches of the railroad service were originally involved it would appear that the Adamson law makes no discrimination. It undoubtedly applies, as its text declares, to "all employees who are now or may hereafter be employed by any common carrier or railroad." This would effectually dispose of the assumption, hastily made in some quarters, that privileged classes of labor had been set apart by the Act for exclusive enjoyment of its benefits. Contention over so plain a matter would be out of keeping not only with the language of the statute but with the commendable spirit displayed by the managers in meeting the views of the railway operatives.

The Search for Ore

In this issue we publish, with slight abbreviation, a paper on the exploration of metalliferous deposits written by Mr. W. H. Emmons, formerly of the U. S. Geological Survey and now Professor of Geology in the University of Minnesota. The subject is one of such immediate interest to the miner and one concerning which so little is written that we feel sure that our readers will be glad to have it placed before them. Mr. Emmons makes the useful observation that outcrops are generally depleted of their copper in base-leveled areas. Closer study should be given to many districts that have been passed as unpromising under the older standards of exploratory work. The recognition of the fact that an outcrop characterized by abundant sericite, kaolinized material, and chalcedonic quartz is quite as significant as the iron gossan, generally sought as an indicator of copper, is also important. The 'iron hat' is by no means a reliable guide. Sometimes the ore may be found underneath the hat, but as often the miner finds that weathering has left nothing worth while. Neither is the sericitized outcrop infallible, but a clearer understanding of its relation to copper deposits is much to be desired. It might have been well for Mr. Emmons to have called attention to the possibility of paragonite being developed along with kaolin and chalcedonic quartz under conditions similar, except for the presence of soda-feldspars in place of orthoclase or except for the circumstance that potash had not been introduced by the solutions responsible for the hydro-thermal changes. Considering that copper is so commonly an associate of sub-silicic rocks, in which potash minerals are largely wanting, it becomes worth while to investigate the relations of paragonite, this sodic analogue to sericite, for it might easily escape identification in the field.

We venture to take issue with Mr. Emmons in regard to tungsten. Only in a special environment may this metal be classed as one that dissolves slowly. Mr. Emmons might have thrown light upon the fact, now becoming widely observed, that tungsten is a common accompaniment of gold. The ore in many gold mines proves to contain tungsten, sometimes in quantity sufficient to admit of economic separation. The frequency

of this association arouses suspicion that the failure to note its presence may be due largely to inadvertence. Tungsten is found in a large number of the Californian gold mines; it is now known to be common in those of Colorado; it went long unrecognized at the Homestake, but today it constitutes part of the steady production from that great mine. Tungsten has also been identified in recent years as a persistent associate of copper ores, particularly in deposits formed at a high temperature, such as the great orebody of the Moctezuma Copper Company near Nacozari, Sonora. A study of the relations of tungsten to the other metals in these deposits would probably lead to new data concerning their origin. Wherever intense kaolinization has been in progress, a phenomenon so characteristic of a large proportion of the important orebodies of the world, alkaline solvents for tungsten are specially abundant. In the presence of potassium compounds wolframite is readily dissolved, forming a complex series of alkaline tungstates, all of which are highly soluble. In tungsten-bearing silicious dikes, which generally contain considerable orthoclase, subsequent faulting is common, as a result of which kaolinization has become pronounced, thereby leaching the tungsten, and frequently leaving limonite casts of the original wolframite crystals. Furthermore, nearly all wolframite contains minute quantities of disseminated pyrite, which hastens the destruction of the crystals when oxidizing. This forms insoluble basic iron sulphate, which is deposited as films and masses of copiapite, while the tungsten tri-oxide, although occasionally separating out as tungstite, largely reacts with the alkalis in percolating waters and is carried off in the drainage. Ultimately the leached tungsten may be fixed as a precipitate of insoluble calcium tungstate too finely divided to be recovered by concentration. Wolframite that has been enclosed in unfractured quartz, and thus protected from alkaline solutions, weathers out as a resistant mass in the outcrop. Aside from this it need not be regarded as a difficultly soluble constituent of ore. It is found in the residual accumulations close to the outcrops of tungsten-bearing quartz-dikes, and in the upper drainage leading from the deposits, but as wolframite is comminuted by attrition while the gravel is washed into the larger stream-beds it there undergoes decomposition and fails to remain in placers. Only deposits of scheelite, an insoluble lime tungstate, yield anything resembling placers workable for tungsten.

We would like Mr. Emmons to explain to our readers, and to us, what meaning he gives to the terms 'lode ore' and 'ore lodes.' Is he using 'lode' instead of 'vein,' to signify deposits filling fissures? We venture to make a more serious criticism, namely, the lack of reference to the writings of mining engineers as published in the technical press. For instance, it is unscholarly to ignore the articles recently contributed by Mr. Frank H. Probert on the 'Surficial Indications of Copper.' We might refer to others, but it is unnecessary. Mr. Emmons quotes writers in *Economic Geology*, the *Journal of Geology*, and the U. S. Geological Survey—in short, he

contents himself with reference to the work of official geologists either on the Survey or professors in the universities. We think he makes a mistake. While stratigraphy, paleontology, and the hypothetical phases of economic geology may be elucidated by the professional geologists, it is fairly certain that the work of exploration always has been and always will be largely in the hands of the kind of mining engineer who is willing and eager to make the most use of the aid that the science of geology offers to the art of mining. The habit of the gentlemen on the U. S. Geological Survey, even after they resign from the service of the Government, of complimenting each other by frequent mention is admirable so far as it goes, but it is ungenerous to ignore the work of the real pioneers of exploration. Ore is found by the miner and the mining engineer, not by the academic geologist, and it will conduce to a better understanding of the subject if our learned friends will enlarge their mental horizon.

Production of Gold

Sufficient statistical information is now available to warrant an estimate of the amount of gold produced in 1916. The output from many mining regions is not yet known, but, fortunately, 83% of the world's production of gold is made by the English-speaking countries, which issue estimates soon after the close of the year.

	1915	1916
Transvaal	\$187,343,185	\$191,501,929
Rhodesia	18,542,064	18,912,225
West Africa	8,276,394	7,834,234
Total, Africa	\$214,161,643	\$218,248,388
Western Australia.....	25,013,015	21,901,105
Victoria	6,801,835	5,252,143
Queensland	5,161,526	4,722,226
New South Wales.....	2,738,733	1,852,156
Tasmania	383,366	545,688
South Australia	177,472	124,020
New Zealand	8,739,792	8,186,850
Total, Australasia	\$ 49,015,739	\$ 42,584,188
Canada	18,977,901	19,162,025
India	11,477,316	11,152,904
Other British territories...	3,000,000	3,000,000
Total British Empire....	\$296,632,599	\$294,147,505
United States	101,035,700	92,316,400
Russia	28,500,000	31,000,000
Mexico	15,000,000	12,500,000
Japan and Korea.....	9,125,400	11,000,000
Other countries	27,000,000	26,000,000
Grand total	\$477,293,699	\$466,963,905

The pound sterling is taken at \$4.85. The African total does not include Madagascar, Abyssinia, Egypt, French

Guinea, and other minor contributors. Of the Australasian figures, South Australia includes the Northern Territory. The recent decrease in gold output from Tasmania is due mainly to the cessation of work at the Beaconsfield mine. In 1905 Tasmania produced gold to the value of \$1,470,000. All the Australian States show a decrease, but it is satisfactory to note that the diminution of output in the principal gold-mining region, Western Australia, is smaller than was at one time anticipated, but it is persistent. In 1903 Western Australia yielded \$42,679,437, and in that year Australasia contributed \$89,206,739 in gold. Last year the Transvaal made the highest production on record, comparing with \$61,259,286 in 1903, the year cited in the Australian comparison. Rhodesia and West Africa are holding their own. In 1903 they produced only \$4,174,513 and \$1,462,671 respectively. The Indian output of gold, all of which comes from four companies operating in the Kolar goldfield, is maintained fairly well, but it is known that the mines are beginning to show impoverishment in depth. In 1899 the Indian output was \$8,385,467, and since 1903 it has been maintained at a little over \$11,000,000 with a steadiness due to the regulation of production by the conservative managers of this group of mines. The Canadian output has increased during recent years, thanks to Ontario, more particularly the Porcupine district, where the Hollinger, Dome, and McIntyre mines are conspicuously productive. In 1916 Ontario produced \$10,117,549, or 52.8% of the Canadian total. The Yukon has lost much of its glory, the yield from this northern territory having declined to \$4,391,669 last year, as compared with \$22,500,000 in 1901. British Columbia yielded about \$4,520,868 last year, chiefly as a by-product from the large-scale copper-mining operations in the Rossland and Boundary districts. Throughout Canada, and particularly in British Columbia, the shortage of labor due to enlistment for the War has curtailed mining operations. The output of the United States declined to the extent of \$8,719,300 in 1916 as compared with 1915, but the estimate published at the beginning of the year may undergo a revision that will reduce the supposed loss. In 1915 the first estimate was \$98,891,100 or \$2,144,600 less than the revised total. Incidentally, this suggests the margin of accuracy in such statistical records. California is still the leading producer. Four States and the Territory of Alaska are responsible for 80% of the United States output. Of the gold produced in the United States only 24% comes from placers, and of this about one-half is won by dredging. Of the \$12,500,000 produced by dredging, about \$8,000,000 is contributed by California. The smelting of copper ores yields about 8% of all the gold produced in the United States and there is an evident trend toward an increased yield of gold as a by-product from large-scale copper mining. Japan's gold-mining industry has been much stimulated by the War; a gain of 20% in production is reported for 1916 as against 1915. New mines have been opened in the province of Idzu. The latest official figures from Russia were \$28,586,390

for the year 1915. The output of that country also has been stimulated by the War, and the State banks are reported to be paying a premium on gold in order to prevent export. This will help the statisticians, because stealing of gold in the mines causes much of it to pass into foreign hands, and so evade accounting. The chief gold-mining district is the Bodaibo, in the Lena watershed, which contributed 30% of the Russian output in 1915, when one company, the Lena Goldfields or Lenskoie, produced \$8,646,997 from 902,459 yards of gravel. Europe yields less than 2% of the world's gold output, for nearly all the Russian supply is of Siberian origin, the Ural being responsible for \$1,000,000 only. The gold mines of France, led by the La Belliere, had become less productive before the War, and those of Hungary are now chiefly of historic interest. The gold credited to Germany is largely derived from the smelting of foreign ores. The British dominions yield 63% of the world's gold. The British Empire, the United States, and Russia produce 90% of the world's output of gold.

The Decision

Never has a nation approached the supreme abatement of war more deliberately and more regretfully than the United States at this time. The American people believes in peace at any price, even at the price of war, and when it draws the sword it will be with the earnest expectation not only of shortening the existing horror in Europe but of preventing a recurrence of a like calamity in the future. The President has not identified himself with either extreme party, the militarists or the pacifists; on the contrary, he has represented the nation that recently re-elected him to leadership. The hesitation to become actively embroiled and forcibly to resent injury will give to the American decision a moral value that should prove effective. On the surface the belated participation in the conflict will seem prompted by an intention to assert the freedom of the seas, to protect commerce, and to protest against the abuse of diplomatic hospitality that accompanied a scheme to let loose the Mexican and the Japanese upon us, but history, making a closer analysis, will ascertain that the violation of Belgium, the deportation of her people, the butcheries in Armenia, and the assassinations on the Atlantic brought the American people to a realization of the fact that the world would be unfit for orderly living should such savagery emerge triumphant. It is no mere coincidence that in this moment of final crisis the republic founded by Washington and sanctified by Lincoln should respond to the call not only of the free peoples of France and England but of a new democracy that arises over the wreckage of the absolutism that has so long weighed upon the Russian people. This triumph of liberalism proves, if proof were needed, that the Allies are fighting for democratic principles, for the right to live and let live, for a place in the sun for all men. The great imponderables have weighted the scales of justice and right shall prevail.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Mine Samples as Baggage

The Editor:

Sir—Not long since I made a mine examination in Nevada, and during the investigation of the property, I took a large number of samples, all of which, after cutting down, were placed in the usual small sample-sacks, and these I put in two large canvas sacks of the mail-pouch sort, with a view to distributing the weight, as I had my outfit (working-clothes, etc.) also divided between the two sacks. When I reached the railroad, at Tonopah, and attempted to have the sacks checked as personal baggage, their weight caused the baggage-agent to inquire if the sacks contained samples. To preserve my reputation I reluctantly admitted that they did, whereupon he refused to check the sacks, informing me that they would have to go by freight, or by express. I was compelled therefore to open both sacks and to transfer all the samples to one sack, and my clothing to the other. He then checked the sack containing the clothes, and I was obliged to send the samples by express to San Francisco, or wait a week or more for their arrival by freight.

I was told, though not by the agent, that it was part of a general scheme to discourage high-grading. There was surely no need of it in this particular instance, and, if the excuse mentioned was the real reason for this custom of the railroad company, then, to make it effective, every lot of samples sent through the express office would be subject to search, which no engineer would contemplate with indifference. I seriously doubt whether this explanation is the true one, but rather, that it is wholly due to the desire to make more business for the express and railroad companies.

It seems to me that the railroad company, at least, makes a great mistake in adopting and continuing a business policy so narrow. I never managed a railroad, but I have run a mine or two, and if I were operating a railroad I think I would consider it good business to change without delay the policy above referred to. In Nevada the principal business is mining. It furnishes probably 90% of all the local railroad business in that State. Since this is so, it looks like a lack of business acumen to do anything that would have a tendency to place a handicap on the development of mining. An engineer goes out to examine a mine and returns with a lot of samples weighing anywhere from, say, 25 to 100 pounds or even more. These he must send home by express or pack them into the railroad car with him. It may be that as the direct result of this examination, the railroad company will eventually derive business worth

many thousands of dollars annually for a long time.

Possibly this phase of the subject has never been brought to the attention of railroad managers, for it seems, if it had, this parsimonious policy would be abandoned for a more liberal one that would encourage mining, not penalize it, and one that would ultimately be of direct and great advantage to the railroad company.

San Francisco, March 5.

Effects of Faults on Richness of Ore

The Editor:

Sir—That faults, both great and small, appear in many instances to have had a direct influence on the value of ore in that part of the vein adjacent to the fracture has long since been recognized. A vein in which the normal ore is poor, in many instances is found to have been enriched to a surprising extent just above the plane of the fault, while the ore below the break is usually of nominal value.

I have observed frequently that where the plane of the dislocating fault—or it may be a dike—is at a high angle, the enrichment may be found on both sides of the fracture. To no class of workers is the influence of these 'breaks' in veins more suggestive than to the experienced pocket-miner. Aside from the actual work of drilling, blasting, and timbering in his mine, careful and discriminating observation of geological conditions is the main business of the pocket-miner. He is a close student of these changing variations in the structure and character of his vein, and of the condition of the formation in which it occurs, or that may be intruded into it, as well as of the faults and seams that cross it, or that unite with it. He knows by experience that he usually finds his gold at the intersection of these various fissures with his vein, and he observes with painstaking care every change of condition, for on his understanding of these characteristics depends his success.

Generally, though not always, pockets of gold occur at the intersection of these planes, of which the vein is one. The two others are called 'crossings' and 'gold-seams.' The crossings are small fissures that strike across the vein at a high angle, regardless of the strike and dip of the vein itself. The 'gold-seams' comprise a second series of fissures, sometimes inconspicuous—often mere threads, which have a strike approximating that of the vein, but dip across it at any angle between horizontal and vertical. There are many exceptions to this—mines

in which a concentration of gold, a pocket, is found in the vein adjacent to a crossing seam, fault, or dike, with no third intersecting plane visible.

In a mine, near Groveland, California, I saw a vein, one foot thick, that was nearly flat and intersected a formation of vertical clay-slate. A fault, parallel with the slate in strike and dip, had dislocated the vein about 20 inches. The material filling the fault between the upper and lower segments of the displaced vein was filled with crushed slate and fragments of quartz, and was rich in coarse gold, producing several thousand dollars in about 70 ft. of drift. The vein itself, for 10 or 12 ft. on each side of the fault, contained ore rich enough to pay to work in an arrastra, but beyond that the quartz was without value. Another interesting occurrence was observed in the Bandarita mine, 10 miles east of Coulterville, in Mariposa county. There a vein, four feet wide, was prospected by a drift run from a cross-cut adit. The vein was low-grade—much too low to pay—but a felsite dike diagonally crossed the strike of the vein, and here on the hanging-wall side of the dike and along its intersection with the vein, was found an accumulation of gold, which was followed upward by the miners. This 'bunch' was worth \$20,000, so said the miners. It extended upward about 40 ft. along the line of intersection of the vein and dike. Why it did not go farther it is impossible to say. There was no similar accumulation of gold on the under side of the dike, in fact, scarcely any gold at all, though the quartz persisted.

Hundreds of pockets of gold, large and small, have been mined in California, and in nearly every instance the gold has been found at the intersection of two or more, but most commonly of three planes, as above described. One of the most profitable and consequently most noted pocket-mines in the State is the Bonanza in the town of Sonora, in Tuolumne county, four miles east of the Mother Lode. It is the most famous pocket-mine in California and has produced over \$2,000,000. It was discovered in 1850 and was worked for many years in a small way. Until the early 'eighties it had no mill, all the gold was recovered by use of hand-mortar and pan. In later years it was equipped with a small stamp-mill. The shaft is down over 1300 ft. In value the pockets have been worth from a few dollars to \$360,000. This latter was found 200 ft. below the outcrop, and the central mass was worth \$40,000, the remainder of the pocket being scattered for several feet through the accompanying quartz and dike-rock. The Bonanza 'vein,' if it be proper to call it such, is a dike of light greenish rock of felsitic texture. It is remarkably uniform in color and texture throughout, except at and near the surface, where it is much decomposed, soft, and stained brown by iron oxide. In the unoxidized portions the rock is usually filled with greenish chloritic scales. In width the dike varies from 8 to 16 ft.; it strikes north 30° east, and dips at 20 to 25° north-west. With the possible exception of a large diorite dike found at the 1300-ft. level, the Bonanza dike is the latest intrusion

in the vicinity. It cuts several other dikes intercalated in the slate and schist of the Calaveras formation. The slate, schist, and other rocks of this formation, strike N. 30° W. and dip 65 to 70° N-E. The most important of these rocks is a zone of clay-slate 4 to 12 ft. wide, containing 5 to 10% of pyrite in brilliant cubes. This is the metallic-slate of the miners—the pocket-making slate. West of this is massive argillite, showing slight slaty structure. On the east side of the pyritiferous slate is a zone of dense quartzose rock, probably silicified argillite, beyond which on the east is a bed of limestone. Still farther east other zones of slate, schist, quartzite, and limestone occur; these are cut by the Bonanza dike in the same manner as in the Bonanza mine, and in some of the slaty bands pockets of gold are found under much the same conditions. At this mine it is only in association with the band of pyritiferous slate that gold occurs—not in the slate, but within the dike. In the band of 'metallic slate' are four stringers or veinlets, not over three inches wide at any place, and usually but a small fraction of an inch. One of these fissures separates the massive argillite side from the 'metallic' slate; the other three are within the zone of this slate, and vary in their distribution, being from one to four feet apart. These veinlets are nearly parallel with the enclosing slate. The most westerly one is accompanied by thin strips of mineral that look like decomposed intrusive igneous material mixed with iron oxide and black oxide of manganese—the 'fuse' of the pocket-miner. Occasionally, in this same fissure, small strips of quartz, like a thin lens or ribbon, has formed. The remaining fissures contain only clay-like mineral, due to the crushing and decomposition of the slaty rock. These are the veinlets known as 'crossings.' A second series called 'gold-seams' cuts both the strike and dip of the slates and crosses the dike with a south-west dip. Presumably these crossings and gold-seams pass into the foot-wall slate, but as no mining has been done below the dike it is not known whether other pocket zones lie beneath. None are seen to outcrop at the surface in the foot-wall of the dike. Both crossings and gold-seams have had an influence on the dike, as the two systems of fracture were found crossing it, where they appeared as waving veinlets of quartz, which, together with three larger veins of quartz, divided the dike into a series of rhomboidal blocks.

The dike cuts the slate diagonally in dip and strike. A vein of quartz of variable thickness lies next to the hanging wall, being a replacement of dike-material. A similar vein lies on the foot-wall, and a third vein formed about mid-way of the walls, being separated from the hanging and foot-wall veins by two to six feet of dike material. These three veins are from an inch or two up to two feet thick, and, except in the vicinity of pockets, are practically barren of gold. In the lower workings of the mine these three veins united to form one vein, which occupied the middle portion of the dike, and with this change in condition the enrichment of the dike ceased, except here and there a small 'bunch' worth a few dollars. As mentioned previously, the 'crossings'

and 'gold-seams' traverse the dike in the form of veinlets of quartz—the crossings at a high angle, approximating the laminations of the slate, and the gold-seams, nearly flat, as they were in the slate. It was at the intersection of these crossings and gold-seams with the three veins of quartz in the dike that the pockets were found, and always opposite the zone of black 'metallic' slate—never elsewhere, in this mine. A remarkable thing is that years of experience in the operation of the Bonanza mine proved that, as a rule, the pockets of gold formed at alternate intersections; but the value of any pocket could never be anticipated. The gold was generally brilliant in appearance and often was accompanied by equally brilliant crystals of the tellurides of gold and silver, particularly petzite. The Bonanza dike is in the plane of a thrust-fault, the hanging-wall side having moved upward and to the west a distance of 16 ft., which is approximately the thickness of the dike. On the whole, the occurrence of the gold pockets in this remarkable mine might be described as an ore-shoot about 16 ft. long, from 12 to 16 ft. thick, and about 1200 ft. deep, on the dip of the vein, as nearly all of the gold recovered was found within those narrow limits.

W. H. STORMS.

Socketing a Wire-Rope

The Editor:

Sir—Notwithstanding the fact that the device for socketing a wire-rope that appeared in your issue of March 10 has the stamp of so well-known a firm of wire-rope makers as Roebling Sons & Co., I am disposed to doubt its security for three reasons. First, the strength of the joint is dependent entirely on the assumption that the surfaces of the individual wires of the rope become alloyed with the zinc to form a solid piece of metal. This may happen in the hands of a skilled operator. It is likely not to happen in the hands of the average mine-blacksmith or mill-wright, to whom such work is generally assigned. Even if the job is well done, I am inclined to think the breaking strength at the socket will be considerably less than that of the rope—an undesirable state of affairs. Second, I dislike the use of hydrochloric acid. Should a little of the acid be soaked up by the central hemp rope it would be liable to set up incipient corrosion from the inside outward, where it would not be detected easily, and might lead to a serious accident. It is a well-known fact that zinc chloride is barred as a soldering flux for electric wiring solely because of the danger that may accrue if the flux is not properly cleaned from the wires after the soldering has been done. Why not be as cautious in socketing a rope? Third, the heat of molten zinc may anneal, and, thereby, weaken the wire immediately below the socket.

An infinitely easier and, I believe, more secure way of socketing a wire-rope is to push the end of the rope through the socket, allowing a piece the length of the socket to project, wrap the rope below the socket, to

prevent unraveling, remove the central hemp rope, and bend the individual wires back into the socket, decreasing their length as the socket becomes filled, and, if necessary, cutting off those wires for which there is no room. Finally, hammer securely in place.

Incidentally, why is the purely nautical synonym for wrap, 'serve,' used in the description of Roebling Sons & Co. when the former is so much more readily understood?

F. H. MASON.

San Diego, Cal., March 13.

Some Pertinent Questions

The Editor:

Sir—In your issue of January 13 there appeared some 20 or more questions, which to date have been answered in one way or another. Our friend, Lucien Eaton, of Ishpeming, in your issue of February 10, described the various conditions that affect results in each case. He has not described all of the conditions by any means. As an example: "How far should a trammer push a loaded car on a fair track underground in one minute?" It makes little difference whether he is underground or out on the dump. It does make a difference, however, as to length of his legs, age of the trammer, his temperament, whether forenoon or afternoon, how long he has been on the job, whether 'bohunk' or an American lad getting a few dollars for his next year in college. Any and all of the questions could be answered in wide limits. To date there has appeared 70 inches of good reading devoted to this subject, and I am sure I voice the sentiment of the mining profession when I say that we want more such articles as 'The Nickle Plate Mine and Mill,' 'Trips Through British Columbia,' and 'Dredging for Gold on Seward Peninsula,' and numerous others of this kind that have appeared from time to time.

A CAREFUL READER.

Takilma, Oregon, February 17.

In local chlorination plants in California the cost of treating auriferous pyrite ranges from \$5 to \$9 per ton depending upon the cost and kind of fuel employed (whether wood or crude petroleum), cost of labor, and size and capacity of the furnace. Barrel chlorination is more satisfactory than the Plattner process, and for some ores is superior to cyanidation. The largest chlorination plants ever built and operated successfully in the United States were those at Deadwood, in the Black Hills of South Dakota. These plants have not been in use, however, for many years.

A SHIPMENT of \$25,000,000 gold was received at the Philadelphia mint on Saturday evening, March 10, from New York for account of J. P. Morgan & Co., it being necessary to keep the establishment open many hours after closing time. Added to what is already stored here, there is now approximately \$185,000,000 gold in the vaults. This quantity of gold weighs about 111 tons.

Exploration of Metalliferous Deposits

By W. H. Emmons

INTRODUCTION. *The exploration of deposits of the metals will never become an exact science. There will always be an element of uncertainty in prospecting and developing mines. In countries where the surface has been closely scrutinized, most of the deposits whose outcrops contain valuable metals have probably been discovered. Many metalliferous deposits, however, are normally so very much altered at the surface that the true significance of their outcrops is most likely to be obscured.

If a deposit is not exposed its presence may become known by some one of its characteristics that is different in kind or in degree from a similar feature of the associated rock. Thus, a deposit that is not exposed may be discovered because of its magnetic property. So few minerals are strongly magnetic that the value of magnetic surveys is limited, but the dip-needle has nevertheless proved of great aid in detecting magnetic belts, and these in some regions are associated with workable iron ores. The Cuyuna iron range of Minnesota, which does not exhibit any outcrop of iron ore, was discovered by drilling 'areas of attraction' that are due to belts of magnetic rocks associated with the iron ores. In some regions the use of the dip-needle is justified, even if it does no more than reveal the strike of the rocks, since a knowledge of the latter enables the driller to place and point his holes to advantage.

The measures of gravity by the use of the pendulum are so accurate, or the limit of error is so small, than one might detect the presence of a concealed tabular deposit approximately at the surface, 34 ft. thick, having a density double that of the surrounding rocks. However, not many deposits have a density twice that of ordinary rocks and a thickness as great as 34 ft.; if they lie a short distance below the surface the density or the thickness must be even greater. Consequently, there is not much hope of sufficiently developing the gravity method of detecting deposits of heavy ores to make it of practical value. If the limit of error could be reduced to about one-tenth the present factor, and if the rather tedious and painstaking methods of determining gravity that are now in use could be simplified, the method would promise some degree of usefulness in the exploration of certain types of heavy ores. This, however, seems unlikely, since great refinement of method is necessary to determine the degree of error that now exists. In the future, as in the past, the explorer will probably have to rely upon what he sees rather than upon some peculiar characteristic of concealed deposits.

Certain relations of the distribution of lode ores to geologic structures have long been recognized. They are deposited principally in regions of complex faulting and fracturing and in areas of volcanic activity. The earlier prospector found that it was profitable to scrutinize the mountainous regions, for these in general are most complexly faulted and fractured, and more likely to have been the centres of great igneous activities. In some regions, it is true, flat-lying rocks far removed from igneous centres yield deposits of the valuable metals; these, however, are rarely of the lode type.

Certain features of a region other than its outcrops may lead one to suspect the presence of ore lodes. Thus, the presence of placers will lead to a search for the sources of the metals they contain. In some regions, waters containing iron sulphate suggest the presence of deposits containing iron sulphides. At some places, many feet above the present streams, gravels are cemented by iron oxides that were evidently derived from the weathering of deposits containing iron sulphides. At Cananea, at Bingham, at Lead below the Homestake lode, and in many other regions, iron-cemented gravels are conspicuously developed. These gravels were consolidated, long before the mines above them were opened, doubtless by iron oxide that was deposited by hydrolysis of iron sulphate formed by oxidation of pyrite during the weathering of the pyritic deposits.

Lode ores, it is believed, are deposited principally by ascending hot waters. This inference is justified since they are almost universally associated with intrusive igneous rocks. The solutions that course through fractures and shattered zones soak into the country-rock. In some districts these solutions have wandered far from the master-fractures, profoundly altering great areas of country-rock. Where the prevailing hydro-thermal alterations are sericitic, as at Butte, and in many other regions, the rock is bleached. Where the alterations are propylitic, as in many of the precious-metal deposits of Nevada, igneous rocks, by development of chlorites from dark minerals, become pale green. Prospectors, even those without academic training, know the significance of hydro-thermal metamorphism. Some designate the result of such alteration as the 'kindly look' of the rock and contrast it with the 'hungry look' of the fresh unaltered rock which they have often found to be barren of ore.

Primary ore deposits fall into a few well-defined groups, each with characteristic features. These in different districts have definite relations to the geologic structure, depending on their genesis. The mapping of the structures and the investigation of the relations of

*A paper to be read before the St. Louis meeting of the American Institute of Mining Engineers in September 1917.

the deposits to structures are essential features of rational exploration.

Of the discoveries made in the United States within the past 10 years, perhaps as many have resulted from a knowledge of the geologic conditions of the districts containing the deposits as from the exploration of outcrops that were supposed to be the altered caps of valuable deposits. The exploration made with an adequate knowledge of the structure of an area and also with an understanding of its characteristic superficial alteration is the most likely to succeed.

Some outcrops themselves contain the valuable metals; others have had the valuable metals leached from them, but may carry the alteration-products of associated minerals, and these frequently furnish the clue leading to the discovery of orebodies. Pyritic copper-sulphide deposits and pyritic zinc-sulphide deposits are generally leached of copper and zinc near the surface. In the earlier days of mining many of the deposits were discovered incidental to mining associated metals less readily dissolved at the surface. In general, these deposits were stained with iron oxide. The copper deposits and zinc deposits of Butte were discovered by exploration of silver ores in the upper oxidized parts of the veins. The United Verde mine at Jerome, the Highland Boy mine at Bingham, and the Mount Morgan mine, in Queensland, were worked first as gold mines. All subsequently developed great bodies of copper ore carrying noteworthy amounts of gold.

Stimulated by examples of iron-stained rocks passing downward into workable copper ores, explorers investigated ferruginous outcrops systematically and many deposits were discovered below the valueless caps. Many of the disseminated copper deposits are barren of copper at the surface. The exploration of these deposits soon showed, also, that some are not everywhere capped by gossans heavily stained with iron oxide. The cap-rock in general is composed largely of sericite, kaolin, and chalcedonic silica. Some contain also sulphates. Such associations, though not so easily recognized as limonitic areas, are nevertheless significant and the recognition of the origin of such an outcrop is certain to play an increasingly important part in the explorations of the future. Because such an association of alteration-products is less readily recognized, outcrops of this character are the most likely to have been overlooked in an area that has not been fully explored.

The problems connected with the superficial alteration of ore deposits, although complex, are susceptible of analysis and experimental study. The changes are accomplished by water, air, and the compounds resulting from the action of water and air upon the ore itself. One may take the ore, expose it to water and air, and ascertain what products are formed. One may expose the ore further to the action of water and those products in the absence of air and ascertain the changes accomplished. By analysis one may ascertain the composition of the waters of mines. There are now available more than 50 analyses of waters from mines of sulphide ores.

These are similar in composition and closely resemble solutions formed by placing sulphide ore in contact with pure water. It may be assumed with confidence that the solutions that accomplished superficial alteration of sulphide ores are systems of sulphates, carbonates, and chlorides of heavy metals, of alkalies, and of alkaline earths. Near the surface the solutions are acid and generally contain ferric sulphate. In depth, ferric sulphate is reduced to ferrous sulphate, acidity is decreased by reaction with minerals of the ore and wall-rock, and at greater depths the solutions become neutral and ultimately alkaline. Subjecting for long periods various minerals and various combinations of minerals to solutions such as are known to accomplish superficial alteration, one may ascertain what changes take place and compare the re-activities of ores of the various metals and their re-activities in various mineral associations.¹

Some of the metals are easily dissolved near the surface where waters are acid and oxidizing. Of these some are precipitated in depth where acidity decreases and where solutions are reduced because oxygen of the air is excluded. Deposits of such metals are likely to be leached at the surface. If the metals are readily precipitated in depth the deposits become enriched below the surface. Other metals are difficultly soluble and because associated materials are dissolved and removed deposits of the former are likely to be enriched at the surface. Associated gangue-minerals are important also because some metals dissolve readily in certain associations but not in others. One may separate the metals into groups—one of metals that dissolve readily, another of metals that dissolve slowly, and still another of metals that dissolve very slowly.

1. Dissolve Readily	2. Dissolve Slowly	3. Dissolve Very Slowly
Copper	Mercury	Gold (in part)
Zinc	Lead	Bismuth
Silver	Antimony	Tin
Gold (in part)	Arsenic	Chromium
Uranium		Molybdenum
Vanadium		Tungsten
Iron		
Manganese		
Nickel		
Cobalt		

COPPER, because of its chemical relations, is easily leached from the surface and precipitated in depth. As already observed, the outcrops of a copper sulphide deposit may be so thoroughly leached that practically all the copper is removed and carried downward.

In base-leveled countries or in countries where the surface has remained nearly stationary for a long time, the outcrops are generally depleted of copper. Even in mountainous countries, where erosion is comparatively rapid, not many large deposits of copper are workable at the surface. Ferric sulphate hydrolyzes, depositing limonite, so the deposits of many iron-copper sulphide

¹W. H. Emmons: 'The Enrichment of Ore Deposits,' U. S. G. S. (1917), Bulletin 625.

ores are marked by a gossan or 'iron hat.' As already noted, many copper deposits have been discovered by following downward a nearly barren gossan or by the downward exploitation of deposits of precious metals that are concentrated near the surface above deposits of copper ores in which the precious metals are present in small amounts.

In copper deposits that do not carry sulphides the downward transportation of copper is generally slow. The native copper deposits of Keweenaw Point, Michigan, are workable at the surface, although the country has undergone erosion for a period so long that it has become nearly a peneplain.

Where the sulphides are present in subordinate quantities, copper carbonates and silicates may occur abundantly at and near the surface, as at Ajo, Arizona,² where oxidized copper minerals are conspicuous in outcrops.

In limestone, copper will commonly segregate as carbonate at and near the surface, and many oxidized copper deposits in limestone have been worked by open pits. Limestones that have been altered by contact metamorphism are relatively impermeable, because their tough, heavy silicates, such as garnet, amphibole, and mica, are not readily fractured. Most deposits of this nature contain considerable calcite, and any copper-iron sulphides they carry will usually oxidize to carbonates, silicates, and oxides. The copper in such an ore is particularly stable and is likely to endure long weathering. Such deposits have stimulated deep prospecting in many districts where other types of deeper copper ores are present,³ and they have thus served as useful indicators of hidden wealth.

The copper lodes in igneous rocks at Butte are leached of copper, some of them to a depth of 400 ft. The disseminated ores in porphyry show great variation as to depth of leaching, but are commonly leached to depths of 100 to 300 ft. below the surface, and exceptionally at greater depths. Some of them show practically no copper at the surface. At Cananea and Morenci, barren gossans that were explored to considerable depths have led to good deposits of chalcocite ore. Copper was only sparingly present at most places in the outcrops of the great disseminated deposits at Miami and Ray, Arizona. At Bingham it was locally somewhat conspicuous as carbonates and silicates.

In making explorations for copper the question frequently is raised whether drilling is justified in an area that shows but little iron oxide at the surface. Nearly all copper deposits mined in North America do show ferruginous outcrops, but some gossans that cap valuable disseminated ores in porphyry are not heavily stained with iron. At Cananea, Sonora, valuable chalcocite deposits occur below outcrops that show heavy iron stain

only here and there. As stated above, however, the outcrops show much silicification and kaolinization, and generally some limonite is present.

As a rule, the disseminated deposits of chalcocite ore will show outcrops more highly stained with iron in the earlier stages of their chalcocitization. As the country is eroded and the chalcocite zone descends, more and more pyrite and chalcopyrite are replaced by copper sulphides. A point may be reached where the chalcocite ore contains very little of the original iron sulphide. Obviously the oxidation of such an ore would yield but little iron sulphate. It would yield even less limonite, if the solutions were actively descending. If the process goes still further, the proportion of iron may become insufficient to dissolve all the copper in the chalcocite zone. The gossan then will generally carry oxidized copper minerals such as the carbonates, basic sulphates, and chrysocolla.

ZINC, like copper, is readily dissolved from its sulphide deposits and in the presence of much pyrite or other iron sulphide near the surface, the zinc is likely to be almost completely removed from its deposits. It forms the soluble zinc sulphate. But zinc in depth is not so readily precipitated by sulphides as copper. It will remain dissolved in solutions in which copper may be precipitated. Thus secondary concentrations of zinc-sulphide ores are rare compared with the secondary ores of copper.

In limestone, a solution of zinc sulphate precipitates zinc carbonate ores. These ores have lately become prominent, particularly in several districts of western America, where surficial changes have produced notable concentration of zinc.⁴

A common type of ore in limestone consists of pyrite, argentiferous galena, sphalerite, a little chalcopyrite, and other sulphides in a gangue of quartz. The orebodies, like many deposits in limestone, are commonly large irregular masses. In the oxidation of such a deposit the lead and much of the silver remain essentially in place, the galena being in part oxidized to anglesite and cerussite. The oxidation of pyrite and sphalerite yields acid, and zinc and iron sulphates, which are carried out of the deposits in great quantities. A part of the iron remains behind as oxide, but in some deposits practically all the zinc is removed. When the solution, which is doubtless acid and carries ferric, ferrous, and zinc sulphates, moving along a water-channel, encounters the limestone that surrounds the orebody, it will precipitate iron and zinc.

Under some conditions a zinc-iron carbonate or sideritic smithsonite, monheimite, is formed. This reaction has recently been investigated by Wells.⁵ Dilute solu-

tions of two metallic salts in equivalent (molar) quantities were precipitated with only enough sodium carbonate for one metal. With equivalent quantities of zinc and calcium nearly all the zinc and only a trace of calcium are precipitated. With equivalent quantities of iron and calcium, nearly all the iron and only a trace of calcium are precipitated. Sideritic smithsonite, or monheimite, contains iron carbonate in varying proportions. Some smithsonite is nearly pure and some contains as much as 20% of iron carbonate, or even more.

After it is formed the smithsonite, or monheimite, with the progress of the erosion of the country, is exposed to more highly oxygenated waters. The iron carbonate then oxidizes and stains the ore brown so that it may be easily mistaken for iron-stained limestone. Thus deposits of this character, though exposed in underground workings, have been overlooked for years.

SILVER, like copper, is readily dissolved in ground-waters. If the chloride forms in the gossan its solution is delayed. The chloride, however, is to be regarded as a temporary mineral except in arid countries⁶ where chlorine is commonly present in considerable quantities in earth waters. In such countries more chloride forms and, moreover, its solution is prevented by chlorides present in the waters. There may, therefore, be great enrichment of silver at and near the surface. In depth, silver is carried in acid solution. Air or ferric iron is necessary for its active solution in sulphate waters.⁷ However, the carbonate of silver is soluble and without much doubt some silver is carried downward in carbonated waters. Silver is precipitated from its sulphates⁸ and carbonates⁹ in a sulphide environment. For this reason great bodies of secondary silver ore may be deposited below a leached or low-grade capping.

GOLD is readily dissolved in acid waters that carry chlorides in the presence of manganese oxides;¹⁰ by reduction of acidity, gold is precipitated. Frequently the manganese and gold are precipitated together: in deposits that contain manganese, gold may be carried downward in solution and accumulate below the outcrop. But gold is readily precipitated from its solutions by many minerals, and its migration is slow. In the presence of carbonates¹¹ or of other minerals that yield alkalies readily, gold in manganiferous deposits tends to remain near the surface and in manganiferous carbonate gangue it may even accumulate as placers. If the metal were not of great value, its secondary concentra-

tion would be of little economic importance because it is dissolved near the surface only in chloride solution and chlorides are much less abundant than sulphates. In deposits which do not contain manganese, gold dissolves very slowly, if at all, and tends to accumulate at the surface, these deposits being enriched by removal of material other than gold.

URANIUM AND VANADIUM are readily dissolved in sulphate waters and both are regarded as mobile metals. Both metals are precipitated from the soluble salts by organic matter.¹² The carnotite deposits of Colorado¹³ are believed to be concentrations from cold ground-waters that dissolved the metals from associated rocks. In many deposits, vanadium minerals occur in relations that leave no doubt of their secondary origin.

IRON AND MANGANESE are grouped with the metals that are readily dissolved. In sulphide deposits containing iron and manganese these metals are generally present in ground-waters. The iron and manganese solutions, however, are not stable and the oxides of iron and manganese are readily precipitated by hydrolysis. Consequently deposits that contain appreciable amounts of iron and manganese will generally carry these metals at the surface. Secondary deposits of iron sulphide or manganese sulphide are almost unknown. In depth, iron and manganese are deposited along fractures as oxides and more rarely as carbonates, but these deposits in lode ores are of relatively small importance. Deposits of iron and manganese are commonly enriched by removal of other materials. In general, iron and manganese deposits carry rich ores at the surface.

NICKEL is similar to iron in its chemical activities, but unlike iron it does not oxidize from bivalent to trivalent salts and its sulphate does not hydrolyze and deposit oxide. It is dissolved almost as readily as copper in its sulphide combinations and it is precipitated in depth as sulphide. It is not so easily precipitated as copper sulphide, however, and will not be thrown down in an acid environment. It, therefore, resembles zinc in its migrational activities more closely than it resembles copper. No large deposits of secondary nickel have been recognized. The best known deposits of nickel sulphide ores have been glaciated and possibly secondary sulphide zones have been removed. At the Lancaster Gap nickel mine,¹⁴ Pennsylvania, secondary millerite is said to have been present in bodies of economic value. The gossan of nickeliferous pyrrhotite is essentially limonite. In the weathering of nickeliferous basic rocks the nickel accumulates as silicates not far below the surface.

COBALT salts are soluble and cobalt is dissolved readily from outcrops. No deposits of secondary sulphides are known. Its chemical behavior is closely similar to that of

nickel and zinc and it should be grouped with the metals that might be concentrated under favorable conditions. Like nickel, cobalt forms silicates and concentrates in the superficial zones of silicate deposits which are undergoing alteration. Cobalt, like nickel, forms a moderately insoluble arsenate in some outcrops. Cobalt is found in considerable quantities in the oxidized material which caps the altered peridotite at New Caledonia.

MERCURY is dissolved and re-precipitated in underground waters. The reactions proceed readily with chloride waters, but not in sulphate solutions. Mercuric chloride is soluble in water and does not give insoluble basic salts with water. Mercuric sulphate, on the other hand, is easily hydrolyzed and gives basic sulphate which is reduced to native metal. Experiments made over long periods by T. M. Broderick¹⁵ show that cinnabar is practically insoluble in sulphate waters, although it is readily dissolved in hydrochloric acid, and more readily still in presence of manganese oxide. The secondary enrichment of mercury deposits is somewhat similar to that of gold. Neither metal is appreciably dissolved except in presence of chloride. Re-concentration of mercury is most marked in arid countries where chlorides are present. Chlorine, however, is quite subordinate in underground waters compared with sulphates. The waters, therefore, could not move large masses of the metal and concentrate them as copper and silver are concentrated. Gold is so valuable that even small concentrations are important economically. Mercury is less valuable: a concentration of 2 oz. of gold per ton would be highly significant, but 2 oz. of mercury per ton would be unimportant. There is indisputable evidence that secondary mercury minerals result from processes of sulphide enrichment, but these are small in amount because chlorides in general are not abundant in waters of deposits of mercury ores. Mercury must be placed with metals that are non-migratory.

LEAD is one of the least soluble of the common metals, although the chloride is fairly soluble and the sulphide is dissolved in sulphuric acid in the presence of an oxidizing agent. The oxidation is attended by the formation of the relatively insoluble lead sulphate, anglesite. This coats the sulphide and tends to delay solution. Deposits with ores carrying galena will generally contain oxidized lead minerals near the surface. It is not uncommon to find galena partly altered to anglesite in the outcrops of deposits containing lead sulphide. Lead minerals, because of their low solubilities, are useful indicators of mineral deposits, and at many places have led to the discovery of silver, gold, and zinc deposits. Like deposits of other difficultly soluble metals, lead deposits are likely to be enriched by removal of valueless materials rather than by concentration in depth by the processes of solution and precipitation.

ANTIMONY dissolves slowly in the oxidized zone. Its sulphide deposits form the oxides which are about as

stable as the secondary lead minerals, cerussite and anglesite. In depth, however, antimony minerals dissolve readily in alkaline solution. The antimony salts unite with silver-bearing solutions and precipitate antimony sulpho-salts of silver. Antimony is not to be classed as a readily migratory metal though it plays an important part in the precipitation of the secondary silver minerals.

ARSENIC dissolves rather readily in acid solutions but if it is present as a salt of H_3AsO_3 much water will hydrolyze it, and if present as salts of a base-forming element these also are hydrolyzed. In an acid solution its salts are oxidized but do not migrate extensively. In alkaline solutions, however, they are easily dissolved and in depth the activities of arsenic in connection with the secondary enrichment of silver are important.

BISMUTH is more or less closely allied to antimony and arsenic. Like them it forms oxides near the surface in its deposits. There is no evidence of its extensive migration. From its chemical relations it is not likely that important secondary zones formed by the migration of bismuth will be found. Its sulphate hydrolyzes readily in water and in weak acid-forming oxides and its other salts also hydrolyze so readily that they would not be transported.

TIN is one of the more inert metals. The stannous salts, both sulphate and chloride, are easily soluble, but the stannic salts are readily hydrolyzed. Thus, in an oxidizing environment such as obtains in sulphide ores near the surface of the earth, the solution of tin is exceedingly difficult. The stannous salts when formed are oxidized to stannic salts and stannic salts will break down almost at once to the insoluble oxide, cassiterite.

Thus tin, although it may go in solution, will be almost immediately precipitated. Experiments by J. P. Goldsberry in the geological laboratory of the University of Minnesota have shown that cassiterite and stannite are both practically insoluble in tenth-normal sulphuric acid and hydrochloric acid. Doelter observes that tin oxide is slightly soluble in water. This statement was found by Goldsberry to be erroneous. The method of determination would have detected one part in a million. At the end of one month, a tenth-normal sulphuric acid, in contact with stannite and cassiterite, showed only faint traces of tin dissolved. Tin is enriched but little by migration in its deposits, because of the hydrolysis of its stannic salts which, as above stated, are precipitated as the insoluble oxide.

GOLD is not infrequently found in talc and serpentine. In these rocks it occurs in plates as thin as gold-leaf. It is extremely deceptive as to its quantity, rock supposedly rich in gold, judging by the amount in sight, sometimes assaying only a dollar or two per ton.

COPPER BARS to the value of \$10,801,118 were invoiced at the American consulate general at Valparaiso, Chile, for shipment to the United States in 1916, as against \$3,575,889 for 1915.

A CONTACT-FISSURE CONTAINING WOLFRAMITE ORE.

TIN AND TUNGSTEN MILL AT HILL CITY.

Tin and Tungsten in South Dakota

By John Bland

The little town of Hill City, South Dakota, is again enjoying the uncommon American experience of a tin boom. The first boom came in the middle 'eighties and bled two continents to the extent of seven and a half million dollars, the pocket-books of the poorer people of England on one hand, and on the other the more fortunate possessors of tin-bearing ground embraced within the 15 miles square around the base of Harney Peak, the summit of the Black Hills. Millions were expended for claims, but little for mining.

The second boom has been created by the Hill City Tungsten Production Co., which began operations in May 1916. It entered the field in consequence of the tungsten boom, but remains on account of the high price of tin. A history of a legitimate attempt to produce tin in America would be interesting, and the double feature of tin and tungsten recovered in the same mill gives the enterprise, with its bi-metallic basis, a strong bid for stability. Tin and tungsten in the same mill is not unusual. Cassiterite and wolframite are commonly associated in nature. Each has a specific gravity of 7.1, and

they are of nearly equal friability and hardness. A flow-sheet designed for tungsten of the Hill City variety is well adapted to saving the local tin, except that re-treatment to produce clean concentrate is not so necessary for tungsten as for tin, nor does the less value of the tin concentrate warrant treatment of the middling.

The tin ore is low-grade, and no important orebodies have been yet exposed. The mine from which ore for the past three months has been taken was completely developed by the old Harney Peak Tin Co. This development work, together with the mining machinery installed by the old company, has proved fortunate, because the orebody ranks as commercial only because the cost of the full development work, including equipment, does not have to be incurred in its extraction. It is a remarkable coincidence that the activities of the old Harney Peak Tin Co. should have exposed this, the best of the orebodies revealed in their expenditure of \$7,500,000. It is, moreover, only a little vein, which will not yield the cost of development work, plus that of extraction and concentration, even now with tin nearly three times as high in price, not to mention the higher recovery and the lower mill-cost at present obtaining. So it cannot be said that tin production has proved economical in the Hill City district, despite the fact that money is there being made in the exploitation of a tin orebody. However, it is true that excellent prospects exist, yielding a mica by-product that contributes to their profitability.

THE COWBOY OREBODY, which has supplied the Hill City mill for the past three months, consists of the following underground workings: A single-compartment working-shaft 300 ft. deep, and drifts averaging 70 ft. long from the 60, the 100, the 200, and the 300-ft. levels. The Hill City company has stoped out much of the orebody above the 60-ft. level. The ore is cassiterite in quartz; the crystallization is coarse, and occurs mainly in small seams of mica in the quartz. The whole orebody assays 1.6% metallic tin. It averages about 30 inches in width, and about 5000 tons is exposed. The company found the shaft recently re-timbered, the shaft-house, hoist, and boilers in good condition, and underground development work as stated above; so that the

only expense in preparation for mining consisted in the addition of a compressor and the building of a 60-ton bin. The ore is hauled one and a half miles down the old railroad-spur grade built by the Harney Peak company, to the loading-platform at Hill City, whence it is hauled in 50-ton cars on the C. B. & Q. railroad to the storage-bunker above the mill. The transportation cost of 75c. per ton includes the flat rate of 25c. by rail, plus 50c. per ton by wagon to the loading-platform. The concentrate averages about 53%, and is reduced to metallic tin in a reverberatory furnace of 1½ tons daily capacity. The recovery is about 85% of the metallic tin. The loss of 15%, together with the high operating cost, has induced the company to enter into a contract for the sale of the concentrate to the American Smelting & Refining Co., for treatment at Perth Amboy, New Jersey.

HILL CITY MILL. This plant is installed in the old mill-building constructed by Fraser & Chalmers for the Harney Peak Tin Co. in 1893, at a cost of \$250,000. The extraordinary strength of the materials used, the character of the great masonry foundations, and the site of the building, with its 11 floors, account at once for its great cost, and for its excellent state of preservation, as found by the Hill City company 23 years after its erection. No deterioration was found except in some damage to the roof and the broken window-panes. An 800-ton six-compartment storage-bin was built under the end of the railroad-spur, which was re-laid with steel for a quarter of a mile from the main line of the Hill City-Keystone branch of the C. B. & Q. railroad. Cars bringing ore from the Cowboy tin mine, and tungsten custom ore from the Lead-Deadwood district, dump into the bin. The ore is then trammed into the head bin above the crusher, thence passing through the mill as follows: 1½-in. grizzly, 11 by 14-in. jaw-crusher; trommel, 36 by 16-in. Chalmers & Williams rolls, trommel, 30 by 14-in. Allis-Chalmers rolls, Vezin sampler, sample to coffee-mill grinder, reject to 60-ft. elevator. The elevator delivers 96% through ½-in. ring, dry-product, to a 150-ton bin, which serves to make the crushing and concentrating departments independent of each other, the crushing machinery being designed to run one shift to supply the concentrators for three.

Ore is fed from the intermediate bin to three trommels in series; oversize from the first (running from 3 to 5-mesh) to Harz jigs; from the second (5 to 8-mesh) to Harz jigs; from the third (8 to 16-mesh) to Wilfley tables, undersize to cone-deslimer, oversize to 80-mesh duplex Callow screen, from which the undersize goes to a Deister-Overstrom table, while the slimer, 16 to 80-mesh oversize, passes to Bunker Hill screens, which split the feed into 16 to 24, 24 to 40, and 40 to 80-mesh sizes for Wilfley tables. The deslimed feed goes to the rag-plant.

The jig-middling is re-ground in 30 by 40-in. Allis-Chalmers rolls, the product from which is elevated to the first trommel, rejoining the ore-stream at its beginning. The middling treatment was designed for high-grade

custom ores from the Lead-Deadwood district, as follows: middling from jig to rolls, middling from all other tables to a storage-tank above the desliming cone. The middling from the 8-mesh down to slime is re-passed through the screens for re-sizing. The middling obtained in re-running the original middling is re-ground, the coarse sand going to a National disc-pulverizer and the finer sand to a 4-ft. ball-mill. This treatment was designed, also, for the 'dike' tungsten ores, which are described later. This flow-sheet shows close mechanical sizing, instead of water classification, and also a complex treatment of the middling.

Two months' pilot-mill experimentation in the old Black Hill tungsten-mill proved the advantage of close sizing and separate-middling treatment. Tungsten milling involves all but a new principle in gravity-concentration: that of producing clean concentrate. The extremely high penalty for insoluble in the concentrate warrants unusually expensive treatment to avoid it, and the close sizing of ore and middling was found to be indispensable in securing this result. Sliming must be avoided for the same reason. That accounts for the attempt to secure the greatest possible size of concentrate-particle, and for screening before each crushing in order to remove ore needing no reduction in that unit. The rag-plant, through which all the sand passes before reaching the tailing-dump, has been found indispensable here as it is in the Boulder district, Colorado. A one-cell flotation unit has been installed for experimentation on cassiterite, wolframite, and hübnerite.

Though the tin potentialities might some day seem to have justified so large a mill, and the tungsten custom-business even more surely, the reason for so large an equipment with so little indicated ore demands explanation. Although designed to treat 150 tons of tin ore daily, the construction cost less than most 30-ton mills. The building was practically a gift, including the pumps, jigs, elevators, trommels, engine, and many other things. The crushing and power machinery were brought from an abandoned gold-mill not far distant, and the Wilfley tables were bought at one-fifth of the standard price. No trouble has been experienced with the second-hand equipment. This buying was possible, in a year when new equipment was almost unobtainable, because no metal mines other than gold exist within 400 miles of Hill City, and abandoned gold-mills, many with good equipment in them, are as thick in the Black Hills as warts on the back of a toad.

Tungsten custom-ores constituted half of the basis of the operations at Hill City. The two other tungsten mills in the Black Hills, that of the Wasp Gold Mining Co. at Deadwood and the Homestake at Lead, are closed to custom business. Prior to July 1916, the Wasp had produced \$300,000 in tungsten concentrate from two Wilfley tables in its cyanide-annex, and the Homestake has been shipping a carload every four or five weeks for many months, dressed in a 20-ton mill. The Homestake deposit is, probably, the best tungsten orebody yet reported in the United States.

Excellent tungsten prospects are being developed in this district; they will soon be ready to ship to the Hill City mill, which is now being prepared to receive them. The Lead-Deadwood district, as proved in the cases of the Homestake and Wasp orebodies, bids fair to rival the Boulder and Atolia fields in richness, and unquestionably offers the best promise of large amounts of tungsten. The C. B. & Q. hauls ore direct from Lead-Deadwood districts to the Hill City mill, a distance of about 50 miles.

The Lead-Deadwood tungsten district has nothing in common, geologically, with the Hill City district. The orebodies are of different types: first, massive hübnerite associated with manganese in vertical shoots on quartzite contacts; second, as exemplified by the Homestake and

veins rich. On the contrary, the dikes are the more attractive for prospecting.

The orebodies fall into three clearly distinct types: first, pegmatite dikes; second, true quartz fissure-veins; and, third, a distinct type of quartz vein, lenticular, with both ends of the vein in sight, and the bottom always reached at about the same depth as the length of the lens. No seams or fissures are found connecting these peculiar isolated lenses; no continuity of strike or depth has been observed. These lenses are either barren or contain tungsten only. None have been observed carrying any other metal except in one case, where wolframite occurs at one end and cassiterite at the other; the two minerals are unmixed; in fact, each is in a different colored quartz. These lenses have no commercial value, as they are never

THE RAG-PLANT FOR TREATING DESLIMED PULP.

Wasp orebodies, fine-grained and extremely disseminated wolframite in a quartzite gangue, the orebodies being flat beds associated with the gold ore of the Homestake lode.

MINING DEVELOPMENTS. The single igneous intrusion that is important forms the Hill City district. Here Harney Peak caps the Black Hills, and ranks as the highest point east of the Rockies. The range is about 15 miles long, and from 2000 to 4000 ft. above the surrounding terrane. This granite mass and its associated pegmatite dikes is about 15 miles in diameter. The dikes fill fissures in the slate, rising from the same magma as the Harney range. Out of the dikes the quartz, mica, and rare minerals were forced into the adjacent slate, forming the quartz and mica veins of the region. Unfortunately, the main portion of the tin and tungsten remained in the dikes, concentrated, it is true, to ore along footwalls, quartz cross-veins, and faults, but not yielding concentrated vein-material such as is found in the Boulder district, Colorado. As great a total amount of tungsten doubtless exists in the Hill City district, but unlike Boulder county, the dikes are not barren and the

more than 100 ft. in length nor 2 ft. in width; nor do they carry more than 1.5% tungstic acid. A single exception is that of the Black Hills lens, which has recently been leased, with a 15-ton mill on the ground, to an operating company. This lens is of unusual size. A shaft 50 ft. deep shows a uniform widening from 16 in. at the surface, to 30 in. at the bottom, with a uniform content of about 1.8% tungstic acid. This type of ore is easy to concentrate, and, though small, the orebody is unquestionably profitable.

The second type of quartz vein is clearly distinct from the lens type. None of them carries tungsten, except one, which contains both tin and tungsten. This type of vein includes the Clara Belle, Holy Terror, and other gold mines, the Cowboy, Mohawk, Annie, and other tin mines. The Holy Terror yielded \$3,000,000 in gold to the 800-ft. level, and the Cowboy tin mine is now being worked to the 300-ft. level.

No appreciable amounts of tungsten exist in these 'true' veins, except in the Annie. The Hill City tungsten is not in the veins but in the dikes, which constitute a prominent feature of the landscape. Rising above the

Patent 835,120

Herewith we give the story of the operations leading to the application for this patent as recorded in the Minerals Separation brief in the Miami Appeal before the U. S. Circuit Court of Appeals at Philadelphia. For obvious reasons we have not edited the text in any way.

During the year 1902 and succeeding years, and until March, 1905, when the process of the first patent in suit was discovered and invented, Messrs. Sulman, Picard, and Ballot were at work studying and improving the Cattermole metal-sinking process. Their investigations covered a wide range, including painstaking but futile efforts to utilize air and gases in flotation, but failed to develop during this period any procedure capable of taking the place of the Cattermole metal-sinking process. Occasional flotation of metal or failure of metal to sink in the Cattermole upcasts, was troublesome, as it meant, of course, that the metal which did not sink went to waste with the gangue, but nevertheless metal flotation was investigated, and the ingenuity of the inventors was applied to it, and it was tested and to some extent patented, and finally dropped as practically useless, except as a tail-end annex to the Cattermole metal-sinking process for the recovery in the final tailing of that process, by film or skin flotation, of a small fraction of metallic matter which the Cattermole process was unable to recover. This appears in the report of May 18, 1904, of Sulman & Picard to the plaintiff reporting the joint work of Messrs. Sulman, Picard, and Ballot, under the heading 'Clean-up of dirty sands.' This was their final solution of the utilization of flotation ten months before the discovery of the process of the first patent in suit, and all their further efforts were concentrated upon the improvement of the Cattermole metal-sinking process.

In July, 1903, Sulman & Picard invented the process disclosed in their patent No. 793,808. This process, although never developed to any utility, was patented, and the defendant puts this patent forward as its justification of infringement. In this process an effort was made to recover the metal by flotation as a metallic film on the surface of water of particles brought to the surface by air or gas bubbles and left floating at the surface by the bursting of the bubbles on their emergence from the liquid. The process was useless because the amount of oil used, Cattermole or larger proportions, was so great that the attraction of the air-bubbles for metallic particles was in fact destroyed, and what was actually utilized was the coherence of the oil-coating on the metallic particles to an oil-film on the bubbles, when submerged. This coherence was weak, unreliable, and in fact useless, and disappeared when the bubble reached the surface. It was thought to be the attraction of heavily oiled metallic particles for air or gas bubbles,

and was therefore so described in patent No. 793,808. It was first tested by chemically generating gas in the pulp in the presence of heavily oiled metallic particles, and in this form was originated and tested by Sulman & Picard in July, 1903. In August, 1903, through the publication of the British patent to Froment No. 12,778 of 1902, they learned that this idea of floating oily flocks of metallic particles by bubbles of gas chemically generated had been anticipated by Froment. It was this circumstance which induced them to purchase the Froment patent and all improvements thereon for £225 sterling, or a little more than \$1000, negotiations for that purchase having been commenced in August 1903, and the purchase completed in November 1903, when they still had hopes of developing something out of this flotation process.

Another form of this film-flotation process was the use of a slowly revolving worm immersed in the pulp to force air-carrying atomized oil into the pulp. This is disclosed in the Sulman & Picard patent No. 793,808 as the second method therein. This worm apparatus was experimented with in the laboratory, but not in accordance with the disclosure of the patent, since Mr. Chapman always used Cattermole sand containing metal particles already oiled.

Another flotation process produced while the Cattermole metal-sinking process was being developed was that which is disclosed in the Cattermole, Sulman, and Picard patent No. 788,247, known as the 'soap and flotation' patent. This patent is merely for the application to all that was known of the flotation of metals in 1903, of an operation wherein soluble soap is mixed with water of an ore pulp, the soap is decomposed by sulphuric acid and oleic acid precipitated throughout the mixture to coat the metallic particles, and after the metallic particles have been concentrated they are treated with an alkali to clean off the oil and to again form soap, which can be again used in the process. The process is referred to in the report of November 19, 1903.

The two preceding reports of May 5, 1903, and September 24, 1903, are entitled 'Cattermole Process' and limited to the work thereon. The first reference in the reports to any effort to utilize flotation appears in the report of March 4, 1904. These tests were incidental to the completion of an experimental Cattermole metal-sinking plant which Mr. Chapman took with him to Australia in April, 1904, for the purpose of testing it there and erecting there a large commercial plant to carry on the Cattermole process. The experiments are described in the report under the heading 'Flotation Factor Used,' but it clearly appears that what was thus described as flotation was merely the upward movement of thickly coated oiled metallic particles in suspension in an up-current of water in an upcast as a tail-end treat-

ment for the recovery of a very small fraction of the metal in the tailing. Two tests are thus described, and in the last run, No. 4, chemical generation of gas was tried, but the "concentrates obtained 1.6%" of the metal originally in the ore were not encouraging. We therefore find that in the next report, dated April 19, 1904, four days after Mr. Chapman had sailed for Australia taking with him the experimental Cattermole plant, further work on a duplicate of that plant was supplemented by vanning experiments, and chemical generation of gas was tested therewith, and modifications of shaking tables were devised, and finally on May 18, 1904, we find the climax of all flotation work prior to the discovery of the process of the first patent in suit in the following statement under the heading 'Clean-up of dirty sands:'

"This work gives considerable promise of early success. As foreshadowed in our last, we have converted the small model vanning table into a 'bumping' table, and have removed the riffles. By this means on small samples of dirty sands we have been able to clean up nearly all the contained oiled mineral, and to produce sharp clean sands without the use of any gas-producing carbonates, etc., thus effecting considerable economy both in acid and carbonate. Under these conditions mere contact of the oiled particles with air when exposed on the surface of the table is sufficient to insure their flotation removal from the sand."

This marked the final perfection of flotation as developed prior to the wonderful discovery made in March 1905.

This skin flotation produced by exposing the metal particles to air and then permitting them to float by surface tension was actually used in the Cattermole plant erected in Australia and the Cattermole plant, with a capacity of treating 100 tons a day of 24 hours was completed and started in operation in April 1905. The oil consumption, however, alarmed the mine-owners, and the plant, after running for a few days, was changed over so as to spoil the Cattermole process and make all the recovery on the skin flotation tables. This occurred after the discovery of the process of the first patent in suit, but in ignorance thereof, as will later appear.

The discovery was made in the week between March 3 and March 10, 1905. The work of the laboratory for ten months had concerned only the Cattermole process. A Cattermole plant capable of treating 100 tons of material per day was in process of erection at Broken Hill, Australia, and the work in London was for the purpose of acquiring information which would be useful in carrying on the Cattermole process. It had been found that heat assisted this process. It had been found in the laboratory that a single-stage agitation reduced the oil consumption down to the lowest point that it ever reached in the Cattermole process, to wit: 1.5% of the ore and a very comprehensive investigation was being carried on of the influence of seven factors "on granulation." Six of these subjects of investigation were the essential factors which contributed to the discovery.

These factors are classified by Mr. Ballantyne, and are as follows:

- (1) Agitation and aeration such as was obtainable in the Gabbett or cone-mixer,
- (2) The use of oleic acid in place of the emulsions which characterized the earlier Cattermole work,
- (3) Heating of the pulp,
- (4) Fine crushing without desliming,
- (5) Reduction of the quantity of oil, to be continued regardless of results, and the experiments fully reported,
- (6) Acidification of the pulp.

When these factors were assembled and the quantity of oil was reduced step by step to the lowest limit, and the work was carefully, accurately, and thoroughly done, we now know that the discovery of the process in suit was inevitable.

Arthur Howard Higgins carried on these experiments under the direction of the inventors. He testifies as to having received instructions to carry out these experiments, and that these instructions were to start with "the upper limit of Cattermole's specified quantity, and reduce this as far as possible. In other words to find the lowest limit at which results could be obtained by the use of oil." Contrasting these investigations with his earlier work, he says as to this earlier work, that the quantity of oil "was always adjusted to give good granulation," and further:

"Q44. In adjusting the oil to give the best granulation, I presume you experimented with different quantities of oil?

A. Yes, there may have been different quantities, but whenever the granulation became imperfect by reason of the drop in the quantity of oil, the oil was naturally increased."

Three sets of documents written at the time record the discovery. They are the reports of Messrs. Sulman & Picard, the reports of Mr. Higgins, and the weekly letters of Mr. Ballot to Australia. First we have the Higgins report of March 2, 1905, and the Sulman & Picard report of March 3, 1905, describing the investigations up to this date and the scheme thereof with no mention except of granulation. Then the Higgins report of March 16, 1905, detailing the crucial experiments and announcing the result. The opening statement of this report is

"The effect of diminishing the percentage of oleic acid is to alter the type of oiling; the higher percentages producing granules, and the lower ones froth."

In the carefully tabulated description of experiments we find that with oil "0.32% on ore," the "float vastly increased," and that with oil "0.1% on ore," again the "float vastly increased." Experiments were tried with one-tenth of 1% of oil, and variations of the time of agitation, $4\frac{3}{4}$ minutes, 8 minutes, 12 minutes, and 10 minutes, and the last experiment with "0.5 cc. oleic acid" (one-tenth of 1%) and 10 minutes agitation, was selected for analysis, and the froth-concentrate was found to have recovered 87% of the metals.

The weekly letters of Mr. Ballot to Australia are only

copied in the record so far as pertinent. On March 3, 1905, Mr. Ballot wrote sending copies of the Sulman & Picard report of March 3, 1905, and the Higgins report of March 2, 1905. On March 10, 1905, six days before Mr. Higgins' report of the discovery, Mr. Ballot wrote as follows:

"I am pleased to tell you that during the week we have made some very important discoveries which will, I think, almost revolutionize our processes by way of simplifying and cheapening the same. I hope that by next mail the work will be sufficiently far advanced to send you full particulars. Several points have yet to be determined, and the discoveries are of such a nature that we have decided to take our expert and counsel's opinion thereon with a view to assuring ourselves that we can get good protection under patents. I may mention for your private information that we do not use more than 0.1 per cent of oleic acid per ton of ore and although we have not assays out that the recoveries will be very satisfactory."

This is the earliest document describing the invention, and fixes the date of invention as between March 3 and March 10, 1905. It shows Mr. Ballot's full knowledge and appreciation, and that patenting was even then under consideration.

One week later, on March 17, 1905, Mr. Ballot wrote, giving a remarkably full description and enclosing a copy of Mr. Higgins' report of the day before "received this morning." Every feature of the invention is accurately described. The only advantage of the invention that Mr. Ballot did not then know was that when the oil consumption "was reduced to a vanishing point, being only 0.1% per ton of ore treated," as he accurately says, it is not physically evident upon the concentrates and the concentrates may be subjected to subsequent physical treatment for separation into their constituent metals without washing off the mere trace of oil coating them. This was not necessary at Broken Hill, although the concentrates contained zinc, lead, and traces of silver. It was later demonstrated at the Saxbergets mine in Sweden, where the concentrates from the froth were subjected to magnetic separation and shaking-table treatment to separate iron, zinc, and lead. If, however, the concentrates are to be subjected to subsequent chemical treatment, as by cyanidation, the trace of oil must be washed off, as can be easily done with alkali, as suggested in Mr. Ballot's letter and in the patent.

The evidence as to instructions to Mr. Higgins, aside from his own frank statements above noted, is full and complete. William H. Ballantyne, the British patent agent who prepared the patent application was frequently consulted and was fully advised as to the Cattermole researches. He testifies as to the assembling of the factors, the drawing up of the series of tests, the declared intention to "reduce the proportions of oil to a vanishing point," and the disclosure to him on one of the days between the 8th and 15th of March, 1905, by Messrs. Sulman, Picard, and Ballot, of "their startling discovery of the agitation-froth process," and described

a demonstration made to him early in April, 1905, which, with his full knowledge of all that had been done before, he regarded as "little short of a miracle." He also describes the diligent following investigations resulting in the production of the continuous apparatus shown in the patent.

This brings us to the Sulman & Picard report of May 3, 1905, reporting the work done up to that time in working out "the new method of oil concentration in detail for forwarding to Australia." This report says:

"In determining the lowest limit of oleic acid which could be employed in granulating, it was found that granulation practically stopped at a range of about 0.5% of oleic acid on the mineral [ore] (60-mesh Broken Hill) in an acid circuit somewhat below 1% in strength. A certain amount of black mineral-froth was, however, noticed as a result. On successively decreasing the amount of oleic acid below 0.5%, it was found that whereas granulation ceased there was a growth in the amount of mineral float-froth under these conditions, and that the production of such float-froth appeared to reach a maximum when about 0.1% of oleic acid on mineral was used. This froth on collection was found to consist of oiled mineral slimes mechanically holding more or less coarse (oiled) mineral particles, the froth carrying between 70 to 80% of the total mineral present in the charge. The gangue-slime and the coarse sand are left quite white in the liquor below the froth, and the balance of the coarse mineral not caught up in the black froth, but remaining fixed with the sand, is found to have been efficiently oiled, and to be capable of complete recovery from the sand by table aeration."

With the slight correction noted in the bracket, this exactly sums up the newly discovered process as applied to Broken Hill ore with oleic acid as the oil.

Then follows a statement describing investigations which satisfied the inventors that the froth was due "to the air introduced by the Gabbett cone during agitation," that the production of froth was to some extent dependent upon "the amount of mineral slimes present and the fineness of the grinding," and that heat and acid were necessary in these operations.

The continuous plant was fully described, and was shown in a drawing made by Mr. Sulman and annexed to the report and all the methods of supplemental treatment referred to in the patent are described.

A copy of this report and its drawing were immediately sent to Australia, as appears from the memorandum on the report 'Copy sent to C. F. Courtney and Geo. A. Chapman 5/5/05—May 5, 1905,' and a similar memorandum on the drawing. Mr. Chapman testifies to receiving in June, 1905, instructions from Mr. Courtney, to whom all of Mr. Ballot's letters had been addressed, to change the Australian plant to take advantage of the discovery, and to receiving a drawing which he particularly identifies as a copy of the drawing attached to the report of May 3, 1905, and says:

"Owing to the trouble which had been met with in working our previous method, as a practical man, I was

very much gratified and relieved to know that we could substitute this more simple and ingenious process."

This marked the commencement of the commercial use of the invention, which will be hereafter referred to under that heading.

It may be noted generally as to the reports in evidence, prepared merely for the records of the company, the only remarkable fact is that they contain as much information as is contained in them. Very many subjects are only touched upon in the reports. For example, in the Higgins report of March 2, 1905, it is stated that during experiments directed by Mr. Sulman to determine the rate of change of granulation with temperature, the influence of other conditions was sufficiently marked to suggest their improvement, and that these conditions have been carefully examined but nothing identifiable by the reports alone further appears as to these other conditions. Mr. Higgins testifies as to these other conditions, which are evidently of no importance in this controversy, although one of them, as to the relation of the size of the revolving cone to the size of the vessel in which it revolves, is referred to at the end of Mr. Higgins' report of March 16, 1905.

Again, comparatively little appears as to the investigations of the Froment process and the process of patents No. 793,808 and 788,247, but this merely shows how relatively unimportant these useless flotation processes were. As Mr. Higgins says of his tests of the Froment apparatus in May or June, 1904:

"At that time a good many failures were only reported orally."

It is plainly apparent from the reports that up to the time of the discovery of the process of the first patent in suit, the one reliable process of ore concentration of Minerals Separation, Ltd., was the Cattermole process, and that after the discovery of the process of the first patent in suit the Cattermole process disappeared.

FLOTATION AT COBALT. The flotation plants at Cobalt generally use a mixture of pine-oil, coal-tar creosote, and coal-tar. A mixture of 15% pine-oil, 75 coal-tar creosote and 10 coal-tar is efficient. A 10% pine-oil and 90% high-sulphur fuel-oil mixture is used to float cyanide tailing with fairly good results. A chloridizing roast, followed by leaching either with cyanide or with an acid brine-solution has given the best results. The Buffalo mine is now treating 5 to 6 tons of flotation-concentrate per diem by a chloridizing roast, followed by an acid leach to extract the base metals, and then by a cyanide leach to recover the silver chloride. A 95 to 98% extraction of the silver has been obtained with this method.—Bull. Can. Min. Inst.

FLOTATION has been applied both to ferberite and to scheelite. The tungsten in the ore at Nederland, Colorado, is present chiefly as the iron tungstate, ferberite. Experiments with flotation on this material have not proved economically successful, owing to the fact that the associated valueless iron minerals also float readily.

Fixation of Nitrogen as Cyanide

*The earliest attempt to produce cyanide of soda by a reaction in which atmospheric nitrogen was directly fixed in the compound was by Lewis Thompson in 1839. His method consisted in heating for a period of half an hour, at a temperature of about 900° C., an intimate mixture of potassium carbonate (pearl ash) two parts, coke two parts, iron turnings one part. On leaching the cinder potassium cyanide was found to have been produced, which he converted into Prussian blue. A later attempt by Newton to produce cyanide directly by fixation of atmospheric nitrogen failed because of the necessity of operating at an elevated temperature, and also because he had not recognized the function of iron in the reaction. Prof. John E. Bucher of Brown University has recently investigated the subject further, using a ½-in. malleable iron pipe 30 in. long, enclosed in a larger horizontal pipe, so that the inner pipe might be surrounded with hydrogen or with nitrogen to prevent fusion of carbon di-oxide in the inner tube. He succeeded in fixing atmospheric nitrogen by first filling the inner tube with lamp-black and heating to a white heat in a current of hydrogen; sodium was then placed in one end of the tube and nitrogen passed through and allowed to bubble through water in a flask at the other end. The reaction is expressed by the equation $2\text{Na} + 2\text{C} + \text{N}_2 = 2\text{NaCN} + 46,200 \text{ calories}$. The fixation of the nitrogen was very slow, but the addition of finely divided iron resulted in a sharp increase in the rate of absorption. Following these experiments sodium carbonate was used instead of metallic sodium; a mixture of graphite, iron, and sodium carbonate was heated in the inner tube in a current of nitrogen to 920 to 940° C., when 60% of the sodium carbonate was converted into cyanide. This showed that Thompson's original claim that iron is necessary was correct and that subsequent failures with the process had been due to its omission. The function of the iron is catalytic. To render the process commercially practical Prof. Bucher has briquetted the mixture, which is dried until hard. The iron used was derived from iron-scale ground to 100-mesh in a ball-mill. The coke was next added, followed by the soda-ash. In the form of briquettes the charges put through yielded 28% of sodium cyanide when finished. Instead of using nitrogen, air was employed after passing it through hot coke, fixing the oxygen as carbon monoxide. The air thus prepared was successful. It was found that the reaction was most complete when only 20% of soda ash was present in the briquette. An increase beyond that point caused an actual reduction in the amount of cyanide formed. In practice the process is now conducted in vertical retorts, employing producer-gas for heating as well as for supplying the nitrogen. Ashless carbon is necessary as the ash from the coke accumulating with each repetition finally stops the process.

Nevada's Latest Gold District

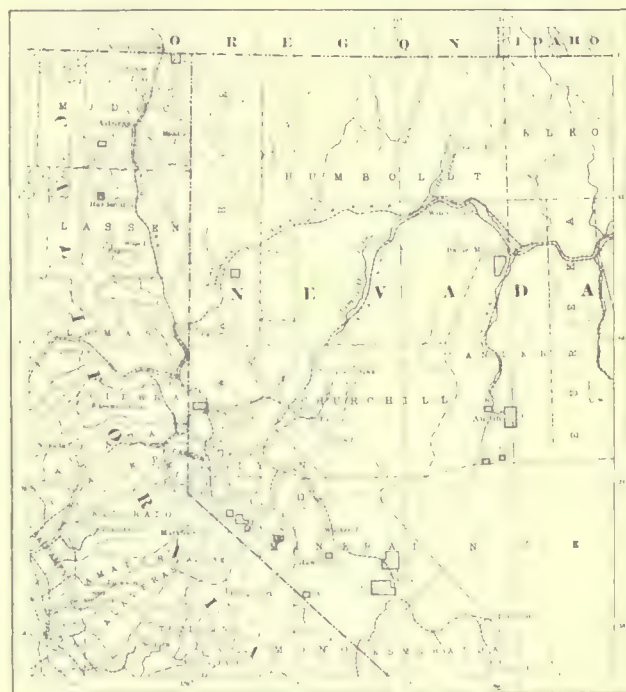

By Fred. J. Siebert

The camp of Olympia (which name must be changed on account of post-office objections) is situated 25 miles north-easterly from Mina, Nevada, in Mineral county, near the Nye county-line and at the extreme northerly end of the Cedar Range of mountains.

The principal claims, nine in number, were located in January 1915 by James P. Nelson, a prospector of many years' experience, and the most able, hard-working, and conscientious prospector I have ever known. Nelson named them the Royal George group. The ground had been located many times before but the rights had been allowed to lapse. In the higher hills there are many showings of quartz-veins in a later flow of rhyolite, which capped, to some extent, the older flows of rhyolite, andesite breccia, and biotite andesite. These veins strike east and west, and what little ore is contained in them seems too spotty to be profitable, so far as they have been developed. It was not until May 1915 that Nelson, after most careful prospecting, found on the Royal George No. 4 claim the obscure outcrop of a vein striking north-west and south-east in the older underlying rhyolite, near the base of the hills and dipping under them. By careful panning and sampling fresh signs of this vein were found for about 200 ft. along the strike. The actual outcrop was found in only two places about 65 ft. apart and assayed from \$15 to \$90 across an average width of about 7 ft., the assays running in the ratio of one ounce of gold to one and one-third ounces of silver. This vein was heavily capped to the south-east by Siebert Lake-beds,* which cover large stretches of the country below the elevation of the camp, 5975 ft. above sea-level. North-west the vein was covered by occasional patches of lake-bed, soil-wash, and laterite. After the strike was made known the usual trouble with claim-jumpers was gone through, and the absurd demands of our mining laws appeased through the usual 'cash' channel through the attorney's pocket. The ground was then purchased from Nelson by the Olympic Mines Company, a close corporation owned largely in San Francisco. Prior to this, development work was started by a partnership of four men who held a bond on the property. This development consisted of a shaft inclined with the vein at a dip of 43° to the 150-ft. level, where the vein turns off flatly, the shaft continuing on the same dip to a depth of 225 ft. and of levels at 100, 150, and 200 ft., besides cross-cuts, raises, and winzes, the total development amounting to date to about 2000 ft., most of which is in ore. In so far as the vein-bearing formations are concerned, practically all of the surface is totally obscured either by lake-beds, soil-wash, laterite, or flows of later

rhyolite and andesitic breccia. At one point on the strike of the vein and 930 ft. south-east of the shaft, remnants of outcrops are found imbedded in a hot-spring deposit that shows gold quite plentifully by panning.

Underground, four different rock-flows are found, all of which dip north-east at about 20°. The vein is a fissure crossing the oldest flow of rhyolite until the 150-ft. level is reached, where in places andesitic breccia forms the foot-wall. Usually, however, the vein is wholly within the rhyolite and for some distance only a few feet of rhyolite intervenes between the foot-wall and the underlying andesitic breccia. The workings disclose a

MAP OF A PART OF CALIFORNIA AND NEVADA.

strong, well-defined, normal fault striking north and south, and dipping east at an angle of 50°. This fault has had a remarkable effect upon the shape of the vein, as this sketch will show.

As the strike of the vein is N 40° W, and the strike of the fault N 7° W, the vein is synclinal in form, with the axis of the syncline coming to the surface toward the north-west, where it forms a junction with the fault and the vein. Toward the south-east, however, the syncline becomes deeper and the vein has much greater extent between the surface and the fault. One would naturally expect that from the point where the vein turns to an almost horizontal position, and up to the main line of faulting, there would be a great number of

*Named by Spurr, U. S. Geol. Sur., Prof. paper No. 42, 1905.

minor faults parallel with the main fault and also a broken condition of the vein, but no such condition exists. There was no hint of the fault until it was actually encountered, which seems to prove that the fault was very slow-moving, and the rocks in a plastic condition. From underground observation it would seem that this fault was contemporaneous with vein-formation. Evidently, however, the movement along the main line of faulting continued after vein-forming action had ceased.

Development work on the foot-wall side of this fault has not proceeded far enough yet to find the other end of the vein, but it has proceeded far enough to prove that the throw is over 60 ft. It is quite probable that a portion of the vein toward the north-west has been entirely eroded, but in a south-easterly direction the hills

RELATION OF VEIN TO FAULT.

rise to a considerable height and the south-westerly extension should be found there, if there ever was any extension. The vein originally was calcitic, but has been entirely replaced by quartz, leaving only the form of the calcite crystals. The vein-filling consists of solid white quartz and adularia with branching stringers into the soft wall-rocks as the limits of the vein are reached. The average width of the vein is about 7 ft., and the average value about \$23.50 in gold and silver. No evidence exists in the oxidized vein of any base metal other than a small amount of iron and manganese. The richest ore is chalky white, with no sign of mineralization. The gold is finely divided and evenly disseminated. It resembles the ore of the Gold Roads district in Arizona, while the enclosing rhyolite closely resembles the rhyolite at Jarbidge, Nevada. It is coarse-grained with large quartz phenocrysts, has a greenish color, and is well leached near the vein, particularly on the hanging-wall side.

Extensive tests prove that the ore is readily amenable to cyanide treatment after being ground to 200-mesh. An extraction of 98.2% was made by actual mill-test after 6 to 8 hours' treatment. A mill of 70 tons daily capacity is now being completed and is expected to be in operation early in April. Water has been piped 6 miles from an elevation 1500 ft. higher than the mill, which is placed near the collar of the shaft, a low trestle

connecting them. The mill is equipped with a 190-hp. Allis-Chalmers horizontal Diesel engine, which will be operated on 24° B. oil hauled from Mina, Nevada. Hendy crusher, ball and tube-mills; Dorr classifier, thickeners, and agitators; Oliver filter; and Merrill precipitation equipment constitute the plant. The assay-office and refinery are housed in the same building with a dust-tight partition between. This building is about 300 ft. from the mill and the pregnant solution is pumped up to it, the barren solution returning by gravity to the mill-supply tank.

The mill conforms in every way to ordinary up-to-date cyanide practice, the only extraordinary equipment being the Dorr classifier, which is 6 by 22 ft., and three Dorr thickeners, each 32 by 12 ft. Owing to the colloidal nature of the ore, a large settling-area with a dilution of about 10:1 seems advisable in the classifier, and for the same reason 30 sq. ft. settling-area per ton per day has been provided in the thickeners.

STRONTIUM is in more active demand at the present time than for many decades. The sudden increase in its use is due to the need of the brilliant red color in signaling with fires, rockets, and the like; furthermore, the oxide is employed in the extraction of saccharine matter from beet sugar, an additional recovery of 6 to 8% being obtained by this method over the results by the older processes. Germany and Russia each use about 100,000 tons per annum of strontium hydroxide in the sugar industry. It is adapted to a like use in refining cane sugar. The more desirable strontium mineral is the carbonate (strontianite), but the sulphate (celestite) is more abundant and can be sold in large quantities at about \$12 to \$14 per ton at the Atlantic seaboard. Celestite occurs to some extent in limestones and sandstones of Ordovician and Silurian age; occasionally also in similar rocks of later times. It is often found associated with deposits of gypsum, and is not uncommon as a gangue mineral in lead and zinc ores. Strontianite is likewise found in limestones, but more frequently in veins as an associate with barite, calcite, and pyrite. In many fluorite deposits it also appears, especially when barite is also one of the associated minerals.

LORENZO SUNDT, writing in *Economic Geology*, attributes the formation of sodium nitrate in the Chilean desert of Tarapacá, to the nitric acid present in minute quantities everywhere in the atmosphere. No electrical theory is required. The soda necessary for the reaction with the nitric acid is derived from the decomposition of the feldspar in the rocks. The reaction is rendered possible by the fogs which form along the front of the Andean range.

WHERE a machine can be run direct by a dynamo it should be done. It not only does away with the first cost and the subsequent wear and tear of a belt, but also it relieves the main shaft of a severe side strain and consequent friction.

Concentrates

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

NATIVE ANTIMONY is not uncommonly associated with stibnite. It occurs near Corona in Riverside county; near Bodfish, and on Antimony mountain, in Kern county; and in Wild Rose canyon, in Inyo county, California.

HEMATITE is iron sesqui-oxide. It is not proper to say 'hematite of iron.' Limonite is brown iron oxide, the chief difference between limonite and hematite being the presence of water of crystallization in the former. Roast limonite and it becomes hematite.

BISMUTH has a curious effect on gold, when alloyed with it. One part of bismuth in 2000 of gold destroys the cohesion of the atoms of gold to such an extent that the alloy can be crushed in the hand. Pure gold has a tensile strength of 14,000 lb. per square inch.

IRON in solution in water may be detected by the addition of a drop of potassium sulpho-cyanide giving a deep red color if ferric iron is present. Then add a drop of potassium ferro-cyanide. If ferrous iron is present a dark blue precipitate will form in the solution.

ANSWERING an inquiry from National, Nevada: a person who is not a citizen of the United States and who has not declared his intention to become one is not qualified to locate or hold a mining claim in the State of Nevada, nor in any other State where the United States land laws are in effect. Neither can an alien hold a mining claim that he has bought from a citizen locator.

AN EXPERIMENT made several years ago by the management of the De Beers mines in South Africa demonstrated that a cubic metre would contain about 1,167,000 carats of diamonds of various shapes and sizes, and that the lot would be worth about \$75,000,000. Diamonds have advanced about 100% in value since that time, so a cubic metre of diamonds may now be appraised at \$150,000,000.

THE FIRST tangential water-wheels made were those introduced in early days in California and were known as hurdy-gurdy wheels. They were rude in construction, without the scientific lines that characterize those of the present day, but the old hurdy-gurdy wheels, nevertheless, were the most efficient means of applying water-power that had been devised at the time they were introduced.

POTASH is in growing demand, and this has stimulated the search for materials that will yield this salt. Desert basins have been prospected in the hope that a large and easily available supply may be discovered, but thus far with scant success, with the possible exception of the Searles Lake deposit in California. Some varieties of

kelp have long been known to contain potash, and works have been erected at San Diego to treat this sea-weed in quantity to recover the potash. A discovery, made recently, that may be important, is that the stalks of bananas contain potash. The ash of a sample that was dried and burned contained over 10% potassium oxide, of which 74% was soluble.

TAILING from dumps of the East Rand Proprietary contained 1.71% sulphuric acid due to decomposition of mineral and salts during exposure to the atmosphere. This sand was to be used in filling old stopes, and as a large quantity of lime would be needed to neutralize the acidity, ash from boiler-plants was mixed with it, the whole being sent underground. The ash performs the function of a neutralizer and binder, and aids in the draining of the sand in the stopes. Transvaal coal, when burned, gives an ash containing 25 to 40 lb. of CaO per ton of ash.

AN EXPERIENCED MILL-MAN will feed quicksilver to the battery as it is required by the ore, and not in stated amount at a fixed time. The outside plates are always the best index as to when mercury should be added. The plates must be neither too hard nor too soft. Most mill-men aim to keep the upper end of the plate as nearly normal as possible, the central part a trifle soft and the lower end rather harder than normal. Extremes must be avoided if good results are expected. The plates must be watched, and kept in good condition by dressing as often as necessary, not at a stated hour each day.

THE MORTAR of a stamp-battery, that has been unprotected by liners and has worn through, may be effectually repaired by securing a piece of steel plate to the outside of the mortar by means of bolts passing through both mortar and plate. It is never too late to provide a mortar with liners. They may be made of forged steel three-eighths to one-half inch thick and cut to fit the ends and back. Put the back liner in first, the end pieces holding it in place, these latter being secured to the ends of the mortar by bolts which pass through and are kept tight by nuts on the outside. If possible cut the back plate so that it may be turned end for end when worn, the good half being then where the worn part had been.

VALUABLE MINES are not confined to any particular altitude, as the following will show: The altitude of Leadville, Colorado, is 10,200 ft. above the sea at Harrison Avenue; Cripple Creek is about 10,000 ft.; Ouray 7710 ft.; Deadwood, South Dakota, 4530 ft.; Lead at 5300 ft.; Butte, Montana, at the Court House, is 5767 ft.; Boise, Idaho, is at 2739 ft.; Prescott, Arizona, at the Court House, is 5346 ft.; Bisbee is 5300 ft.; Jackson, California, is 1975 ft.; Salt Lake City, Utah, is at 4248 ft.; and Park City at 6222 ft.; Virginia City, Nevada, is 6339 ft. The Alaska Treadwell mines are at sea-level, as are numerous others in Alaska and in British Columbia, while there are valuable mines in the South American Andes, at 15,000 to 18,000 ft. above the sea.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

LEADVILLE, COLORADO

RICH STRIKE ON YANKEE HILL.—THE BOHN SHAFT TO BE RE-OPENED.—OTHER NEW DEVELOPMENTS.

A discovery recently made at the Silver King mine, on Yankee hill, promises to be one of the most important developments that has taken place in the district during the year. A 3-ft. vein of lead carbonate showing a quantity of silver chloride has been found on the third level, at a depth of 140 ft. in what is believed to be the white lime that underlies the parting-quartzite. The same formation has just been cut at the Jamie Lee shaft of the Leadville Unit on Fryer hill, about a mile to the west, at a depth of over 600 ft., showing that, if it is true that the white lime has been reached at the Silver King, there must have been an enormous upheaval or roll in the formations somewhere between the two properties.

The part of the district surrounding the Silver King has never been developed and the work now under way there is the first piece of important exploration ever undertaken in that territory. The early-day mining men of the district neglected the area because they believed that all of the chief ore-bearing formations of the upper contact had been scored off by glaciers. Present-day authorities on the geology of the territory repudiate the old theory, stating that the blue lime has been found in place in several parts of the hill. This fact, together with the finding of ore in the Silver King, supposedly in the lower contact, makes the Yankee hill area loom up as one of the most promising parts of the district. Should continued development at the Silver King show the lead-carbonate vein to increase in extent and remain rich in silver there is no doubt that the coming summer will see much activity at a number of adjoining properties.

In addition to the discovery of lead carbonate and silver chloride, an immense body of low-grade zinc carbonate has been uncovered in the Silver King and the Brady tunnel, adjoining. Development in these deposits has been under way for several months and a number of shipments have been made. The ore is stated to contain around 20% zinc.

The Bohn shaft, one of the old producers of the Down Town section has been taken over by a local company of lessees who will re-open the property and carry on extensive developments. The Bohn has been idle for about 15 years and the shaft is in bad condition from top to bottom. It is 580 ft. A new electric hoisting-plant has been installed and the work of re-timbering is now under way. The first level in the Bohn is at a depth of 440 ft. Large bodies of iron and manganese were extracted from the property through the first level when the property was last active. Bodies of rich lead and silver ore are also reported to have been found in the mine at one time. The new operators, in addition to opening large deposits of manganese, expect to find extensive bodies of carbonate of zinc—an ore that was not recognized in the district until after the Bohn had been abandoned.

The old Anderson tunnel, now called the Ohio tunnel, near Birdseye, is to be re-opened by a new Ohio company organized by C. H. Weaver and H. A. Huttering, who, for the past year, have been interested in the property with the late W. B. Anderson. The entire stock has been transferred to the new company, which is financed to drive the adit an additional 2600 ft. into Prospect mountain. When operations were

abandoned last autumn, following the death of Mr. Anderson, the tunnel had reached a point 1571 ft. from the portal. It is equipped with electric-trolley and haulage-system and the property in general is in first-class condition for operation. It is reported that work will be resumed within the coming month.

The Fanny Rawlins property, on Breece hill, is about to enter another period of heavy production, one of the largest orebodies ever found in the mine having been discovered on the second level where development has been under way for some time. The shoot, which carries an average value of \$20 per ton, extends below the second level and has been exploited to some depth by a winze. A new drift on the third level will tap the ore, and as soon as this is completed, shipping on a large scale will be taken up. A small vein of 18% copper has also been cut in the new drift on the third level.

Patrick Mulrooney, owner of the Greenback property in Graham Park, is developing the mine after several months of pumping to drain the workings to the bottom level at a depth of 1350 ft. Station-pumps installed at the bottom and on the 900-ft. levels are handling the water. Large and rich bodies of sulphide ore are being exploited in the Greenback and a heavy output is being made. Shipping was started March 1, and up to the 20th, 600 tons of ore had been produced. The property is in shape for continuous operation and is expected to be one of the big mines of the district during the next few years.

The King Solomon Tunnel & Development Co., at Frisco, Colorado, is making elaborate preparations for resumption on a scale that will enable the property to become the heaviest producer in Summit county.

The Ontario, Tiger, and Green Mountain Leasing Co. rapidly is completing preparations to begin shipping from the shoot of high-level lead-gold ore recently encountered in the Ontario tunnel. New ore-bins have been built at the property and the road to the tunnel repaired for heavy hauling. It is reported that the first shipment will be made this week.

The ore-shoot is being developed above the tunnel level and continues as large as when first cut. Cross-cutting on the vein is also under way and other ore-shoots are daily expected.

There are approximately 115 properties in the district under development; of this number, 76 are producing and the others are either in the preliminary stage of activity or are undergoing extensive prospecting.

NEVADA

INCREASING SCALE OF OPERATIONS AT MASON VALLEY MINES.—EXTENSION OF PLANT PROPOSED.

The Bluestone mine commenced operations on November 20 last, shipping ore to the Mason Valley smelter at Thompson, by wagons to Mason, and thence over the Nevada Copper Belt railroad. At the same time the construction of three miles of standard-gauge railroad having a maximum gradient of 6% was commenced, together with the construction of one mile of electric haulage, joining up the main haulage-adit with the loading-terminal of the 3-mile standard-gauge spur from Mason. A compressor-plant of 2800 cu. ft. capacity was installed, motor-generator set, shops, office, and other buildings constructed. During the construction period of 3 months, 7000 tons of ore was shipped by wagon. Since March 1 ship-

ments have been going forward at the rate of 600 tons daily, and it is expected to increase this to 1000 tons daily by the last of April. Mining is carried on by the open-pit as well as shrinkage-systems, using Dreadnaught drills both mounted and as pluggers. Ore is dropped down through the main ore-passes to the 300-ft. or adit level, loaded into 5-ton side-tip cars of the Granby type, and hauled in trains of eight to the railroad loading-terminal. This terminal consists of a tunnel 180 ft. long into which two standard-gauge hopper-bottom steel gondolas are pulled by means of an electric-winch to two air-operated loading-chutes, the chutes being at the lower end of two raises 105 ft. long, which hold 300 tons each and into which the cars of the electric-haulage are dumped. The loaded ore cars gravitate out of the tunnel and onto the make-up track, and are hauled down the mountain to Mason by means of a Heisler geared locomotive.

It is expected that a concentration-plant will be erected during the summer to treat the lower grades of ores, of which there is a large tonnage. C. D. Kaeding is vice-president and general manager.

The smelter at Thompson is treating approximately 1000 tons daily from the Bluestone, Mason Valley, and Ludwig mines. As soon as the coke shipments are increased a second furnace will be blown in to take care of the increased tonnage from the Bluestone.

SUTTER CREEK, CALIFORNIA

PROGRESS AT THE BUNKER HILL.—AMADOR CONSOLIDATED MAKING HEADWAY.

E. Hampton, for many years Superintendent of the Bunker Hill mine near Amador City, has tendered his resignation to take effect on April 1, and at a meeting held March 15 by the directors in San Francisco, Chas. E. Bunker was appointed to succeed him. The bend in the lower part of the shaft has been straightened within the past two months and three crews of shaft-men are now replacing the decayed sets of timbers in other parts of the shaft with heavy new timbers. The 40-stamp mill is meanwhile crushing to full capacity; the rock from the lower levels in particular being above average value.

The shaft-crew at the old Eureka mine at Sutter Creek has reached the 1725-ft. level and, from now on, progress will be slower in clearing the shaft than heretofore, for the reason that instead of handling water only, it is necessary to remove the large quantity of sludge and rock that has accumulated in the bottom of the old mine during its long period of inactivity. The excess water caused by the recent storms is being handled by the pumps without difficulty and when the new hoisting-machinery is in operation and the larger skips can be put into use from the new head-frame, much better headway will be made in removing this debris. The installation of electrical machinery is almost completed. It is reported some very good ore has been found in the lower levels.

REPUBLIC, WASHINGTON

RENEWAL OF MINING ACTIVITY IN THE REPUBLIC CAMP

The demand for Republic silicious ore is increasing and leads to the impression that considerable activity will result in that camp the coming summer. The Trail smelter has had P. E. Racey here the last 10 days; he has sampled the Mountain Lion mine and is now sampling the Great Republic mine. For several months a deal has been on for the sale of the Republic mine, and experts believe in the probability of ore of at least good shipping grade being found below the deepest workings, now 731 ft. lower than the outcrop. The rich ore-shoot feathered out at a depth of about 625 ft. A winze follows the vein 125 ft. below the No. 4 adit-level, and drifts both north and south on the 700-ft. level follow the hanging wall, from which cross-cuts were driven by the Republic Consolidated Gold Mining Co., but no payable ore was found at that depth. R. G.

Edwards Leckie, who was then in charge, advocated the sinking of a vertical shaft to strike the hanging wall of the vein at a depth of about 1000 ft. I think D. C. Jackling favored Mr. Leckie's view, but the company was short of funds at that time. Transportation and treatment charges by the Granby company at Grand Forks, B. C., were then \$7.50 per ton, and the reduction of more than one-half of that expense is of itself a good reason for renewed activity in development in the mines of Republic.

During 18 days 350 tons of ore has been shipped from the Tom Thumb mine, which is again under lease and bond, with E. J. Delbridge as manager. The new leasing company has acquired also an option on the Rebate mine, which adjoins the Tom Thumb on the south. On the Rebate an adit formerly was run about 400 ft. and considerable driving on a 5-ft. vein developed a large quantity of very low-grade ore, much of which may now possibly become available for the smelters under the present low rates of transportation and treatment. The present plan is to extend the Rebate adit about 200 ft. north to the Tom Thumb vein. The leasing company is employing 16 men on two shifts.

A contract for sinking 500 ft. on the Last Chance mine, owned by the Lone Pine-Surprise Consolidated Mining Co., has been finished. At a depth of 485 ft. the vein was first exposed in one corner of the shaft and now extends entirely across it, but its full width has not yet been ascertained. Two men are employed sorting the ore. The shaft will be sunk to 30 ft. below the 500-ft. level, for a sump, when a station and ore-pocket will be cut. An aerial tramway will be constructed from the shaft-house to a spur of the Great Northern railway, in Eureka gulch before any ore is shipped to the smelters.

The sinking of the double-compartment shaft on the Lone Pine mine 150 ft. deeper has been started by the Northport Smelting & Refining Company.

During the first week in March the shipments from Republic to the smelters were as follows: Northport Smelting & Refining Co., 540 tons; Knob Hill Co., 530 tons; Moye Leasing Co., 40 tons; Tom Thumb, 150 tons.

The Knob Hill Co. reports that the lower adit on the Knob Hill mine will be extended to the Mud Lake vein, which, heretofore, has not yielded any payable ore. A fine looking vein on this property was formerly developed on the Republic early day plan of sinking shafts regardless of the whereabouts of a pay-shoot.

A rich streak of gray-copper is reported to have been recently discovered in the Lucille Dreyfus mine, near Danville, and an important strike of galena is reported from the Kettle River mine, at Rockcut, in Orient district.

SANTA FE, NEW MEXICO

MINERAL PRODUCTION FOR 1916 OVER \$34,400,000.

New Mexico's mineral production increased more than \$12,000,000 in 1916, according to the figures of the State tax commission, which are the only authentic figures available. Producers reporting to the commission show a total of \$34,410,488.68, and a few concerns failed to report within the specified time. In 1915 the gross production was \$22,489,000. The net value of the 1916 mineral output, as determined by the commission for purposes of taxation, was \$17,248,630, an increase of \$6,889,684 compared with the previous year, when taxes were paid on \$10,358,946. Under the New Mexico mine-tax law producers pay on the net value, at the rate fixed for taxable property in general.

The big increase in the production of the Chino Copper Co. in 1916 was principally responsible for the increase in the gross and net totals for the year. The Chino reported a gross output of \$19,219,767.18, as against \$11,383,777.48 in 1915, and its net, as determined by the commission, was \$12,600,293, as against \$6,846,204.

In addition to the Chino, other copper producers reported

large increases. The Burro Mountain Copper Co., the Phelps-Dodge concern that started production late in 1915, had an output last year of \$2,034,775.18, and took rank as the second copper producer of New Mexico, displacing the 85 Mining Co., notwithstanding the fact that the latter nearly doubled its production, reporting a total gross of \$1,456,587.29, compared with \$762,921.78 in 1915. The output of the Burro Mountain in 1915 was only \$72,059.29.

The Stag Canyon Fuel Co. led the coal producers in gross output in 1916, but failed to show a net production as great as that of the St. Louis, Rocky Mountain & Pacific, which ranked second. The gross of the Stag Canyon was \$2,903,568.25 and its net \$410,918, while the Rocky Mountain had a gross of only \$2,284,239.80, but a net of \$734,045.

KOREA

OUTPUT IN DECEMBER FOR THE ORIENTAL CONSOLIDATED.

The clean-up of the Oriental Consolidated Mining Co. for December is reported officially as follows:

Tabowie mill bullion	\$ 33,903.00
Taracol mill bullion	33,557.98
Maibong mill bullion	28,597.26
Taracol cyanide plant bullion	63,593.16
Maibong tube-mill bullion	4,588.41

Total\$164,239.81

The total tonnage milled for the month of December was

KUK SAN DONG DUMP-PLANT AND ORIENTAL CONSOLIDATED MILL.

27,123 tons. No returns were received from the smelter for account of the Taracol cyanide plant.

The mills operated steadily during the month with the exception of Tabowie, which crushed 10,448 tons only, on account of hanging up 20 stamps for 17 days while the four new mortars were being installed. This work was all completed on December 20. The mines operated steadily during the

month with the exception of Tabowie. On the morning of December 20 the cable of the centre compartment broke between No. 13 and 14. The cage went to the bottom with eleven Koreans who were killed. The next morning over 200 contract miners went on strike, demanding an increase in prices. They established pickets and prevented others from working. The management got between 20 and 40 men, including a few mill-hands underground, to push cars and kept the mill going. This partly accounts for the big clean-up at Tabowie, as they had to take the ore that was already broken, as the miners who were not in sympathy with the strikers were afraid to go to work. Thanks to the valuable assistance of the police the strike came to an end on the 27th and by the evening of the 28th the company had a full crew at work in their regular places at the same rates.

The large clean-up at the Taracol mill is on account of some high-grade ore from the Tongkol mine and a small bullion hang-over from the November clean-up. The Tongkol feeders averaged \$12.60 per ton for 745 tons milled.

The Taracol cyanide plant has an abnormally large clean-up, the actual extraction for December being 98.4%. This is caused by the \$60 per ton heads that were sent to the plant during the last ten days of November.

The hydro-electric plant closed down on December 21 for the winter. Taracol mine hoists are on steam and the company is buying ¥3000 per month of electricity from Okura & Co. to operate Taracol mine-pumps, No. 10 electric-hoist; Chintui mine, Nuchadagi valley shaft and pumping-station.

The Oriental Consolidated Mining Co. reports the clean-up for January at \$152,305. The grade of ore milled was above the average of that mined for some time past.

CANADA

MINERAL PRODUCTION OF THE DOMINION IN 1916.

The remarkable expansion of the mining and metallurgical industries owing to the stimulus given to production by the demands of the War, is shown by the preliminary report of the 'Mineral Production of Canada for 1916' issued by the Department of Mines. The total value of the year's output was \$177,357,454, as compared with \$137,109,171 in 1915, an increase of 29.3%. The total value of the metallic production was \$107,040,035, as compared with \$75,814,841 in 1915. Gold was produced to the amount of 926,963 fine ounces valued at \$19,162,025, as compared with 918,056 fine ounces of the value of \$18,977,901 in 1915. The increase in the output of the Porcupine mines more than counterbalanced a falling off in the production of the Yukon Territory and British Columbia. The production of silver was 25,669,172 fine ounces valued at \$16,854,635, as against 26,625,960 fine ounces valued at \$13,228,842 in 1915, a decrease of 3.6% in quantity but an increase of 27% in value. The production of copper has shown a large increase during the past three years. Last year's output amounted to 119,770,814 lb. valued at \$32,580,057, as against 100,785,150 lb. of the value of \$17,410,635 in 1915. The high price of the metal has stimulated production from the White Horse district of the Yukon, from which there were ore shipments of approximately 40,000 tons. Nickel was produced to the amount of 82,958,564 lb. of the value of \$29,035,497, the output of the Sudbury district being supplemented by a small tonnage from the Alexo mine in Temiskaming and nickel recovered as a by-product in smelting Cobalt ores. The production showed an increase of 21%. The output of lead was 41,593,680 lb. valued at \$3,540,870, a decrease of 10% in quantity but an increase of 32% in value. The zinc produced was estimated at 23,515,030 lb. of the value of \$3,010,864, a small proportion of which was recovered at the new electrolytic zinc refinery at Trail. The value of the cobalt recovered as a by-product from the silver ores of the Cobalt district is estimated at \$926,045. The demand for molybdenum has resulted in the development of several promising properties, which have pro-

duced molybdenite that is estimated to have a value of about \$159,000.

Shipments of iron ore were 339,600 tons, valued at \$814,044, as compared with 398,112 tons valued at \$774,427 in 1915. The Watana mines, Newfoundland, produced 1,012,060 tons, which was shipped by the two Canadian companies operating there to their Nova Scotia plants. Pig iron was manufactured to the amount of 1,169,257 tons valued at \$16,750,903, the production in 1915 being 913,775 tons of the value of \$11,374,199. In addition ferro-alloys to the extent of 28,628 tons, of the value of \$1,777,615 were made in electric furnaces. The production of steel ingots and castings established a new record, the total being 1,454,124 tons. The asbestos industry was particularly active with a total production of 118,246 tons, being a gain of 11%. The coal output showed an increase of 9% with a production of 14,461,678 tons valued at \$38,857,557. Each of the western coal-producing provinces shows a substantial increase, while the output of Nova Scotia and the Yukon has fallen off. The quantity of coke produced was 1,448,782 tons. The production of natural gas was 25,238,568 thousand cu. ft. valued at \$3,924,632, as compared with a production in 1915 of 20,124,162 thousand cu. ft. of the value of \$3,706,035. The falling off in the production of structural materials and clay products which characterized the two preceding years continued in 1916. The production of portland cement was 5,359,050 bbl. valued at \$6,529,861—a decrease in quantity of over 5%.

There promises to be considerable activity in the new gold district of Powell, Cairo, and adjoining townships when the snow leaves the ground this spring. About 300 claims have been staked since last fall, almost entirely on the original discovery. To facilitate recording of claims in the district, Cairo, Powell, Flavell, Willison, Alma, Holmes, and part of the Township of Baden have been placed in the Montreal River Mining Division instead of the Temiskaming division. This will allow stakers to record at Elk Lake.

JOHANNESBURG, TRANSVAAL

A RECORD PRODUCTION IN 1916.—THE GOLD OUTPUT OF THE RAND CAN ONLY BE SUSTAINED BY NEW DISCOVERIES

As generally anticipated would be the case, the Transvaal gold output last year constituted another record, which was mainly due to the better returns obtained from the Far East Rand new mines. The total production of gold was declared by the Chamber of Mines at \$9,295,538 oz. of fine gold of a value of £39,484,700, being an increase over the previous year of 207,867 oz., and in value of £857,509. The production for 1915 was a record for the Rand, but not for the Transvaal, and last year's output was a record not only for the Rand but also for the whole of the Transvaal. The previous record year for the Transvaal was in 1912, but last year exceeded 1912 by £773,389. Taking into account that the gold mines were deprived of some of their skilled labor by the War, these results were satisfactory, while the uniformity of the monthly output during the year was striking. Owing last year to a larger proportion of the tonnage milled coming from some of the best mines on the Far East Rand, the average production per ton milled was slightly better, and although the total tonnage milled during the year was again higher, the increase was not so striking as in previous years. It is evident that it will be only with difficulty that the mines on the Central and Western Rand will be able to maintain the output of last year at the same level, owing to several of the best mines becoming exhausted. The only hope for a maintained or slightly increased output lies in the Far East Rand, and it is doubtful whether, even here, the increased output during the next ten years will be able to make up for the declining output in other parts of the Rand. The Springs mine has just started the new mill, and at Daggafontein, Brakpan, New Modderfontein, and Government Areas, more stamps will probably soon

come into use, but otherwise there are no prospects of any substantial improvement taking place in the Far East Rand output during the next few years. It is therefore probable that unless the opening of additional mines on the Far East Rand is accelerated, the production of gold on the Rand will in the immediate future show a decrease rather than otherwise. Nevertheless the Transvaal is in a position to maintain the present output for several years, and naturally some years must elapse before the inevitable decline sets in, which, as before remarked, can only be delayed by the opening of additional mines on the Far East Rand. Up to the end of 1916 it may be said that since the year 1884, the Transvaal goldfield has produced 121,219,666 oz. of fine gold of the value of £514,908,454, while there probably remains an equal amount still to be worked, if the undeveloped areas in the Far East Rand are taken into consideration.

Although the Transvaal production of gold showed a striking advance last year over 1915, the total dividends declared showed a decrease of £553,212. The total amount paid in dividends last year amounted to £7,271,587, as compared with £7,824,799 in 1915. No less than 22 mines out of 51 paid diminished dividends last year, but the most striking feature was the failure again of the three great producers, the Randfontein Central, Crown Mines, and the East Rand Proprietary Mines to come up to expectations. These three companies alone declared £463,624 less in dividends than during the previous year. The Randfontein Central passed its dividend on account of the pending change of control, while the disappointing results at the Crown Mines were principally due to the experiment made during the year of narrowing the stopes, so as to reduce the quantity of low-grade rock being sent to the mills. The cause of the shortage at the East Rand Proprietary Mines, however, lies much deeper, and may be traced to the unsatisfactory value of the ore disclosed at depth, and the necessity of conserving the cash assets, in face of the heavy expenditure to be incurred in search of profitable areas. In 1910 this mine distributed nearly a million sterling in dividends to the stockholders, but last year the amount paid was only £61,148.

The majority of the mines which declared higher dividends last year, were the Brakpan Mines, Modder B., Modder Deep, and the Van Ryn Deep, situated in the Far East Rand. The City Deep situated on the Central Rand increased its dividend from £421,875 to £562,500, paying in fact a larger aggregate dividend, than any other mine on the Witwatersrand. With the exception of the Sub-Nigel mine, which increased its dividend from £10,790 to £43,158, all the gold mines in the outside districts of the Transvaal paid less dividends than during the previous year. The decline in the amount of dividends is claimed to be due to the higher cost of material and stores, to the expenditure of more of the working profits in capital expenditure and improvements, and to the declining earning power of several important mines on the Central and Eastern Rand.

PHILIPPINE ISLANDS

OPERATIONS OF THE BENGUET CON. MINES.

According to C. M. Eye, the superintendent of the Benguet Consolidated Mines, the report for the year 1916 is as follows: tons milled, 17,360; amount recovered per ton in gold and silver, \$16; total bullion produced, 173 bars, weight 21,076.8 oz. troy, containing 13,269.2 oz. troy fine gold, and 4316.8 oz. fine silver. Average fineness of bullion in gold, 630; in silver, 205. Total value of bullion shipped, \$277,854.73, or an average of \$23,154.56 per month. All values stated are in U. S. currency, and for bullion at mint. The actual mint returns have been taken in the calculations for the first nine months of the year, and for the remaining three months for which no mint returns have been received, our own weights and assays were taken.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

NENANA. The discovery of gold in the Toklat country in sufficient quantity to warrant the belief that there is a pay-streak there is of much importance to the people of Nenana, says the *Nenana News*, and it probably will lead to the rapid development of a district that is tributary to the town and which should be supplied largely, if not entirely, by local outfitters. The Toklat is a large district, with many creeks abundantly supplied with water and timber for mining purposes, and the fact that gold has been found on one of the streams should stimulate prospecting throughout the entire region. Nenana is the natural supply point for that, as well as other nearby, districts which require provisions and mining machinery.

ARIZONA

MOJAVE COUNTY

KINGMAN. F. R. Feitshans and W. E. Campbell have been looking over the McCracken property. A new company has been incorporated to take over the mines, which will be composed of F. A. Garbutt, president; C. A. Vehmeyer, vice-president and general manager; F. R. Feitshans, second vice-president; John R. Posers, secretary and treasurer; and W. E. Campbell. A large amount of steel and camp supplies was shipped to the mines. A camp will at once be established there and mining on a large scale will be begun. Feitshans and Campbell have also taken options on tungsten claims and made locations of ground covering more than 20 claims near the McCracken. The find is only five miles from Signal and close to the highway.

(Special Correspondence.)—A streak of specimen ore two to four inches wide has been struck in the Boundary Cone mine. The discovery was made on the 450-ft. level in a vein five feet wide. The rich ore makes along a slip and is being sought in a raise from the 500-ft. level, which has cut the slip. —The Big Jim mine reports assays from grab samples of \$54 and \$57 across 7 ft. in the east drift on the 600-ft. level. The east drift on the 400-ft. level is in solid ore which assays above \$20. This face is within 30 ft. of the east end-line, which separates the property from the Aztec of the Tom Reed; and but 70 ft. separates the workings of the two companies on this level.—All the material and machinery for the addition to the Tom Reed mill is in Oatman, or Kingman, the railroad shipping-point for Oatman. The foundations have been completed and redwood tanks are being constructed. Marcy ball-mills will supplant stamps, the present crushing-equipment. The new mill is expected to be completed by May 1. The capacity of the mill then will be 300 tons.—The Nellie shaft is 475 ft. deep. A station will be cut at 500 ft. and a cross-cut driven through the vein. The company's engineer believes that 500 ft. will carry the workings below the leached zone and into a zone of secondary enrichment.

Oatman, March 23.

PIMA COUNTY

AJO. The Ajo Cornelia Copper Co. is making preparations to prospect its property with diamond-drills. A contract has been let to the Longyear Drilling Co., the same company that drilled the Ajo Consolidated property. The Ajo Cornelia, according to J. D. Elliott, expects to drill 1000 ft. or more in the next 60 days, and to continue drilling until 10,000 ft. has been drilled and the size of the Ajo Cornelia orebody is determined.

The Ajo Cornelia property adjoins the Ajo Consolidated on

the south and east, which has blocked out with diamond-drills over 30,000,000 tons of ore. The Ajo Consolidated orebody can be traced into the Ajo Cornelia property. A two-compartment shaft is being sunk between two large fractures, showing a high-grade ore and is down to a depth of about 50 ft., but in order to prove quickly the value of the Ajo Cornelia property and the depth of the orebody, the directors, according to Mr. Elliott, have decided to diamond-drill and push the work with all possible speed.

YAVAPAI COUNTY

JEROME. The United Verde Extension Mining Co. has made an appropriation of \$2,500,000 for the erection and equipment of a smelter for operation in 1918. No new financing will be necessary. From its first year as an operating property United Verde Extension finished 1916 with a surplus of \$6,000,000, a large part of which was cash. Despite the fact that it was dependent upon custom smelters to handle its ores the company was able to produce its copper at an average cost of less than 6½c. per pound. The proposed smelter will have a nominal capacity of 1000 tons of ore per day. Its equipment will consist of two reverberatories and two blast-furnaces, but the management plans to have only one of each in operation at a time.

CALIFORNIA

The reports of oilfield work made to the State Mining Bureau for the week ending March 17, 1917, show 38 new wells started, making 249 new wells started since the first of the year, 15 to be inspected for test of water shut-off, 18 deepening or re-drilling, and 7 to be abandoned.

AMADOR COUNTY

(SPECIAL CORRESPONDENCE.)—The Plymouth Consolidated Mines (Ltd.) makes the following official report for the month of February:

Total tons milled	9,600
Value	\$56,200
Working expenses	27,927
Development	6,633
Surplus	21,640
Other capital.....	399

Plymouth, March 22.

PLACER COUNTY

It is reported that a portion of the Ayers' tract, across Bear river near Van Trent, eight miles north of Lincoln, containing an extensive deposit of copper ore, has been sold to a company of Eastern men. The purchasers are planning to begin work. There is considerable activity in copper mining in the foothills east of Lincoln.

SACRAMENTO COUNTY

NATOMA. At the meeting of the Natomas Consolidated Mining Co. on March 20, all of the old officers were re-elected. The annual report of the company states that there remains 250,000,000 cu. yd. of gravel that may be dredged with profit.

On March 1, 1916, Natomas dredge No. 1 was closed down to be rebuilt at another site, and was again started up on November 20, being closed down nearly nine months. On April 1, 1916, Natomas dredge No. 7 was sunk, and was not again operated until October 1, being closed down six months.

All of the company's dredges have been maintained in first-class condition for the most effective operation.

During the year 1916 the gross gold recovery from dredging

operations (25,868,000 cu. yd.) amounted to \$2,137,120, and the net operating profit was \$988,885. The sum of \$108,248 expended in salving and rebuilding Natomas dredge No. 7 was charged to operating expense.

The reclamation and drainage of the company's lands have been practically completed, and the larger portion of these lands was planted to crops during the past year.

The total cost to date of the reclamation work in district No. 1000 has been \$2,650,000, and in district No. 1001, \$1,620,000. Eighty-five per cent of the cost of the work in district No. 1000 and 43% of the cost of the work in district No. 1001 has been assessed against the lands owned by the company. The company has expended to date \$130,000 on the interior development of its lands in district No. 1000, in the construction of roads, warehouses, wells, and irrigation works. About 55,000 acres of the company's lands in these two districts is under lease, and it is anticipated that 50,000 acres will be planted to crops during 1917. The completion of the reclamation work enabled the company to obtain \$221,225 as rentals for its lands during the year 1916. The balance sheet as of December 1916 shows the value of gold and dredging properties to be \$8,373,439.

SAN BERNARDINO COUNTY

CIMA. The Copper World mine has purchased material for a smelter to be built at Valley Wells, 20 miles north-west of Cima. Valley Wells is south of Clark mountain and is the site of the old smelter, built 20 years ago, and later abandoned. The new smelter will have a capacity of 150 tons of ore per day, and will treat the ores from the Copper World, the Emperor mine, owned by Kunze and Conway, and other properties in the Clark Mountain district. The Copper World is now shipping 280 tons per month of high-grade copper ore and the Emperor about two cars per month. The smelter will enable these and other properties to handle their lower grades of ore, which will not stand the cost of shipment. The dump remaining from the operations of the old smelter will also furnish thousands of tons of material to keep the new plant in operation.

TRINITY COUNTY

CARRVILLE. The Railroad Commission has authorized the Trinity Gold Mining & Reduction Co. to sell to the California Oregon Power Co. for \$22,000 cash, its hydro-electric plant, including its transmission and distribution system, near Carrville, Trinity county. The electrical plant was built to furnish power to the Headlight mine, owned by the same interests which own and operate the power-plant.

The mine suspended in 1912, and shortly after the Trinity company contracted to supply 250 kilowatts of electricity to the Alta Bert Dredging Co., which runs a gold dredge near Trinity Center. Recently W. H. Estabrook bought the dredging company properties. The California-Oregon company has built a transmission line from Gastell, Trinity county, to Trinity Center, and wants to use the Trinity company's plant as an auxiliary power supply.

TUOLUMNE COUNTY

SONORA. Operations in the Hope mine, says the *Tuolumne Independent*, are confined to driving the tunnel to tap the old Tainter lead and the stoping of ore from a 3-foot vein exposed in an upraise in the tunnel 1000 ft. from the mouth. The ore extracted at this point is being put through the 5-stamp mill with profitable results. The tunnel is in 1350 ft., and it is estimated that another 200 ft. will intersect the famous old vein being sought. Nine men are employed in the mine.

Work on a three-compartment shaft on the Yosemite mine, situated near the Rawhide, has been started. The surface equipment is sufficient to sink the shaft down to a great depth. The orebodies will be tapped by cross-cutting.

The Springfield Tunnel & Development Co. has increased its capital stock to 1,000,000 shares. It is intended to raise money to continue the tunnel under Springfield flat.

COLORADO

BOULDER COUNTY

BOULDER. A 3-ft. vein of silver and lead ore has been struck on the lease operated by W. G. Paulding on the White Raven property, and it is estimated that the ore will run 100 oz. per ton. Paulding has been leasing for two years, and the ore he now has contains much wire silver.

The strike was made on the 100-ft. level. Paulding will take out a carload of the ore and if conditions warrant it, he will put a large force of men to work and develop the property.

LAKE COUNTY

The lessees on the Wolcott are shipping a steady tonnage of lead carbonate from an extensive shoot that is being developed in that property.

A company of local men recently organized by Harry McKeen has secured a lease on the Evelyn property situated on the east slope of Carbonate hill south from the Wolftone and south-west from the Greenback. The work of getting machinery in place and erecting a head-frame over the shaft is now under way. The Evelyn shaft is one of the best in the district and is comparatively new. It has three compartments and has a depth of 1200 ft. Aside from the shaft, little development has been done in the Evelyn property and no ore-bodies of importance have ever been uncovered by past operations. A small stope of high-grade silver ore was found in the mine at one time but the prospecting that followed its discovery failed to disclose other deposits. Bodies of iron are known to exist in the upper workings of the property and it is stated by those now in charge that extensive shoots of zinc carbonate will be found.

SAN JUAN COUNTY

SILVERTON. About six months ago George B. Croft secured a lease on the St. Lawrence and other mining properties, near Red Mountain, and since that time has been running a cross-cut tunnel toward a shaft, sunk some years ago, to reach the orebody at a lower level. According to plans and measurements, it should be necessary to drive 50 ft. farther to strike the ore vertically under the outcrop. Some high-grade ore was unexpectedly encountered and a sample brought down to the Beaumont at Ouray.

TELLER COUNTY

(Special Correspondence.)—The production of the mines of the Cripple Creek district for the month of February is reported by the mills and smelters as follows:

	Tons		
Golden Cycle mill, Colorado City...	32,000	\$17.00	\$544,000.00
Portland mill, Colorado Springs...	10,536	19.82	208,823.52
Smelters at Denver and Pueblo....	2,000	55.00	110,000.00
Portland Gold Min. Co., Victor mill.	18,750	2.27	42,562.50
Isabella Mines Co., Victor mill....	1,430	2.80	4,004.00
Worcester-Rubie mill, C. C. district.	250	3.90	975.00
	64,966	\$14.91	\$910,365.02

During February the Roosevelt tunnel was advanced 150 ft. For the last 50 ft. the heading has passed through hard mineralized phonolite. Low assays are reported from the dike. The consulting engineer for the tunnel company has been instructed to change the course of the tunnel to head for the shaft of the Portland Gold Mining Co. on Battle mountain.

Al. Osberg and associates of Cripple Creek have secured a three year lease on the Mable M. shaft and main workings of the Gold Dollar Con. Mining Co. on the eastern slope of Beacon hill.

Work on the new vertical (Frankenberg) shaft of the Modoc Consolidated Mines Co. is progressing rapidly. With the 500-ft. of the old shaft connected by raises, the new shaft is being timbered down to the ninth level. The raise from the 11th level of the old incline shaft is nearly completed. It is ex-

pected that the new shaft will have been completed down to the 1500-ft. level, and the new electric plant installed and in operation by July 1, 1917.

Messrs. Cornduff & Duncan, successful lessees on the Dead Pine property of the Granite Gold Mining Co. at Victor, have secured a two-year lease on mines of the Commonwealth Mining & Milling Co. This property is situated in Arequa gulch and on the north-east slope of Beacon hill.

The Copeland sampler has been thoroughly overhauled and is now occupied by the Eagle Ore Co. Additional equipment has been added by the Eagle Ore Co., so that they are prepared to handle promptly all shipments to the new sampler.

The annual meeting of the stockholders of the El Paso Con. Gold Mining Co. will be held at the office of the company in the Exchange National Bank building, in Colorado Springs, on Monday, April 9.

Victor, March 17.

MICHIGAN

HOUGHTON COUNTY

HOUGHTON. At a recent meeting of the Tamarack Mining Co. the shareholders voted to sell the assets of the company to Calumet & Hecla for \$3,600,000, or \$60 per share; 48,061 shares were voted in favor of the sale—more than the three-fifths required. There was no opposition. Thus, after many years of negotiation, the Tamarack mine has at last passed to the ownership of the Calumet & Hecla company. This company had paid, up to July 1, 1916, a total of \$132,250,000 in dividends, equivalent to \$1322.50 per share.

Production at the Mass Consolidated mine will be pushed as fast as men can be secured. About 450 men are now employed and 100 more could be used. The stamp-mill is handling production easily and not working to capacity. Three boilers at 'C' shaft are being replaced by three larger ones that will add one-third to the capacity. The old boilers will be moved to the mill at Keweenaw bay, where they will be used as a reserve unit. It is planned to sink 'C' shaft about 400 ft. and carry on development below the 1300-ft. level as rapidly as men can be spared for the work. These operations are expected to add 1,000,000 tons of rock to the present reserve, estimated to be enough for three to five years.

MONTANA

SILVERBOW COUNTY

Manager John Gillie of the Anaconda Copper Mining Co. says that the fire situation at the Leonard, West Colusa, and Tramway mines is considerably improved. Work has been resumed with nearly normal crews at the West Colusa and Leonard and progress in fighting the flames and gas at the Tramway is being made. Owing to the fact that considerable water was thrown into the Tramway, which caused the bulkheads to settle and crack, permitting gas to escape from the imprisoned areas, headway is slow, but it is believed that the situation has been brought under control. Several days will be required to complete the work of bulkheading, but confidence is expressed that the fire and gas eventually will be confined in so small an area that work can be resumed under practically normal conditions.

NEVADA

The output of metals for Nevada during 1916, according to the United States Geological Survey was as follows:

Gold	\$ 9,000,000—	22% decrease from 1915
Silver	9,000,000—	23% increase over 1915
Copper	28,120,000—	134% increase over 1915
Lead	1,596,000—	104% increase over 1915
Zinc	4,759,000—	57% increase over 1915

Despite a decrease in gold output of over \$2,000,000 from 1915, Nevada continues to hold the fourth place as a gold producer, as in 1915. California, Colorado, and Alaska each having a larger output.

There was a decrease of nearly a million ounces of silver, but owing to the higher price of silver there was an increase in value of output amounting to nearly two million dollars. In silver production, Montana was first, Utah second, and Nevada third. While the production of the Tonopah district decreased, that of the Rochester district increased in both gold and silver. In the Comstock district there was an increase of approximately 60% in the value of the gold and silver output.

(Special Correspondence.)—The Legislature has enacted a measure providing that the Industrial Insurance Commission may take charge of any case in which it is shown that companies are not giving employees proper medical and hospital care, charging all expenses to the employer. The bill was fought by the mining companies on the ground that it admitted many abuses and reflected on employers.

A bill has been passed creating a State Bureau of Mines, and is certain of the approval of Governor Boyle. It will be operated along the lines of the Californian institution, plans already being made for much field work.

By a close vote the Senate defeated a bill to tax the gross output of mines. Opponents of the bill stated it would prove a prohibitive measure for the mining industry if adopted, and that the mines were already bearing a heavy burden.

The Legislature authorized the establishment of two new schools of mines, one at Goldfield, the other at Ely. Each community is expected to contribute to the support of the institutions, which will be modeled along the lines of the schools at Tonopah and Reno.

Nevadan mining will benefit largely from the new Highway measure, which provides for several excellent roads. The main highways will extend from a point east of Elko to the Californian line, by way of Reno, and from Elko to connect with the roads to Los Angeles, passing through Ely, Tonopah, and Goldfield. There will be several connecting roads.

Carson City, March 19.

NYE COUNTY

(Special Correspondence.)—Plans for the extensive development of the old Tybo mine to the 800-ft. level are being carried out by the Louisiana Consolidated Mining Co., which has recently acquired that property, 110 miles north-east of Tonopah. The mine is credited with an output of \$5,000,000 from 1872 to 1880 and was worked down to the 400-ft. level. A good force is employed and the property is being equipped with a Diesel-engine power-plant, with electric generators, compressor, new hoist, and two sets of electric pumps. Later on power will be secured by the 30-mile extension of the Nevada-California Power Co.'s transmission-line from Belmont, after which the plant will be held in reserve as an auxiliary. A number of prominent Eastern capitalists have become interested with Walter E. Trent in the Louisiana company and they have decided to build a 500-ton smelter at Tybo, as well as a railroad that will connect either with Ely or Eureka on the north and Tonopah on the south. The bill granting the franchise for this railroad was passed by the Legislature and signed by Governor Boyle on March 20.

Tybo, March 22.

STOREY COUNTY

(Special Correspondence.)—The Overland, Democrat, Lager Beer, Succor, and School mines at Silver City have been acquired and merged by a New York syndicate represented by Oscar Daube. It is stated work will start at once with Walter Techow, superintendent of the Andes mine at Virginia City, in charge.

Preparations are being made for extensive operation at the Phoenix-Comstock group, that recently passed to Jesse Knight and associates of Salt Lake. Sinking will start as soon as the new equipment is in place.

The Mexican company is preparing for vigorous work on the 2900-ft. level. On the 2600-ft. level of the Union Con., a rich streak is being mined from the east winze, and shipments are going to the Mexican mill. Old drifts are being re-opened on

the 2000 and 2300-ft. levels and a vigorous campaign of prospecting has been arranged.

Virginia City, March 20.

NEW MEXICO

GRANT COUNTY

(Special Correspondence.)—Negotiations are in progress for the purchase of the Royal John mine, 18 miles east of Santa Rita, in the Black Range. The prospective purchasers are represented by D. C. Jackling. This probably means another big Guggenheim property in New Mexico. Engineers are unanimous in the opinion that the Royal John and adjoining properties should make one of the great lead-zinc mines of America. —The Republic mine at Hanover is developing a splendid orebody of high-grade zinc-blende on the 100 and 150-ft. levels. This mine is still a prospect, but a good one.—The United States Copper Co., at Hanover, has resumed operation, after having purchased the Hardscabble group of claims at Pinos Altos; also the Davidson saw-mill near Pinos Altos. The work done thus far has been of a preliminary character, no ore having been broken.—The Hanover Copper Co. is said to have a great deal of calamine in sight. This is the property successfully leased by Becker, Hanraty, and Thomas last summer.

George Bethune is examining the Davidson property one-half mile north of Fierro. This mine has produced within the past year over 100 cars of copper ore, 65 cars of which ran above 7%.—The Colorado Fuel & Iron Co. is installing a compressor at the Cupulo iron mine at Hanover.

Hanover, March 20.

SOCORRO COUNTY

(Special Correspondence.)—On March 1 The Oaks Co. paid its fourth consecutive monthly dividend of 1% on outstanding preferred stock.

The shaft on Johnson mine is now down 400 ft., with stations and levels at each 100-ft. point. Ore has been exposed for the entire depth. A small compressor will be installed at once, all drilling thus far having been done by hand. A gasoline hoist is used. The property is owned by Socorro Mining & Milling Company.

The North drift from the 50-ft. level in the Eberle mine continues in ore and a shipment to custom mill will be made soon.

A cross-cut is being driven from the adit level on the Clifton mine to determine the location of the foot-wall. This is part of the Queen Vein system of the district and the vein is of mammoth proportions for a greater part of its extent.

The Mogollon Mines Co. is working steadily on the tailing flume down Silver creek. The better weather will expedite the installation and the terminus, at impounding dams on Mineral creek, about three miles below, should be reached this spring.

At the Maud S. mine The Oaks Co. is cleaning out old drifts and getting ready for extensive development. The property was recently taken under bond and lease. It has produced around one million dollars and a great extent of virgin ground remains to be explored, in which there is reason to believe will be found ore as good as that which afforded the mine's past production.

Mogollon, March 20.

OKLAHOMA

TULSA COUNTY

TULSA. On March 17 one of the biggest deals in mining leases ever consummated in the district was closed when J. R. Cole and associates of Tulsa paid \$300,000 for the transfer of first leases on 240 acres near Tar river, held by Temple Chapman, Greenville Chapman, O. Longacre, and Dan Sullivan.

Mr. Cole and his associates have been interested in second leases on the land upon which they now have obtained the first leases. They also have other interests in the Miami field, having only last week paid \$55,000 for the Red Eagle mine

near Century. On the 240-acre lease sold yesterday, ten lessees are operating and rich mines have been developed. Five large concentrating plants already are in operation and three more are being considered. The mills in operation are the Bethel, Croesus, Tar Creek, Lucky Bill, and Lucky Junction.

The Chapmans, Longacre, and Sullivan took over the lease three years ago. They put down about 100 drill-holes and proved up ore deposits thoroughly.

Two hundred acres of the property is leased out from the land-owners at 8% and the sub-lessees are paying 15%. On the forty-acre tract the first lease is for 15% and the sub-lessees pay 20%. This tract is known as the Cornfield lease and on it are situated the Lucky Bill and Lucky Junction mines.

OREGON

JOSEPHINE COUNTY

The W. & O. Mining Co. of Seattle, has applied to the California State Water Commission in two separate applications for permission to appropriate the waters of the west fork of the east fork of the Illinois river, in Del Norte county, tributary to the Rogue river in Oregon. It is proposed to carry the water back again into Oregon where it is to be used for hydraulic mining on the Osgood claims, near Waldo, the proposed ditches and flumes being 9½ miles long. A total of 230 cu. ft. per second is asked in the two applications. It is proposed to construct two dams across the stream and these with the other works have an estimated cost of \$30,000.

VIRGINIA

The Copper Corporation has been organized to exploit copper deposits at Shawville. E. D. Miller is president, and S. C. Snead, is secretary and treasurer.

WASHINGTON

FERRY COUNTY

(Special Correspondence.)—The following shipments of ore from Republic are reported for the week ended March 15: From the Knob Hill mine, 210 tons, and by the Northport Smelting & Refining Co., 290 tons.

The Lone Pine-Surprise Consolidated Mining Co. contractors have finished sinking the shaft and sump on the Last Chance mine to a depth 530 ft. and cut the vein, 7 ft. wide—all in ore that averages \$16 per ton. The company is now cutting out a station on the 500-ft. level and when this is completed will break ore for shipment to the smelters.

It is reported that the Ben Hur, San Poil, North San Poil, and Trade Dollar mines have been taken under option by an Ohio syndicate.

The Tom Thumb Mining Co., having the Tom Thumb and Rebates mines under lease and bond, reports a great improvement in the Tom Thumb mine, where a shoot of ore has been found richer than any ever before encountered in that property. The company is breaking ore which it will ship on March 15 and hopes to maintain shipments of 150 tons weekly. The working force on this property will be increased.

Republic, March 14.

WYOMING

NATRONA COUNTY

CASPER. Plans have been perfected for an amalgamation of all interests in the Pilot Butte oil-field with the Hall Oil Co., the largest producer at present, as the nucleus of the combination. The Hall company has a daily production of 2000 barrels of oil from seven wells, all of which are shallow. Interests identified with the Midwest Refining Co., the Imperial Oil Co. of Canada, and the Burlington Railroad Co., are involved in the new plan. Under the new arrangement a deep well is being drilled, and in the event that this well proves the existence of oil at depth, the deep drilling of the entire Pilot Butte district will be pushed with vigor. The new interests have guaranteed to build a three-inch pipe-line from

the field to Riverton, on the Chicago & Northwestern railroad, if the lower strata of the sand do not yield oil in commercial quantities, while if a pool is discovered at depth, a six-inch pipe-line will be laid to Bonneville, on the Big Horn division of the Burlington railroad, whence the crude oil may be shipped to either Casper or Greybull for refining.

The new owners have an option on 1,100,000 shares of the stock of the Hall Oil Co., now held by the original underwriters, and have taken options on other properties in the same district.

(Special Correspondence.)—Ore is being shipped from the Del Paso mine in Copper Mountain district, to the smelters at Omaha. The ore averages 17% copper.

Casper, March 10.

PLATTE COUNTY

Within a few weeks, Edward Manion of Lead will commence the execution of a contract with the Great Western Sugar Co. for the delivery of 180,000 tons of limestone yearly, for a period of two years, says the *Lead Call*. The details of the agreement have been decided upon and the contract signed. The rock is to be taken from a quarry near Guernsey, Wyoming, and has been found to be of a quality peculiarly suited to the requirements of the sugar company, in connection with their manufacturing process.

CANADA

BRITISH COLUMBIA

The Hedley Gold Mining Co. (Nickel Plate mine) has declared a dividend of 3%, and an extra dividend of 2%, payable March 31, to stockholders of record at 12 o'clock noon, March 24.

SANDON. The orebody struck recently in the Silversmith vein of the Slocan Star Mines, Ltd., has been followed by drift for 100 ft. on the tenth level, says Oscar White, superintendent. It has a width of 14 ft. In addition to ore of a good milling grade it contains much silver-lead ore of a high grade. Operation of the mill has been proceeding steadily since Sunday of last week. In the first three days a carload of lead concentrate was produced.

Enough water to generate electric light for the town of Sandon has been supplied by laying 1400 ft. of wooden pipe-line between the dams of the two corporations. The pipe-line delivers the overflow in an eight-inch stream. The arrangement permits operation of the Slocan mill on a basis of a shift a day, at which rate milling will be continued until the water supply is increased, which is expected to be soon.

KOREA

(Special Correspondence.)—The Seoul Mining Co., operating the Suan Concession in Whanghai province, Chosen, reports the following results for the month of January, 1917: Total recovery, \$119,955. Both mills lost five days because of stolen power-line. The Tul Mi Chung mine continues to improve. New orebodies found in No. 1 tunnel assay well above the average and the possibilities are excellent. Several prospects continue to develop ore.

Seoul, February 15.

MEXICO

Owners of idle American mining properties in Mexico may yet obtain exemption from General Carranza's recent confiscation decree if they file immediately with the Carranza government their reasons for not resuming operations and make application for extension of their concessions. Ambassador Fletcher has notified the State Department that he had been assured such applications would be granted if accompanied by the proper data regarding the property in question and by a statement of how soon mining work, interrupted by the revolution, can be resumed. The ambassador said, however, that it was imperative for applications to be filed immediately if confiscation is to be avoided.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

H. C. HOOVER has returned to Europe by way of Spain.

W. J. ELMENDORF has returned from Denver to Seattle.

W. ROWLAND COX has returned to Mogollon, New Mexico.

JOHN C. RALSTON, of Spokane, has been in San Francisco.

WILLIAM W. MEIN is here on a short visit, from New York.

SCOTT TURNER is in Bolivia, but expects to return home soon.

ELLSWORTH DAGGETT, of Salt Lake City, is in San Francisco.

STEWART RAWLINGS has returned from the San Luis mine, Durango, Mexico, and is now at New York.

GARDNER WILLIAMS, who has been in San Francisco for several months, is returning to Washington, D. C.

GEORGE B. BUTTERWORTH has returned from New York to Aroa, in Venezuela, where he is manager for the South American Copper Syndicate.

VICTOR C. ALDERSON has taken JOHN M. BAKER and HAMILTON W. BAKER into partnership with him, the firm to be known as Alderson, Baker, and Baker.

JAY LONERGAN has resigned as professor of mining in the Peking Government University and expects to return to America and resume active practice.

CHARLES E. BUNKER, at one time superintendent of the Keystone mine, has been appointed superintendent of the Bunker Hill mine near Amador City, California.

J. W. WHITEHURST has resigned as general manager of the Candelaria mines, at San Dimas, in Durango, Mexico, in order to recuperate. He is now at Salida, Colorado.

EDGAR A. COLLINS sails on April 12 by the 'Tenyo Maru' for Yokohama and Vladivostok, on the way to the Altai, where he will be manager of the Ridder mine, of the Irtys Corporation.

E. K. SOPER and R. R. GOODRICH, professors of mining and metallurgy at the University of Idaho, have been appointed consulting metallurgists for the United States Bureau of Mines.

JOHN H. BANKS, of the late firm of Ricketts & Banks, announces that his son, HAROLD P. BANKS, has been taken into partnership. The address of the new firm of John H. Banks & Son will remain at 61 Broadway, New York.

Obituary

LEBUEUS H. MITCHELL died at the National Soldiers Home, near Los Angeles, California, December 11, 1916, aged 83 years. He was a graduate of Union College, Harvard University, 1865; and later took a course in mining, metallurgy, and geology at Freiberg, 1866-'67. He was appointed Professor of Mining, Engineering, and Metallurgy at Cornell University in February 1868, and resigned in the autumn of the same year to take up journalism in New York. He was editor and manager of industrial journals in New York from 1868 to the autumn of 1873. He served two years in the Civil War as topographical engineer on the staffs of Generals Hooker and Mead. He went to Egypt in September 1874, and until November 1881 served the Egyptian government as geologist, mineralogist, and engineer. Again, from March 1886 to July 1888, he explored the petroleum regions of the Red Sea and conducted drilling operations for the Egyptian government. Under the Garfield-Arthur administration, November 1881 to May 1885, he was connected with the office of U. S. Consulate at London, and for six months was Acting Diplomatic Agent and Consul-General for the United States at Cairo. In the late nineties, he spent two and one-half years in Central America as geologist and mineralogist for an English mining syndicate, where he did scientific work of a high character. Aside from the foregoing, he did much other professional work in this country and abroad.

THE METAL MARKET

METAL PRICES

San Francisco, March 27.

Antimony, cents per pound	24
Electrolytic copper, cents per pound	38
Pig lead, cents per pound	9.50—10.50
Platinum, soft and hard metal, per ounce	\$105—111
Quicksilver, per flask of 75 lb	\$115—120
Spelter, cents per pound	13
Tin, cents per pound	50
Zinc dust, cents per pound	18—20

ORE PRICES

San Francisco, March 27.

Antimony, 50% metal, per unit	\$2.00
Chrome, 40% and over, f.o.b. cars California, per ton	18.00—20.00
Magnetite, crude, per ton	8.00—10.00
Tungsten, 60% WO ₃ , per unit	17.00—17.50
Molybdenite, per unit for MoS ₂ contained	40.00
Manganese, 50% (under 35% metal not desired)	29.00
Manganese ore, 40 to 45%, sells f.o.b. Chicago at 58c. per unit with a penalty of 50c. per unit for more than 8% silica.	

EASTERN METAL MARKET

(By wire from New York)

March 27—Copper is dull and lower. Lead is steady at 9.50. Zinc is quiet at 10.67 to 10.75 cents.

Antimony: Antimony continues in good demand for spot deliveries and prices are now 32 to 33c. for spot, with forward quotations, according to position, ranging from 15½ down to 14½c. Needle antimony has again been sold for shipment at 9¼c. and spot delivery at 12c. Antimony ore remains exceedingly scarce with practically an impossibility to get freight from South America. The nominal quotation is \$2.30 per unit for shipment with \$2.60 for spot delivery asked and maintained.

COPPER

Prices of electrolytic in New York, in cents per pound.

The stock of silver in Bombay on March 1 consisted of 2400 bars. The stock in Shanghai on February 24 consisted of about 27,800,000 oz. in sycee and \$17,100,000, as compared with about 25,000,000 oz. in sycee and \$17,100,000 on February 17.

Statistics for the month of February are appended:

Highest price, 38 7/16d.; lowest, 37 5/16d.; and average, 37.742d.

The 'Metal Bulletin,' under date of February 27, 1917, states that "according to the estimate issued by John McLeish, of the Department of Mines, the production of silver for Canada during the calendar year 1916 was 26,000,000 fine ounces."

ZINC

May	39.28	49.10	
June	40.26	42.07	

ORES

Tungsten. More domestic than foreign buying features the market and considerable quantities of concentrate have changed hands at \$17 per unit. There are numerous foreign inquiries. The alloy ferro tungsten, has sold at \$2 and lower per lb. of contained tungstic acid. Arrivals of the ore the past week have not been large.

Molybdenum. Some of the orders for ore are not to be completed because of late deliveries, and this has eased the market. About \$1.80 per lb. MoS₂ instead of \$2 last week has been offered for the best grade of ore.

Eastern Metal Market

New York, March 21.

All the metals are dull except tin, some of them being lower and some nominal. Copper is dead with little business being transacted. Zinc is still stagnant though a little lower, the volume of transactions being small. Lead continues to assume an easier tone so that spot demand has been nearly eliminated. Tin is strong and higher because of an advancing market in London. Spot antimony is scarcer and higher, being nominal at 32 to 33 cents.

In the steel market prices continue to advance. International affairs have been a large factor in this because foreign demand shows no let-up and this has stimulated domestic covering. Pig-iron continues to go up, the increase this last week having been from \$1 to \$2.50 per ton. Sales have even been made for first half of 1918. The statement of the Steel Corporation for 1916, issued today, shows the remarkable surplus of over \$201,000,000, against \$44,000,000 for 1915.

COPPER

The most interesting feature of the week in an otherwise featureless market was the announcement yesterday that the leading copper producers had sold over 45,000,000 lb. of copper to the United States government at 16.6739c. per lb., which is from 20 to 14c. below the present prices for the specified deliveries. The metal is to be delivered in approximately equal quantities each quarter from April, 1917, to April, 1918, the Navy taking 20,000,000 lb. and the Army 25,510,000 lb. The delivery is to be in regular shapes at Atlantic seaboard points. In a public statement the sellers say:

"We offer the copper at this price notwithstanding our costs for labor, materials and supplies, etc., vary from 30 to 75% above the average during the 10-year period because we believe it to be our duty to furnish the requirements of the Government in preparing the nation for war with no profit more than we receive from our regular production in normal times."

The strike at the Laurel Hill refinery of the Nichols Copper Company is still effective and is interfering with production and deliveries. This week smaller strikes elsewhere are delaying both February and even March shipments so that it is not unlikely that some consumers and buyers may have to go directly into the market. The entire market is slow and lacks snap and life. A little business has been done each day but the volume has been small. A week ago today a slight softness developed but the tendency now is stronger. Prospects of war are likely to further strengthen the market. The quotation yesterday was 35.75 to 36c., New York, for electrolytic for early delivery with second quarter metal at 34 to 35c., third quarter at 31 to 32c., and fourth quarter at 30 to 31c. The London market is unchanged at £151 for spot electrolytic. Information as to exports is withheld from the public until further notice, by order of the Government.

LEAD

The feature of the market is the continued large arrivals of lead which have been held up in transit from the West and which began to come more freely a week ago. These receipts have been so general that they have practically stopped the demand for spot metal which last week was as high as 10c. and is now as low as 9.50c., New York. Generally all buyers have shared in these large arrivals, some to such an extent that they have more than they need and have offered some for sale. These conditions have caused the market to ease off and have dispelled the anxiety that was prevalent less than two weeks ago. The threatened railroad strike caused some uneasiness, but its elimination will relieve still more freight

congestion and it is predicted that prices will be lower rather than higher. The quotation for prompt March shipment is 9.50c., with April at 9.25c. and May at 9c. The London spot-price is £30 10s., unchanged from a week ago. It is stated that producers in general are not at all alarmed for the reason that the spot-price has softened because production, since January 1, 1917, has not been up to the mark, so that futures are likely to hold strong.

TIN

The outstanding fact as well as the surprise of the market has been the sharp advance in tin in London the past week. Spot Straits tin, which a week ago yesterday was quoted at £201, is now £214 2s. 6d. and spot standard metal is now £214 against £201 15s. last week. Even future standard tin has advanced decidedly, being quoted yesterday at £213 against £200 5s. a week ago. The causes for these sensational increases are practically all guess work on this side. Prominent importers here seem to be strangely uninformed by their London connections. The explanations that are being offered is that possibly an income tax on exports of tin from the Straits has been put in force or is about to be, or that a vessel carrying a large cargo of tin has been sunk, which information the British authorities may be keeping from the public. The effect on this market has been to make it much stronger, whereas a week ago it was dull. Sales have not been large in the past week, perhaps 400 to 500 tons in all. After a dull day, last Wednesday, the market became more active on Thursday when spot-metal sold from 52.87½ to 53.50c., most of it going at the latter price. Monday and Tuesday of this week the market became much stronger, about 100 tons changing hands on Monday, the price yesterday advancing to 56c. for spot metal, against 53.50c. a week ago. The tin arrivals are reported as 1585 tons with 3791 tons afloat. Imports of tin at Pacific ports in January, 1917, were 1,471,729 lb. at San Francisco and 3,350,161 lb. at Seattle, with a total valuation of \$1,804,256.

ZINC

The market is weaker than it was a week ago, due to the activities of some of the weaker interests that do business anyhow on some scale. Very little buying has been reported and the market as a whole is dead. Definite bidding appeared yesterday at 10.50c., St. Louis, for spot spelter, and this may be regarded as the spot or nearby quotation which is 10.67c., New York, and nominal. As long as the ore-market is high and the spelter-market weak, the tendency will be dull. Galvanizers are doing nothing and there is practically no demand now from the brass interests. The April quotation is about 10 to 10.12½c., with second quarter at 9.50 to 9.75c., both St. Louis. The market cannot be regarded as weak, but as easier and dull. Zinc ore is reported as a little lower but not enough to have any effect.

ANTIMONY

Because of the continued holding up of shipments of Chinese and Japanese metal on the way from the Pacific Coast, the spot-market is higher. The quotation is at least 32c., nominal, and it is said offers of 33c. have brought out no antimony. Large lots are unobtainable. Metal for delivery in New York in March has been sold at 29c. for small lots. Futures attract little attention, shipments from the Orient being quoted at about 15c. for March and 14.25c. for April. Needle antimony has sold for shipment at 9.25c. and for spot delivery at 12 cents.

ALUMINUM

The market is unchanged from last week and the nominal quotation remains at 58 to 60c. per lb. for No. 1 virgin aluminum, 98 to 99% pure.

EDITORIAL

T. A. RICKARD, Editor

AT the moment of going to press the message of the President is published. We deem it sufficient at this time to quote a small part of the message, as expressing the high purpose of our people. "Our object is to vindicate the principles of peace and justice in the life of the world as against selfish and autocratic power, and to set up amongst the really free and self-governed peoples of the world such a concert of purpose and of action as will henceforth insure the observance of those principles. Neutrality is no longer feasible or desirable where the peace of the world is involved and the freedom of its peoples, and the menace to that peace and freedom lies in the existence of autocratic governments backed by organized force, which is controlled wholly by their will, not by the will of their people. We have seen the last of neutrality in such circumstances. We are at the beginning of an age in which it will be insisted that the same standards of conduct and of responsibility for wrong done shall be observed among nations and their governments that are observed among the individual citizens of civilized states. We have no quarrel with the German people. We have no feeling towards them but one of sympathy and friendship. It was not upon their impulse that their Government acted in entering this war. It was not with their previous knowledge or approval. It was a war determined upon as wars used to be determined on in the old unhappy days when people were nowhere consulted by their rulers and wars were provoked and waged in the interest of dynasties or of little groups of ambitious men who were accustomed to use their fellow men as pawns and tools. . . . Just because we fight without rancor and without selfish objects, seeking nothing for ourselves but what we shall wish to share as free peoples, we shall, I feel confident, conduct our operations as belligerents without passion and ourselves observe with proud punctilio the principles of right and of fair play we profess to be fighting for. . . . It will be all the easier for us to conduct ourselves as belligerents in a high spirit of right and fairness because we act without animus, not in enmity toward a people or with the desire to bring any injury or disadvantage upon them, but only in armed opposition to an irresponsible Government which has thrown aside all considerations of humanity and of right, and is running amuck."

RUMOR was current recently that the Roessler & Hasslacher Chemical Company had filed incorporation papers with the Secretary of State in California looking toward the manufacture of cyanide on the West Coast. The filing of these papers, however, did not indicate an early realization of this purpose. We are able

to state that the new works, necessitated by the withdrawal of power-privileges at Niagara Falls by action of the Dominion of Canada, are in process of construction at Perth Amboy, New Jersey. The primary condition determining the selection of a site was that of rapidity in assembling the equipment, which could be accomplished only in the East. The new plant will be in operation by the end of June.

ENGINEERS and other professional men desiring to serve their country are advised to write to the Secretary of the Institute or to the Adjutant General, U. S. Army, Washington, D. C., for particulars of the service they can render. In our issue of November 18, 1916, we published an article on the organization of an Officers' Reserve Corps. This article, by Mr. A. H. Babcock, gave a great deal of timely information.

ANOTHER engineering society has been organized. The Southwestern Society of Engineers came into being early in March at El Paso. Membership is open to practitioners in all branches of engineering. It is planned to hold at least two conventions every year and to stimulate comradeship among engineers in the Southwest. The meeting on March 8, 9, and 10 was marked by the reading of several interesting papers, including one by Mr. Gerald Sherman, of Bisbee.

HIGH prices for copper are not wholly translatable into large or excessive earnings, as appears from the experience of the Calumet & Hecla. In conformity with the usual practice it has been selling export copper on the basis of commissions, insurance, and freight paid to destination. With ocean-freight 700% above normal, and marine insurance at 10% on the value of the cargo, the cost of delivering copper to foreign buyers is not less than 7 cents per pound. Such extraordinary conditions add to the burdens and uncertainties of custom-smelters in even higher degree.

TIN shipments from Bolivia to the United States are changing the market-conditions for that metal. Normal importations of tin from all sources average about 52,000 tons per annum. In March 1915, the American Smelting & Refining Company undertook the reduction of Bolivian tin concentrate at Perth Amboy, New Jersey, smelting in a reverberatory furnace, and refining electrolytically. The capacity of the plant was 600 tons per month, which has proved to be inadequate. Additional equipment will bring up the monthly production to 1500 tons by July 1. Transference of tin-smelting on such a scale from Europe to this country

will undoubtedly encourage the further development of the sporadic tin deposits in South Carolina, South Dakota, Texas, and other American localities.

RETIREMENT from active life of so prominent a figure as Dr. James Douglas seems like the passing of an epoch. His influence has been part of the up-building of the West, not only in the work of material development but in metallurgical pioneering at the same time. He has been a creator of industry in the best of ways, overcoming the obstacles of the desert, solving difficult problems in practical operation, and establishing new trunk-lines of communication. He now becomes chairman of the board of Phelps, Dodge & Company, relinquishing the presidency to his son, Mr. Walter Douglas, and also turning over the presidency of the El Paso & South Western Railroad to other hands. Dr. Douglas is the recognized dean of American mining engineers, to whom individually and collectively he has always been a friend and an inspiration.

DISCUSSION this week includes a letter from Dr. Otto Sussman, a mining engineer of high standing, who takes exception to an item of news appearing in one of our recent issues and sent to us by our correspondent at El Paso. We are glad to publish the correction. Mr. W. R. Cramer, an experienced metallurgist, contributes an interesting note on the use of caustic soda in flotation. The use of this chemical as a deflocculant in the old Dominion mill is suggestive. Mr. Edward Thornton writes, from Arizona also, to describe his method of sampling a large low-grade orebody, valuable for its copper content. The notes he furnishes will be appreciated by other mining engineers, particularly the drill-holes traversing the ore to be sampled in V-shaped series. Mr. E. H. Wedekind expresses himself concerning the Hall sulphur process and thereby furnishes a useful warning. We hope that further information concerning trials of this process now being made at Mount Lyell, in Tasmania, may be forthcoming.

OUR correspondent at Johannesburg, reviewing last year's results of mining on the Rand, refers to an attempted improvement of the grade of the ore hoisted from the Crown Mines by decreasing the width of stoping. This proved disappointing. Evidently the pendulum of change has swung pretty violently since the days when the managements on the Rand chased the lure of low cost per ton in disregard of the fact that the profit per ton is the immediate aim of sagacious mining and the total profit on the mine as a complete operation is the object of a far-seeing owner of such property. It has been discovered, in London and at Johannesburg, how little a low cost per ton necessarily contributes to the amount of the dividends, if a low figure of cost is concomitant with a low yield of gold, that is, if tonnage be gained at the expense of grade; so now an effort is made to improve the grade, reduce the tonnage, and increase the profit per ton. This is a proper policy, when not car-

ried to the point of spending more energy in discarding waste than is incurred in putting the waste through the mill. Moreover, the former scramble for tonnage has caused the erection of big mills and a demand for an output that some of the mines now find it difficult to supply. The clever men on the Rand have made some big blunders mainly because the policy adopted by them was shaped to please the exigencies of the share-market rather than to face the realities of technology and of conservative management.

ONE of the problems presented by the increasing application of flotation to ore-dressing is the treatment of the product, a watery concentrate containing oil. To Mr. Robert S. Lewis, Professor of Mining in the University of Utah, we are indebted for a timely and most interesting discussion of this subject. Our readers will recall with pleasure other writings from his pen, and will find in his latest article those evidences of literary skill and scientific observation that combine to make his contributions to technology so welcome. Indeed, no subject is more interesting just now than the disposal of flotation products—there is so much and so many of them! A great demand exists for information concerning either the preparation of them for shipment to the smelter or for their treatment in the locality where they are made. Professor Lewis discusses first the dewatering of the concentrate, and in this connection he speaks concerning the moisture permissible in flotation-concentrate to be transported on ships. While no definite proportion of water is specified, it appears that the concentrate must not be sloppy; it must be firm enough not to go awash. Different methods of draining the concentrate before shipment are described, including filters, thickeners, drying-floors, vacuum-pumps, and steam-pipes. A large number of examples of successful filtering are recorded, with practical details of the utmost usefulness. The next difficulty is the smelting of the concentrate, the increasing output of which, as our readers are aware, has made so great a demand on reverberatory furnaces as to diminish the relative utility of the blast-furnace in copper smelting. This difficulty, of course, is physical, not chemical, due in part to the wetness but more largely to the fineness of the material. Sintering of the concentrate before reduction in the blast-furnace is a step no metallurgist likes; at best it is a dirty and inefficient process. Therefore reverberatory practice is preferred. This applies to lead and copper products; the zinc smelter finds troubles of his own. Drying in kilns and roasting in muffles or in open-hearth furnaces are among the preparatory methods adopted. Loss in dust is the chief bugaboo. No wonder the smelter superintendents call this new metallurgical product "a damned nuisance." But more and more of it is going to be produced in the near future, therefore it remains for the skilful technician to accept the situation and make the best of it, as, of course, he will. The examples of smelting practice given by Professor Lewis are peculiarly interesting.

David H. Browne

With infinite regret we record the death of David H. Browne, who, on March 30, succumbed to complications following an attack of influenza. He could little be spared at any time, least of all today, for he was an engineer that gave expression, in his life as in his writings, to the highest ideals of the profession—to those ideals that make the engineer an intelligent, patriotic, and clear-sighted citizen. David Browne was born an Irishman and came to the United States when a boy of sixteen. He graduated from the University of Michigan and began his professional career at the blast-furnaces of Ohio. In 1891 he entered the service of the Canadian Copper Company and since then he has been identified with Canadian metallurgical practice. In 1916 an honorary degree was conferred upon him by Queen's University, at Kingston, this event serving to mark his high place among the most thoughtful and responsible members of the engineering profession in North America. During the last twelve months he contributed several characteristic articles to the bulletins of the Canadian Mining Institute, and in all of these he showed the combination of idealism, good sense, and humor that made him so lovable a character. In our issue of March 27, 1915, we published the text of a speech made by him on the occasion of a medal being presented by the Mining and Metallurgical Society to Mr. Robert H. Richards. The present writer heard that speech; it was a splendid appreciation of a man after Browne's own heart, and he, in expressing his admiration of the medallist, gave voice to his own notions of service and of conduct. The tribute to his friend was worth more than any gold medal. On that occasion he said: "The greatest thing in life is personality. The greatest men are those whose fingers find the chords of life and at whose touch we thrill in sympathy." He touched those chords, he struck a strong clear note, and the echo of them shall not willingly be let die.

Group-Insurance

Esprit de corps! That is at the bottom of the recent remarkable development of group-insurance. It intensifies the consciousness of co-operative effort on the part of capital and labor toward an economic result, because of the proportionate benefit that it yields to the several participants. It thus becomes a true vitalizer of industry. The action of the American Smelting & Refining Company in undertaking to carry such insurance for its employees in a most notable instance in the mining world in which this later phase of profit-sharing has been adopted. During the year 1916 the company paid \$31,000 in premiums for group-life insurance covering the lives of all day-laborers who had been continuously on the pay-roll for one year or more at eight plants. The company has now made the plan general throughout all of its mines, mills, and metallurgical works in the United States, and has assumed the liability on its own

account, issuing certificates to every workman, regardless of race, age, or physical condition. The single requirement is continuity in employment. This adopts the essential feature of the plan of group-insurance that commended the system so promptly to the acceptance of both employee and employer; it is reward for service, not a bonus, nor a gift; it has nothing to do with profit-and-loss accounts; it does not fluctuate with the market; nor may it be minimized by absorption of corporate earnings in ways known to the financier. It avoids the common pitfalls of profit-sharing devices wherein the wage-earner is thrust into the position of a partner without a voice in the management, yet subject to shrinkage of income in the face of decreased earnings set forth in the balance-sheet that he but dimly understands and quite frankly distrusts. Behind all this lies the lack of education in the wise uses of income that has militated against the success of profit-sharing. Teaching to save is barren of results compared with instruction in necessary and productive expenditure. As between saving and growth the difference is antipodal. The appeal of group-insurance lies in its recognition of the value of continuous service *per se* and in the rights to the cumulative inherent benefits; it has caught the imagination of that vast majority that has laid up nothing for the future nor made provision for the welfare of wives and children when death shall cut off the daily wage. Insurance statistics show that 89% of all men at death leave nothing behind. To these people the insurance certificate offers a new ideal: protection to the family through steady devotion to duty. The plan adopted by the great smelter corporation is practically identical with that developed by the Equitable Life Assurance Society, on the basis of which group-insurance for various corporations is being carried for an aggregate sum of over \$100,000,000. The Union Pacific Company alone has taken out \$35,000,000 of such insurance this year for the benefit of its employees.

Effective from January 1, 1917, the American Smelting & Refining Company obligates itself to pay to the heirs of an employee dying while enrolled in its service the sum of \$1000 in the case of a married man, and \$500 in the case of a single man. The term of the certificate is one year only, but at the end of each year for the ensuing five years new certificates will be issued, increasing the amounts of the indemnity \$100 and \$50 respectively, until the indemnity of married men will be \$1500 and that of single men \$750. This applies to wage-earners alone. The salaried employees receive certificates of indemnity in sums equal to one year's salary in each case, with a maximum limit of \$10,000. The company will set aside sums each month to create a fund sufficient to carry the indemnity after the manner of the legal reserve in ordinary insurance, but the wage-earners' indemnity will be taken up in the general expenses of each plant. It would, therefore, seem to be the purpose of the company to re-insure continuously the wage-earning group with the regular insurance companies that take this class of risk.

The principle of group-insurance is similar in some respects to that of fire-insurance. The risk is of short duration; the law of averages applies by taking the age-factor into account, irrespective of physical condition. The estimate of the liability is revealed from the rate charged by insurance companies, this being approximately 1½% on the annual pay-roll, where groups of more than 100 employees are protected. Group-insurance lies apart from so-called welfare-work; it is part of the business program, not of the charity organization, of the corporation. Labor efficiency is said to vary from 20 to 80% of that which might be delivered under the stimulus of the highest interest and resolve of the workers. Average efficiency is rated at 60% of that normal to free-will labor. If this be raised 5% by the issuance of indemnity certificates the gain in productiveness above the cost of such insurance yields a profit to the enlightened corporation utilizing the system, and it increases the assets of the nation in like proportion. The verdict of companies that have had experience with the plan is that an estimated efficiency greater than 5% may be credited to its influence. The certificates develop a new bond between the individual and the social group; for the first time in his life the ordinary wage-earner becomes a creditor, with society voluntarily admitting itself his debtor and putting a bond of indemnity into his hands. In many cases these certificates constitute the only valuable paper the workman has ever owned; it is not uncommon to see them framed and hanging on the walls of the home. Group-insurance has not solved the problem of harmonious co-operation between labor and capital, but it is a long step in the direction of bringing the worker into comprehension of the meaning and value of capital as surplus labor stored for use and as a provision against future calamity or want. Esprit de corps, the group interest, the group effort—this is the foundation of solidarity in human endeavor. In group-insurance this important principle is operative, and this commends it as one of the most practical advances in the rational socialization of industry.

State Mining

If a proposal were made to operate the copper mines of the Keweenaw peninsula under the direction and for the benefit of the State of Michigan or to exploit the gold mines of the Mother Lode region in the interest of the State of California, what would you think of it? This question is prompted by the fact that a Mining Commission has been in session at Johannesburg to collect evidence concerning the advisability of enacting laws that would authorize the government of the Transvaal to operate the gold mines of the Rand. All sorts and conditions of men have expressed their opinion before the Commission. Mr. F. A. Unger, a consulting engineer, testified that in Holland the idea of State mining was introduced in order "to increase production and to prevent foreign capital getting too big a hold." He thought that "in an unsettled country like South

Africa there is danger of political jobbery." That might happen in Michigan or California. We cannot conduct our State Mining Bureau without "political jobbery," can we? Mr. Unger said that "State mining in Holland was brought about by necessity, but no such necessity exists" in the Transvaal. Luckily, no such necessity exists in Michigan or California. Messrs. Evans and Ross, speaking for mine employees, said that "technical brains are just as available to the Government as to private employers if it pays the necessary salaries." Governments do not pay the salaries necessary to retain such men as are at the head of big speculative or industrial enterprises. The brains gravitate rather to Wall Street than to Pennsylvania Avenue. The manager of the United States Navy is not to be compared in mental vigor with the manager of the Bethlehem Steel Corporation. The restrictions to unlimited gain imposed by Government service are uncongenial to the keen and energetic type of man who usually directs the operations of a big mining or smelting enterprise. The same witnesses asserted that "greater security of tenure of employees would be an incentive to good service." Not in this world as now constituted. Insecurity of tenure prompts most men to work hard in order to win approval from their employer or chief. Sir George Albu, an experienced administrator of mines, was emphatic in his opinion that "the working companies so far have greatly benefited the country—more than the State could. The companies have benefited the country more than themselves." If they have, it was unintentional, one may be sure, for the big mining corporations were not organized on a philanthropic or even a social basis. The social instincts of individual operators, like Eckstein and Taylor, or the big political ideals of sundry financiers, such as Rhodes and Beit, were no part of the scheme of mining, which was to make money for shareholders in England, Germany, and France. "Mining is always risky," continued Sir George. That is true, and it is a truism that the State would be prompt to recognize. Indeed, the State would not be likely to take the risks that the individual or the syndicate faces willingly. State mining is bound to be timorous because State officials would not be in a position to indulge in speculative ventures to the same degree as the promoters and adventurers to whom the expansion of mining is largely due. The dread of criticism from an untechnical public would paralyze the initiative of a State director of mining and his coadjutors. "If the State were to mine, a good many political followers would have to be considered." Yes, we can tell Sir George that even a State Mining Bureau or an office of State Geologist cannot be conducted without considering political followers. As now organized such bureaus are of minor importance, but if they were to be given the authority to control the mining of the State, what would happen? The mere imagination of the consequences is a nightmare of political wire-pulling and subservience. On the Rand, Sir George Albu predicted, it would mean a demand by the labor-unions to expel the Kaffirs from the mines and to employ white labor only.

"That would spell absolute failure," he added. His opinion of State mining was summarized in a proverb: "Fools rush in where angels fear to tread." He testified that the 'mining houses' had sold their shares, which had been absorbed largely by the public in South Africa. "The Rand is not paying more than 10%. Without speculators there will be no mining business. The advocates of State mining do not appreciate the dangers and difficulties." He quoted large expenditures on mines that had proved unprofitable, but he had not much to say concerning the big 'killings' made by himself and other promoters in the halcyon days of the Rand when shillings were turned into pounds by lucky speculators—"not 'gamblers'," Sir George interrupted heatedly when somebody present referred to "investors in mining ventures" as 'gamblers'—so says the report of the proceedings. We agree; they are neither 'investors' nor 'gamblers,' but 'speculators' in a necessarily venturesome business, and if their methods are not always legitimate that is not a defect inherent in mining, but in the sort of people to whom mines are counters in a game that is not always played fairly. Mr. E. F. Bourke, of the Pretoria Chamber of Commerce, thought that "gold mining is too risky an undertaking for the State." He said that "the tendency of State mining will be to make mining industrial and eliminate the speculative element." That would kill it; the vitality of mining depends upon the red corpuses of adventure; the exploratory instinct is essential. When mining becomes industrial it is senile. Mr. C. F. Tainton suggested that in South Africa the limits of private mining had been reached. The ground remaining undeveloped offered too small a margin of profit for private enterprise. Was the gold to be left in the rock for all time? If private capital demanded 9% return above the 10% profit-tax, it would refuse to work such areas, while the State, which could work advantageously for 4% and the return of its capital, would have a margin of 5 shillings per ton—or enough to bring immense new areas within the requirements of profitable exploitation. Indeed, the State could afford to work without profit, because so large a part of the money spent would remain in the country and become subject to taxation. The verdict of competent engineers, said Mr. Tainton, was that within eight years only 33 of the existing mines would be producing gold and within fifteen years the output will have fallen to less than £20,000,000 per annum, or about one-half what it was in 1916. The value of property in South Africa will decline "hundreds of millions" of pounds, if the chief industry of the country is not supported. In ten years, added Mr. Tainton, there has been a drop of 40% in the value of property around Johannesburg. Mr. Kenneth Austin thought that the work now required to develop a group of claims of suitable size involved too much capital for any company of citizens; it should be undertaken by the State. At least "the State should do some of the heavy work, and the citizen could do the remainder." The State Mining Department should be organized like the existing State Railway Department, he thought. As to the suggestion

that it was better that the individual should bear the loss incurred in mining than that the State should suffer, he insisted that "the loss is an economic loss, whether borne by a State or a person; no sophistry could obscure the fact that £500,000 wasted in digging useless holes was an economic loss and the net effect the same." Of course it is; the labor that is spent unproductively is squandered.

Mr. D. Wilkinson, consulting engineer, considered the proposal "utterly nonsensical." Mr. Henry Adler was anxious to see the mines owned and operated by residents, he would like to see the Government raise capital in South Africa for working two promising areas, which he defined, and it was his belief that the workers would invest in the debentures issued for such a domestic enterprise. Mr. William Hosken, a merchant, quoted the axiom that "the national estate should be used to the best advantage"; therefore he favored State mining. If the whole area were exploited, mining risks would be reduced to a minimum, he said; and so would be the profit, we suggest. He recognized the difficulties and specified "gerrymandering, excessive wages, political power of voters so engaged, Government 'stroke'," meaning by this last the deliberation that marks the work of a Government employee. Being an optimist, he thought these evils could be corrected. Most of us do not. The administration of the State Railways in South Africa does not encourage such expectations. Mr. Hosken argued that the State could obtain capital at a lower rate of interest, say, at 6%. So it could, but it would endanger its credit by engaging in essentially venturesome business on such a low return. The same witness suggested that the profit from State mining should be used to reduce the national debt, but he is counting his chickens prematurely; if the State exploited the low-grade areas now lying idle—and that is the idea—it would need all the profit in one mine for development in another. The idea of employing convict labor was distasteful. Mr. J. H. Munnick, mining engineer to the former Transvaal republic, said that the late Government worked the Rand as a State mine during the Boer war "with very successful results." By opening up new mines while the old ones were being worked out, the industry would pass automatically into the hands of the State; "it would be criminal to miss the opportunity." Mr. J. G. Lawn, a distinguished engineer, did not think that "would work as well for the Government as for a private company." The pace was quite different. Mr. C. B. Kingston, another mining engineer of high repute, suggested that the State would do better by encouraging new enterprises than by going into mining itself. Engineers in charge of existing State mines found their work hampered by political considerations, leading to the employment of undesirables. "The proper function of the Government was to create, by wise legislation, conditions best calculated to stimulate private enterprise. To use the revenues of the community was to cramp and discourage individual initiative and waste the finest asset a community could possess." Let us leave it at that.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

C. A. Bentley v. American Metal Co.

The Editor:

Sir—We do not ordinarily go to the trouble to deny misstatements which appear in print in the daily papers, but our attention has been drawn to an article which appeared in your issue of February 17 from your correspondent in El Paso with reference to a suit brought there by C. A. Bentley against our company for breach of contract. Your correspondent's report of this litigation is so inaccurate and reflects upon us in such a way that we cannot permit it to pass uncorrected. The facts are, as clearly proved at the trial, as follows:

A contract was made with C. A. Bentley, acting as president of the San Roberto Mining Co., on the one hand, and one H. A. Houser, as president of the Compañía Minera y Compradora de Metales, on the other, for the purchase by the latter of 10,000 tons of zinc ore from the San Roberto mine. Mr. Houser endeavored to sell this ore to the Compañía de Minerales y Metales, Compañía Minera de Penoles, and ourselves, but all of these companies refused to purchase it because of its exceedingly low grade, the material running less than 25% zinc.

Houser then notified Bentley that his company could not handle the ore and that at the time he made the contract in the name of his own company he did so as our agent. When Bentley threatened suit, Houser told him that it would be useless to sue the Compañía Minera y Compradora, as it was financially irresponsible, and that the only way he could recover anything was by joining the Compañía de Minerales y Metales, the Compañía Minera de Penoles, and our company as co-defendants. As a further evidence of the agreement between Bentley and Houser, Houser admitted on the stand that the day before the trial the suit against his company had been dismissed, which was apparently to be his reward for testifying against us.

Each of the defendant companies denied absolutely that Houser had any authority to act for them as agent, and there was not a scrap of evidence offered, outside of Houser's own testimony, to show that any of our companies had made the contract or had authorized any one else to make it on our behalf.

So far as the Compañía de Minerales y Metales or the Compañía Minera de Penoles was concerned, no serious attempt was made to fix responsibility upon either of these companies, the attorneys for the plaintiff only asking to submit to the jury the question of whether or not our company was responsible for the contract which Houser had made. On this question, the jury found

against us and awarded Bentley damages of approximately \$60,000 to cover alleged profits which he would have made had the ore been shipped and paid for under the terms of the contract. No serious fight was made by our attorneys on this question of damages, as they were convinced that there had been an absolute failure of proof to connect our company in any way, through agency or otherwise, with the making of the Bentley contract. An appeal has been taken from the judgment entered on the verdict of the jury, and we have every intention to prosecute this appeal to the highest courts in the State.

We have no desire to try this litigation in the press, nor do we even care especially to have this statement of the facts published. We do care very seriously, however, to have ourselves placed in the proper light in the eyes of the gentlemen who are editing publications, such as the MINING AND SCIENTIFIC PRESS, which reach the hands of so many of our friends in the metal business.

OTTO SUSSMAN, Vice-President,
The American Metal Company, Limited.

New York, March 15.

Caustic Soda in Flotation

The Editor:

Sir—Several letters regarding the use of caustic soda in flotation have appeared recently in your paper. In connection therewith it may be of interest to know that since October 1916, caustic soda, to the extent of 1.3 lb. per ton of solids treated, has been used in flotation at the Old Dominion Copper Mining & Smelting Co.'s concentrator at Globe. The flotation-feed comprises the total mill-slime, consisting of 44% of the mill-feed. This contains on an average of 25% minus 200-mesh material and 75% plus 200-mesh. The mill-feed contains 13% minus 200-mesh material which may be called 'primary' slime. The average analysis of the general mill-slime follows:

	%		%
Cu	2.6	CaO	1.5
SiO ₂	55	S	4
Fe	8	Al ₂ O ₃	17.5

It will be noted that the flotation-feed contains a high content of clayey material. That caustic soda has a marked de-flocculating action is evidenced by (1) the difficulty experienced in the settling of the flotation slime-tailing in the settling-ponds; (2) the lessening of the insoluble content of the flotation-concentrate produced; (3) the increased extraction caused in part by the de-flocculating action on the mineral-content of the

very fine slime. A further benefit obtained in the use of this reagent is its chemical action on the water in the flotation pulp. This water contains approximately from 10 to 15 grains per gallon of bicarbonate of lime, $\text{H}_2\text{Ca}(\text{CO}_3)_2$, and may be called fairly hard water. The addition of caustic soda to the flotation slime-pulp brings about the instant precipitation of finely precipitated carbonate of lime, in accordance with the reaction:

The elimination of this lime carbonate from solution, and the presence of sodium carbonate in solution, unquestionably brings about increased efficiency in the flotation work at this plant. The use and effects of this reagent at the Old Dominion concentrator emphasize the point that in many cases the proper use of acid or alkali is of great importance in the investigation of the conditions best suited for the flotation treatment of any particular ore.

W. B. CRAMER.

Globe, Arizona, March 21.

Sampling Low-Grade Orebodies

The Editor:

Sir—While this is a little apart from your recent discussion on sampling low-grade ore, it brings up an interesting case and a method that I have not happened to see described.

In low-grade orebodies sampling with the moil, even when carefully done, may be misleading unless the deposit is quite uniform. In case the ore occurs as bunches and veinlets through the country-rock, it is quite easy to 'salt' the sample, as frequently the ore is softer than the rock.

In the illustration shown, a proportion of the back of a large stope was sampled by moil, giving an average result of 2.81% copper, this result being checked by several previous moil-records by different engineers. As this block was near the surface it had been stripped and was being worked as a glory-hole, so it was easy to check the actual record obtained by the previous method of sampling. When mine operations were started in this special block the mine-samples had indicated very low-grade, but it was assumed that this might well be a portion of extra poor ground as the stope in any event was most irregular. As the stope was being conducted on a fairly large scale, several hundred tons that averaged 1.77% were mined before deciding to stop the work at that place. It was then decided to check the previous sampling, as the back below was still accessible, and especially as our operations had given a rather startling difference from the sample record.

We wished to do this cheaply and quickly; the ground being hard, moil-sampling would have been slow and expensive, so we decided to try a stoper-drill, which we found to be a cheap and accurate method of sampling low-grade ore. The mechanical arrangement is simply an ordinary stoper with a canvas bag to catch the dust, the bag being held open by an iron fork and the drill

working through a leather washer in the side of the bag and the opening. The method of taking the sample is shown in Fig. 2, each inverted V constituting a sample.

Sulphur From Pyrite

The Editor:

Sir—From the editorial discussion in your issue of March 17 concerning the production of elementary sulphur from pyrite, I am left under the impression that M. G. F. Söhnlein refers to the experiments being made by H. F. Wierum and others of the so-called Hall process, in Australia, which was tried out at the Balaklala Consolidated Copper Co. some three years ago. The manager at that time was Frank M. Leland. Under an arrangement with the company owning the Hall patents approximately \$125,000 was expended on the process, with absolute failure as the result. The only sulphur ever made was due to spraying steam into the McDougall furnaces, producing H_2S , and consequently metallic sulphur, and incidentally nearly suffocating the entire community. They claimed that water-gas made from crude oil was absolutely necessary. A gas-plant was built at a cost of about \$60,000, large enough to serve the town of Redding, and it was standing there when the writer left, a monument of folly, and no doubt it has been sold as junk, as was most of the other equipment at the smelter, under the 'lost and found' supervision. I was employed to assist the manager and did so to the extent of preventing the payment of \$150,000 for the use of this process at that time, and subsequently became the acting manager. To give the history of this abortive attempt would require a volume.

E. H. WEDEKIND.

Battle Mountain, Nevada, March 19.

[The Hall process depends upon roasting pyrite in a reducing atmosphere with the addition of steam, maintaining a temperature of between 600 and 900° C. The object is to oxidize metallic bases without oxidizing the liberated sulphur. This is evolved as sulphuretted hydrogen. By reacting with sulphur di-oxide all the sulphur theoretically should be freed from combination and pass off with the fume in the elemental form. It was collected from the furnace gases by the Cottrell method of electrical precipitation. The Hall patents were acquired by the Sulphur Syndicate, Ltd., of which Theodore J. Hoover became chairman, and the American, Canadian, and Mexican rights passed to the Federal Sulphur Co. The outcome of the experiments in Australia will be awaited with interest. Failure of a new process at one time does not preclude its later development into a useful and economic method.—EDITOR.]

SALT BEDS at Anse la Butte, near La Fayette, Louisiana, have shown a thickness of 3463 ft. of pure rock-salt, beginning at a depth of only 150 ft. below the surface. The deposit was tested by drilling. The Benners Salt Co. is erecting a plant to treat 700 tons daily.

FIG. 2. CROSS-SECTION THROUGH STOPES.

Losses Incident to the Caving of Orebodies

By R. G. SAMPSON

The caving-system has been extensively employed by some of the largest mines in the South-west, and it has played an important part in the extraction of the bodies of iron ore in the Lake Superior region. It is used particularly for the mining of low-grade, uniform orebodies for the reason that a large production may be had at a low cost per ton. That it is not usually applied to the mining of high-grade orebodies is in part due to a loss of ore which invariably attends its use. In the early days of its application it was generally believed that a large percentage of the ore would be lost through the unavoidable mixture of waste with the ore. This difficulty has been largely overcome in some places by the use of a 'timber-mat' that is introduced between the ore and cap-rock. Here the question of cost enters and this feature, in many instances, has been overlooked or misunderstood, as the operators appeared to think that the increased extraction would not justify the necessary expense. To illustrate the following remarks, the draw-

ings, Fig. 1 to 7, have been prepared. The first three show how an orebody may be caved by the use of a system similar to that employed by the Ray Consolidated Copper Company.

In the description that follows only such details are given as seem necessary to make clear the points to be made. A detailed description of the system appears in the Transactions of the American Institute of Mining Engineers, for 1915, by L. A. Blackner.

Fig. 1 shows the plan of a level laid out for the caving of the ore above it. The proper position of the drift, which is driven around the edge of the orebody, was determined by means of drill-holes, as was all other preliminary information necessary for the intelligent application of the system. After, and during the driving of this fringe-drift, cross-cuts were driven completely through the orebody—in this instance 50 ft. apart—and these connect at each end with the fringe-drift. When these cross-cuts, represented by the full lines in

FIG. 3. LONGITUDINAL SECTION OF STOPES.

Fig. 1. have been driven and timbered, stoping will begin. The width of stopes and pillars will, of course, be determined by local conditions. Fig. 2, which is a cross-section through the stopes, represents an extreme case, where the alternating stopes and pillars are each but 10 ft. wide.

The stopes are carried up to within a few feet of the cap-rock by the shrinkage method. To permit this about 35% of the total ore broken in the stope is drawn while stoping is in progress. A raise is put up from each side of the several cross-cuts at an inclination that allows the broken ore to run freely by gravity. Each of these raises, as shown in Fig. 3, will connect upward with one from the next cross-cut. The raises are then connected horizontally and continuously by driving along the ore-body, thus making a stope-back throughout the length of the orebody. Stopping then proceeds upward in the usual

FIG. 1. PLAN.

manner. A thin strip of ore is left overhead, between the broken ore in the stope and the cap-rock, to prevent mixing in case there should be local caving of the ore and cap; also that it may act as a cushion for the cap, and prevent it from breaking into small pieces and thus obviating its becoming too intimately mixed with the ore. After all stopes in a block 200 ft. long have been completed and while they are still filled with broken ore, if it is desired to convert that block into a drawing-section, raises are cut in the pillars similar to the raises made preliminary to stoping. These raises are put in on both sides of each cross-cut, and if deemed necessary they may be connected by auxiliary raises driven from them and meeting over the cross-cuts. When the tops and sides of these raises have been drilled and blasted, the support of the pillar throughout its length will have been removed; the pillar then settles, and rests on broken ore. Later, when the stopes on both sides of a pillar, and the pillar-stope as well, have been drawn, the crushing force of the broken ore in the stopes, together with the weight of the pillar itself and that of the cap-rock above, so fractures the remnant of the pillar that the

ore is readily drawn through the chutes on the level below without further blasting, except possibly an occasional bulldozing shot.

When all of the stopes and pillars, or parts of them, have been drawn up to the cap—that is, all of the ore having been removed from the stopes, including that of the pillars—drifts are driven through the wedge-shaped blocks left standing on the level. These drifts are indicated by the dotted lines in Fig. 1. Chutes to the level below are conveniently placed, at intervals of 100 ft., and chutes for drawing the ore from the pillar are built in every set in the drift. A few holes blasted in the pillar, just over a chute, usually suffice to start the caving. When the stopes have been exhausted, the lagging on the sides of the drifts near the chutes connecting with the next level, may be removed, and the small pillar still standing (see Fig. 7) can be caved directly into the chutes.

The drawing of ore from the stopes and pillars is an important part of the ultimate success of the system. As it is impracticable evenly to draw all of the ore in the stopes and pillars over so large an area at the same time, and in a manner that would allow the cap to settle somewhat uniformly, drawing is begun in three or four drifts at the end most remote from the shaft—a section about 100 ft. long in each of these drifts being opened for drawing. The stopes nearest the 'back fringe-drift' will be drawn on most heavily, and these will be first exhausted. As this condition is approached, new stopes nearer the 'front' fringe will be drawn. This process is continued until all the ore in the stope has been removed. Drawing the ore by this system keeps the cap sloping in two directions, as shown in Fig. 2 and 3, an effort being made to keep the slopes as uniform as possible, without local humps or depressions.

As there is such a small margin of value between ore and waste, constant vigilance is required to prevent drawing the cap-rock filling with the ore. When the ore in a stope has been almost all drawn, small pieces of cap, which have been ground up as the rock settled, will work in and come through the chutes with the ore. These pieces of waste gradually increase in number and size until a point is reached where the mixture cannot be handled at a profit; the stope is then abandoned, and any ore that remains in the stope is lost. This is unavoidable, but usually it is only a small part of the total ore of the block. When drawing from this stope is begun in the next drift, should the ore become jammed above the drift, as frequently happens, the cap over the drift already drawn may work in under the ore. However, when the stope was active, samples were taken every few feet along the back, throughout its length and height, and these, together with the cross-section and height of the stope supplied data necessary to make an estimate of the amount and the grade of ore that should come from it. Should a stope run waste before the estimated amount of ore has been drawn from it, an investigation is made, and while the cause may be discovered, frequently the amount of waste that would have to be

FIG. 4. CROSS-SECTION OF STOPES AND PILLAR READY FOR DRAWING.

handled would be too great to warrant the removal of the contents of the stope to get the ore that remains.

Here then, are two sources of loss, one of them invariably exists, the other occurs occasionally. A far more serious loss may result in the extraction of the pillars. When a pillar is blasted it frequently happens that holes are blown into the stope on either side of the pillar. After the blast a few cars are drawn out to ascertain if the pillar is 'down.' If so, it is left undisturbed until ready to draw. When drawing is begun the pillar-stope is drawn upon more heavily than the stopes on either side of it, the idea being to let the pillar settle and crush itself. At the time of the preliminary, or test drawing, of the pillar, if, after 60 or 70 cars have been removed, the raise is still full of broken ore, it is assumed that the pillar is undercut and settling down.

FIG. 5. CROSS-SECTION OF STOPES AND PILLAR AFTER DRAWING.

When the drawing begins in earnest, ore is taken from the stope-raises and pillar-raise at the same time. The holes connecting the pillar-raise with the stope will permit the broken ore from the stope to be drawn through the pillar-raise. This ore, which is well broken, will run freely and will afford some support for the pillar, which then has not chance to cave. The existence of this condition cannot be determined until the stopes and pillar-chutes run waste, when it will be seen that the tonnage is considerably less than it should be, but it is then too late to apply a remedy, as a large area of cap would have to be removed before the pillar would cave.

Fig. 4 and 5 illustrate a condition of this kind. It is the practice to put the pillar-raises up on a somewhat steeper inclination than that of the stope-raises, so that

FIG. 6. SECTION THROUGH PILLAR-DRIFTS BEFORE DRAWING.

FIG. 7. SECTION THROUGH PILLAR-DRIFTS AFTER DRAWING.

the holes into the stope-raise are at the top of the pillar-raise and at the bottom of the stope-raise.

By reference to Fig. 6 and 7, it will be seen that it is impossible to get the ore from this pillar from the pillar-drifts that are subsequently driven on the level below. When the small pillar on the level has been exhausted the waste from the pillar-stope (underneath the large pillar still standing) will appear in the chutes, and these then will be abandoned.

To obtain the estimated tonnage, and to be sure that no ore is left, drawing may be continued even after the economical point of mixing of the ore and cap has been reached. The amount of rock drawn from the chutes is increased by the presence of the waste, but the metallic content is decreased. If, by means of drill-holes, there had been blocked out a stated number of tons, having a determined metallic content, when a stope has been worked out, if the total calculated tonnage has been extracted, will the average metallic content be as high as was estimated? Would it not be better to leave some of the ore than to try to take it all, including the part mixed with waste? The grade of ore would be the governing factor in answering these questions.

What percentage of the total ore can be extracted free from waste? This is another of the many questions

that have to be answered by one who proposes to mine with the caving-method. There are many forms of caving; in fact, almost every mine, where the system is used, has introduced some original feature. In the Tobin iron mine, at Crystal Falls, Michigan, a system of raises on 16-ft. centres, 'staggered' along the sides of drifts driven on 50-ft. centres, are put up and the tops flared out until they connect. The back left is then drilled and blasted. The entire block above is thus started caving. The weight of the broken cap completes the crushing process, and caving takes place in the form of sloughing.

The ore at the Tobin mine is hematite, which contains from 56% to 60% iron. It occurs between a bed of ferruginous cherty slate and one of carbonaceous slate. The former is called the hanging wall, and grades into ore by the loss of silica. There is no well-defined line between waste and ore and this necessitates much care and vigilance in the extraction of ore by the caving-system.

A description of the caving-system used in various mines, the cost of production; the percentage of ore lost; the saving effected by the use of a timber-mat, and the evolution of the present system at each mine, together with the reasons for the various changes from the original method would make interesting and instructive reading.

Bureau of Standards—Screen-Scale

Uniformity in technical statement facilitates interchange of data and their correct interpretation. Screen-analyses often lack the value that should attach to them, by reason of the diverse standards used. Unless the exact size of screen-opening is known the relation between undersize and oversize is not significant to the metallurgist. The successive sizes of screen-openings must be based upon some exact mathematical relationship in order that the successive over-size quantities may be of service to the operator in solving problems of treatment. Neither does the cumulative curve deduced from the grouping of the successive over-size products furnish a valuable guide unless the ratio of successive screen-openings is dependent on a law which gives a true mathematical curve. None of the proposed standard sets of screens has withstood criticism. As a matter of convenience, and to avoid confusion, mill experimenters have quite generally taken advantage of the Tyler set of screens made especially for this purpose. These are based upon the specifications of von Rittinger, in which the diameters of the successive sizes have a constant ratio of 1.414, that is, the square root of 2, while the areas of the successive openings have a constant ratio of 2. The Bureau of Standards of the Department of Commerce now proposes a standard screen-scale for testing-screens, recommended for common use after having been adopted by a conference of representatives from the American Society for Testing Materials, the American Society of Civil Engineers, the American Institute of Mining Engineers, and other societies. The scale is based on an opening of one millimetre. Sieves in the series with

larger openings than 1 mm. are related to the unit-size by a constant difference in diameter of openings equal to the square root of 2 or 1.4142, while the finer sizes in the series of screens, having openings less than 1 mm. in diameter, differ by a constant equal to the fourth root of 2 or 1.892. Details of the series from an 8-mm. diameter of opening to 0.044-mm., making 25 screens in the set, are shown in the accompanying table.

BUREAU OF STANDARD'S SCREEN-SCALE

The Disposal of Flotation Products

By ROBERT S. LEWIS

INTRODUCTION. A little over two years ago, I was talking with a mill-man from a certain plant where the flotation process had recently been introduced. To my inquiry regarding the success of the flotation equipment, he replied that, at first, it was impossible to obtain a froth. Then suddenly, due to some reason not understood, froth began to form so rapidly that it soon ran over the machines and piled up in great heaps on the mill-floor. It was of such a tough and lasting nature that it would have been an excellent substitute for sole-leather, and it was practically impossible to handle the concentrate because of its stickiness. These statements may contain some exaggeration, but they indicated that a mill-operator's troubles might not cease as soon as a froth was produced. Despite the improvements that have been made in the technique of the flotation process, the satisfactory handling and disposal of flotation concentrate is still a very important problem. In order to secure the latest data on the practice of handling flotation concentrate, a number of letters of inquiry were sent to companies operating mills or smelters. Nearly all the information given below is the result of this investigation.

DEWATERING FLOTATION-CONCENTRATE. This step is necessary as a preliminary to subsequent handling and metallurgical treatment. The large amount of water present in the froth must be reduced greatly before the concentrate can be transported economically, either in sacks or in bulk, to its destination. If shipped a long distance, the freight charge on the moisture contained may reach a considerable figure. The expense for unloading wet and sticky material from cars is much greater than usual. Then, too, custom-smelters often impose a penalty for moisture in excess of a specified figure. It is interesting to note that steamship companies refuse to carry a flotation concentrate that is very wet. Such materials shift so easily that it is impossible to keep the vessel on an even keel. After one ship had been lost, due to shifting of the cargo, steamship companies refused to transport concentrate in which the moisture ran over a stipulated amount.

When the froth is delicate and breaks easily, as does much of the froth from flotation-machines using only air-agitation, a simple treatment on a concentrating-table of the Wilfley type may give satisfactory results. However, it is generally necessary to employ some additional means to insure disintegration of the froth. Centrifugal pumps have been used with success. Bucket-elevators are fairly efficient, but unless included in the original design of a plant, are hardly to be recommended. At the Utah Apex mill, an elevator 71 ft. high is used to assist froth-breaking. Head-room and floor-space may be saved

by using a jet of water instead. Experience has shown that a single large jet, spreading over the full width of the concentrate-launders is to be preferred to a number of smaller jets. In the Daly Judge mill, at Park City, Utah, a patent nozzle, known as the Koerting spray, has been found effective in 'killing' froth. After passing the spray, the concentrate is thickened in Callow cones and is then treated on Wilfley tables to separate the lead from the zinc. The objection to the use of sprays is that the additional dilution of the concentrate means so much more water to be disposed of later. Moreover, where settling-tanks are employed, any appreciable current in the overflow carries out a considerable amount of the finest concentrate. In an endeavor to overcome this objection, Messrs. Cole and Thompson have devised a special nozzle (U. S. patent 1,180,089, Aug. 18, 1916), in which a gaseous liquid, such as compressed air or steam, is mixed with a small amount of water. The resultant jet has a whirling motion. The spray should be directed against the flow of froth and at an angle of from 60 to 90° with the bottom of the concentrate-launders. This retards the progress of the froth and gives the jet more time in which to break it up. The nozzle should be placed at such a distance from the launders as to allow the spray to cover the entire sectional area.

Settling in bins or tanks is a method of dewatering froth that has the merit of simplicity, although it has several disadvantages. Some flotation-concentrate is so fine, all - 200 mesh and with a large percentage of - 300 mesh, that the time required for settling is prohibitively long. Where a large tonnage must be handled the size of the equipment becomes serious. This point is well illustrated in the case of one of the big copper concentrators. An estimate showed that a number of concrete tanks 20 ft. wide, 108 ft. long, and from 5 to 6 ft. deep would be required. The proposed method of operation was to run the froth into a tank until the overflow should become contaminated by the fine concentrate carried over. The tank-feed was then to be cut off and the content settled. The clear water was to be decanted and the concentrate allowed to dry for a day or two. However, the tanks were never built, thickeners and filters being finally adopted. Tanks may have either filter or solid bottoms. In the first case, vacuum-pumps can be used to hasten draining. When solid-bottom tanks are used, the water must be decanted from the settled concentrate, and care must be taken not to allow the escape of the froth, which almost invariably accumulates on the surface of the water. Unless of special design, such as those arranged for a Blaisdell excavator, tanks must be unloaded by shoveling. If desired, the tanks may be provided with steam-pipes to assist drying, but their use

is hardly to be recommended. Spreading the material out in a thin layer on a drying-platform gives quicker and better results, but, in any case, drying by steam-heat is expensive. Classifiers of the Ovoca and Akins type have been used for dewatering concentrate. These are quite successful on coarse or granular material that drains readily.

The following examples illustrate the practice of settling flotation-concentrate in tanks or bins.

1. The Desloge Consolidated Lead Co., Desloge, Missouri, has been drying its lead concentrate to 6 or 7% moisture in steel drying-tanks, heated by steam, and then loading it by hand into unlined box-cars. The method is expensive, and the company will soon install a thickener and filter.

2. Monitor Belmont Mining Co., Belmont, Nevada. From 3 to 4 tons of a silicious silver-bearing concentrate is produced per day. The concentrate is settled, drained, and dried on floors to 5% moisture. It is then sacked and hauled to the railroad, where it is loaded into box-cars. The cost per ton for draining and drying is \$2.20 and \$1.22 for sacking. This method is not satisfactory and the present management is arranging for a totally different method of handling.

3. Name not given. About 45 tons of 60% zinc concentrate, all - 65 mesh, is handled daily. The froth, with a water ratio of 6:1, is run through a 6-in. pipe into bins. Clear water is drawn off between the settled concentrate and the froth. The bins are of concrete, and each holds 20 tons. They are lined with steam-coils. The dried concentrate, containing about 12% moisture, is dropped through doors in the bottom of the bins into wheelbarrows and is loaded into unlined box-cars. The cost is 40c. per ton for drying and 10c. per ton for loading. Coal costs \$2 per ton. The condensation from the pipes is returned to the boilers. A filter will be desirable if a larger tonnage is to be handled.

4. M. W. Atwater, Basin, Montana. About 20 tons of zinc concentrate is produced daily. All of it is - 80 mesh and 70% is - 150 mesh. The froth, with a water ratio of 2:1, is run into one of four bins, each 10 by 10 ft. and 13 ft. high. The overflow, carrying a small proportion of the concentrate, passes into the next bin. When a bin is filled, the upper three feet is discharged into the overflow-bin. The concentrate is then shoveled through the bin-doors directly into box-cars lined with muslin. Two men can load 80 dry tons in 8 hours. The same men prepare the box-cars for loading and attend to the filling of the bins. The concentrate contains from 12 to 13% moisture when loaded, but this drops to 10 or 12% by the time the smelter is reached. As much as 700 tons of concentrate has been handled in the four bins in 30 days. The method is satisfactory, but it is necessary to have deep bins and ample bin-space. Cost of loading is 10c. per ton. The lining of the box-cars costs \$2 each.

5. Atlas Mining & Milling Co., Sneffles, Colorado. The concentrate assays 10% silica, 20% iron, 12% zinc, 17% lead, 60 oz. silver, and 0.2 oz. gold. Fifteen tons is pro-

duced daily. The froth is treated on tables, and the concentrate sent to 50-ton collecting-tanks, the overflow from which is returned to the mill-circuit. From the tanks the concentrate is shoveled into small cars and trammed to an inclined chute 20 in. wide, 18 in. deep, and 90 ft. long, having three steam-pipes along the bottom. The chute discharges into a bin where the concentrate is sacked. It is then hauled to the railroad and shipped in box-cars lined with paper.

6. Mears & Wilfley, Silverton, Colorado. The 10 tons of concentrate made daily is mostly chalcopyrite, and ranges from 80 to 150-mesh. The froth is run into settling-tanks from which two drag-belts, 15 ft. long and 3 ft. wide, requiring $\frac{1}{2}$ hp., pull the concentrate into a bin, from which it is loaded into canvas-lined box-cars by means of wheelbarrows. The concentrate runs 20% moisture when loaded, but only 13% by the time the smelter is reached. The canvas linings are sent back by return-freight. Linings show no wear after six months' use. Cost of handling is about 35c. per ton.

7. Flotation at Mt. Morgan.¹ The ore contains gold, copper pyrite, iron pyrite, and about 70% silica. At the 100-ton testing-plant of this company, the flotation-concentrate was first run into round vats 20 ft. in diameter, 10 ft. deep, and constructed with filter-bottoms. These proved unsatisfactory, as the wet slime kept to the outside and did not drain well. This difficulty was finally overcome by using a number of rectangular tanks, 9 ft. 10 in. by 10 ft. 9 in. and 3 ft. deep, with cocoa matting on a sand-filter bottom. The froth was run through the tanks in series, three or four always being in operation, and each filled with concentrate. The tanks drained to 7 or 8% moisture in 24 hours and the water was perfectly clear.

8. Britannia Mining & Smelting Co.² The concentrate, assaying 14% copper, 26.8% iron, and 20.8% silica, is taken from the flotation-machines by a drag-elevator that delivers it to the shipment-bins, where the moisture is reduced from 20 to 8% by draining. The Tacoma smelter draws the line at 10% moisture. The overflow from the bins goes to tanks, from which the sediment is delivered to the flotation-machines, while the overflow goes to Dorr thickeners. The thickeners give an overflow that goes to waste and a spigot product that is treated in the flotation-machines.

At a mill producing 13 tons of concentrate, assaying 5% lead, 5% copper, 28% iron, 18% silica, with some gold and silver, the froth is settled and dried in wooden tanks having steam-coils on the bottom. The concentrate is then shoveled into box-cars that have been lined with paper. Cost is about 18c. for drying, and 23c. for loading, or a total of 41c. per ton. The tanks do not give sufficient settling-area, and the costs are considered high.

At another plant, both a zinc and a lead concentrate are made. The total of concentrates produced is from 3 to 4 tons. The concentrate is settled in shallow tanks, 16 in. and 30 in. deep, the water being decanted. Steam is

¹W. Shellshear, Aust. Inst. M. E., June, 1916.

²T. A. Rickard, M. & S. P., November 11, 1916.

then turned into pipes on the floor of the tanks. When the moisture is reduced to 11%, the concentrate is shoveled into box-cars lined with resin-sized building paper. The tanks are housed over. Some are provided with fan-induced draft for drawing off the water-vapor and the rest have natural draft. The former are the more satisfactory. The cost of loading is 21c. per ton.

A plant making 24 tons of lead concentrate per day uses a Dorr thickener to remove most of the water from the froth. The concentrate is then dried to the desired

and filter will soon be installed. Even though it could be done easily, it would not be desirable to dry the concentrate to the point of dusting.

It is said that at the Miami mill, the concentrate from both the flotation-machines and the tables is run into round steel tanks having filter-bottoms, and with a central opening in the tank-bottom. A vacuum-pump accelerates the draining. When drained, a plug is removed and the concentrate is shoveled onto a belt-conveyor passing beneath the tanks. This conveyor discharges

FIG. 1. AGITATORS FOR 12 BY 10 FT. TANKS, 50-TON ZINC PLANT MAGMA COPPER CO.

point in tanks 16 in. deep with steam-pipes along the bottom and the sides. Steam-pressure is 75 lb. per sq. in. The concentrate is loaded into unlined box-cars. Cost of treating is \$1.15 per ton. The method is not satisfactory, and a filter will soon be installed. This use of steam for reducing the moisture-content of flotation-concentrate is expensive.

In the case of a plant producing 10 tons of concentrate per day, part of which is a 50% zinc product and the rest a 65% lead product, this material is settled in flat-bottom tanks, the water is then decanted, and the concentrate shoveled onto draining-platforms, from which it is loaded into box-cars lined with felt. The zinc concentrate contains 20% moisture, and the lead concentrate 15% moisture. Cost of treatment is about 20c. per ton. This method is only a temporary expedient; thickeners

onto another or cross-conveyor that loads directly into box-cars.

The most common method of dewatering flotation concentrate is by the use of thickeners and filters. Though this makes an expensive equipment, it gives a rapid and a fairly positive control over the moisture-content of the finished product. There is some accumulation of froth at the top of the thickeners. This is difficult to handle and contaminates the overflow from the tanks. Unique testimony to the apparent solidity of this accumulation is found at one mill where 'near-tragedies' are occasionally enacted because usual canine perspicacity fails to deter inquisitive dogs from attempting to take short cuts across the thickeners. Sprays are sometimes used in an attempt to break up this froth and baffle-boards may be employed, either around the edge of the tanks to protect the over-

flow, or at the centre and extending below the surface of the water in the tank. In the latter case, the incoming froth discharges into the space within the boards, and is broken up in passing out into the rest of the tank. The Consolidated Arizona Copper Co., at Humboldt, Arizona, has found it profitable to send all the flotation-tailing to thickeners, skim off the froth, and add it to the regular output.

The filters used are generally of the vacuum type, such as the Oliver and Portland, although the Kelly press, a pressure type, has been installed in some mills. The pressure-filter has the advantage that it can reduce the moisture in the concentrate to a very low figure, but it has been considered intermittent in action, costly to operate, and requires close attendance. However, a company that produces a large daily tonnage of concentrate has recently decided to install Kelly filters. These presses, of improved design, were adopted after a competitive test with a filter of the vacuum type. The vacuum-filter has no competitor when treating a concentrate that makes a thick cake and filters easily, but, when the concentrate is exceedingly fine and retains water tenaciously, the capacity of the filter becomes so reduced and the percentage of moisture left in the cake is so high that a filter of the Kelly type is to be preferred. A slight increase in total cost of operation (cost for labor is little, if any, greater than for the vacuum filter) is more than off-set by the reduced moisture in the product. The positive action of the Kelly press enables it to handle material that cannot be satisfactorily treated on a filter of the vacuum type.

In order to give sufficient capacity together with a low proportion of moisture in the cake, the vacuum-filter must have a feed that is at least 50% solid. At one mill the moisture in the material going to the filter must be held at the low figure of 35% in order to get satisfactory results. Heating the pulp in the filter-tank to about 100° F. or adding slaked lime will often increase the capacity of the filter. At the Inspiration mill Dr. Gahl has plotted the percentage of silica in the concentrate along with the moisture content of the filter-cake. A change in the former due to variations in the ore, or in the operation of the plant, is followed by a closely corresponding change in the latter. This suggests that the percentage of silica present has a marked effect on the dewatering action of the filter. It would be interesting to know whether this holds true in other plants and with different kinds of concentrate.

In a recent bulletin of the American Institute of Mining Engineers, J. M. Callow discusses the continuous thickening of feed for vacuum-filters. He states: "Our experience has not been satisfactory with the continuous plan, and it is for this reason that in all our recent plants, we have been installing the intermittent system. Until shown to the contrary, we think that this offers the best solution, in that with it you have complete control of the necessary density for the filters, there is no danger from losses in the overflow, and the froth which accumulates during the filling of the tank is completely disposed

of at each cycle of the operation, and, therefore, cannot accumulate. The agitator for stirring the contents of the tank during the discharge period is copied from those used at the Goldfield Consolidated mill. It consists of arms secured to a square revolving shaft, suspended by a chain-block, and passing through a square hole in the driving-gear. It is simple, inexpensive, and gives no trouble whatever. It is illustrated in the accompanying figure. The thickened pulp may be drawn off from a central-bottom discharge. More recent practice is to draw off through a valve or molasses gate on the side of the tank, or better still, with a diaphragm-pump." Fig. 1 shows an installation for a 60-ton zinc plant.

The following examples illustrate the practice of filtering flotation concentrate.

1. Montezuma Mines & Milling Co., Montezuma, Colorado. This plant is producing daily 10 tons of concentrate that assays 42% zinc and 9% iron. The froth is sent to tables and the table-concentrate is filtered. The cake contains only 3% moisture.

2. Portland Gold Mining Co., Victor, Colorado. From 13 to 15 tons of concentrate, assaying 55 to 70% silica and 2 oz. gold, is made daily. The froth goes to Dorr thickeners and Portland filters. The moisture in the filter-cake is 30%. The concentrate is loaded by hand into tight-bottom box-cars. Cost of dewatering and loading is 50c. per ton. The results are not considered satisfactory.

3. Name omitted. Daily production is 10 tons of concentrate, assaying 40% zinc, 7% silica, 14% iron, 30% sulphur, 7% lead, with a little gold, silver, and copper. This is dewatered in Portland filters to 14% moisture, and loaded by hand into unlined box-cars. The cost for dewatering and loading is 15c. per ton.

4. St. Joseph Lead Co., Bonne Terre, Missouri. Forty tons of concentrate is handled per day. The analysis is 50% lead, 2% zinc, 9% lime, 4% iron and 6% insoluble. The froth, containing 90% moisture, goes to a 38 by 6 ft. Dorr thickener, which gives a spigot-product of 35% moisture. This pulp is sent to one 11 ft. 6 in. by 12 ft. Oliver filter, and the cake, containing 14% moisture, is loaded into gondola cars by means of a rubber-belt conveyor. A Root vacuum-pump, requiring 29½ hp. is used for the filter. The operation of the filter itself required 1½ hp. Cost for dewatering is 26c., for loading 2c. and for maintenance 6c., making a total of 34c. per ton.

5. Engels Copper Mining Co., Taylorsville, California. Between 30 and 40 tons of concentrate is produced in 16 hours. The assay is 35% copper and 30% insoluble. The froth is elevated to two settling-tanks having cone-shaped bottoms. The thickened concentrate then goes to an 8 by 8-ft. Oliver filter, which gives a cake containing 12% moisture. Steam is used to heat the pulp in the filter-tank. The filter-product is sacked and carried 1½ miles by a tram to auto-trucks, which, in turn, carry the concentrate to the railroad 30 miles away. The cost for dewatering and filtering is \$1.50 per ton.

6. Bunker Hill & Sullivan Co., Kellogg, Idaho. An-

alysis of concentrate is 45.9% lead, 6.6% zinc, 13.2% sulphur, 10.4% insoluble, 9.8% iron, 26.6 oz. silver with a little copper and manganese. Twenty tons is produced per day, all of it - 200 mesh. A 40 by 12-ft. Dorr thickener and a 6 by 8-ft. Oliver filter are used for dewatering. The filtered concentrate contains 11% moisture. It is loaded into box-cars. The cost is 7c. for dewatering and 15c. for loading, making a total of 22c. per dry ton. It is essential that the feed to the filter be as thick as possible, about 35% moisture being a satisfactory figure. It has been found that wiping the oily film that forms on the filter-cake, with a rawhide beater, reduces the moisture nearly one-half.

7. Detroit Copper Mining Co., Morenci, Arizona. All flotation concentrate goes to one Dorr thickener. A 6 by 8-ft. Oliver filter takes as much of the thickened product as it can handle, together with the froth from the top of the thickener, which is removed by paddle-wheels. The slime-overflow from the thickener is sent to a settling-tank, and the spigot-product is shipped as flotation slime. An analysis of a composite sample of the filter-product and slime is 20.32% copper, 22.3% silica, 13.2% iron, 12.6% alumina, 1.4% lime, 1% magnesia, and 19.8% sulphur. The moisture in the filtered concentrate is 34.6%, and the slime carries 80.6% moisture, which necessitates its being shipped in tank-cars. The equipment is inadequate, and a larger plant is required to give satisfactory results.

8. Consolidated Nevada-Utah Corporation, Pioche, Nevada. About half of the total tonnage, 18 tons of concentrate per day, is thickened and filtered. It assays 42% zinc, 10% iron, 1% lead, and 11% insoluble. The flotation concentrate is very slimy and is mixed with the fine concentrate from the tables in order to obtain a product that can be filtered satisfactorily. The coarse concentrate from the roughing-tables is not filtered. Three 16-ft. agitators are used for thickening. One is running and one is filling while the third is being decanted. Each requires 5 hp. The 4 by 8-ft. Portland filter reduces the moisture to between 9 and 10% and consumes 1 hp. for operation. The concentrate is shipped in box-cars with a 12-in. board nailed across the door.

9. Old Dominion Copper Mining & Smelting Co., Globe, Arizona. Of the 36 dry tons of concentrate handled per day, fully 91% is -200 mesh. An analysis gives 18% copper, 24% iron, 27% sulphur, and 22% insoluble. The froth, containing 8% solid, is pumped by a 3-in. centrifugal pump to a 10 by 28-ft. Dorr thickener, which gives a spigot-product of about 57% solid. This goes to an 8 by 11.5-ft. Oliver filter. The filter-cake contains 19% moisture. The filter discharges into a bin from which the concentrate is loaded into cars by means of wheelbarrows. The power consumption of thickener and filter is 1.24 kw. per hour. The filter operates at a 21-in. vacuum and 18 lb. for blowing-pressure. Cost is 1.6c. for dewatering and filter-power, 8c. for repairs to filter and renewal of canvas, and 21c. for loading concentrate, making a total of 30.6c. per ton. The com-

paratively high cost of loading is due to the necessity of loading into box-cars, which makes it impossible to use a belt-conveyor. Trouble is experienced from the accumulation of froth in the thickener. This robs the thickener of settling and thickening capacity. Sprays of water break up some of the froth but do not prevent a gradual accumulation.

10. Utah Leasing Co., Newhouse, Utah. The froth goes to a 22 by 10-ft. Dorr thickener and then to an 8 by 6-ft. Oliver filter, which gives a product containing 20 to 21% moisture. Great difficulty is experienced in settling and filtering the fine slime. Sodium silicate, soda-ash, and lime have been tried, but without marked results. Allowing 24 hours or more, of undisturbed settling in tanks seemed to be of little avail. Fifteen tons of concentrate is produced daily. It assays 15 to 16% copper, 33 to 36% silica, and 20 to 22% iron.

11. Gold Hunter Mining & Smelting Co., Mullan, Idaho. A screen analysis of the 30 tons of concentrate produced per day shows the following results: + 100 mesh, 0.2%; + 150 mesh, 1.8%; + 200 mesh, 6.4%; and - 200 mesh, 91.6%. It is a lead concentrate with about 16% silica. The froth is thickened to more than 50% solid in a 30 by 5-ft. Dorr thickener. Froth, running 60% solid, is mechanically skimmed at the top of the tank and unites with the spigot-product, going to an 8 by 6-ft. Oliver filter. A vacuum of from 24 to 25 in. is maintained by a wet-vacuum pump. A receiver with a barometric leg is used for the filtrate, which is clean but is run to settling-tanks. Oakdale No. 3 twill is used for the filter-cover. It lasts six months. The agitator is run at 30 r.p.m., but the air-lifts are not used. The emergency air-agitators are used once daily. The canvas is blown from one to three times per day with compressed air under 20 lb. pressure. Occasionally the canvas is steamed, using a 1-in. pipe perforated every inch with $\frac{1}{8}$ -in. holes. Steam-pressure is 60 lb. per square inch. A scraper is mounted on a flat rigid casting that holds it just off the wires. The dried product drops into a bin, from which it is loaded into unlined box-cars by means of wheelbarrows. The concentrate contains 10% moisture. The overflow from the thickener is generally clean, but, at times, a little froth escapes. The overflow goes to settling-tanks and ponds. The cost is 4 $\frac{1}{2}$ c. for dewatering, of which 3 $\frac{1}{2}$ c. is for power and the rest is for repairs and labor. Loading cost 14c. per ton, being based on a wage of \$4.50 for 8 hours. The filtered concentrate takes up more space and this adds to the cost, as it has to be shoveled back into cars.

12. Anaconda Copper Mining Co., Anaconda, Montana. From 1800 to 1900 tons of wet concentrate is produced per day. This is about 148 tons per filter-day. The screen analysis shows: + 48 mesh, 0.19%; - 48 and + 200 mesh, 29.7%; - 200 and + 300 mesh, 11.91%; - 300 mesh, 57.18%. The chemical analysis shows 9% copper, 28% silica, 25% iron oxide, 10% alumina, and 27% sulphur. Twenty-one 50 by 12-ft. Dorr thickeners are used. The thickeners for the slime-concentrate require 15 minutes for a revolution and consume 0.6 hp.

each. Those for the sand-concentrate revolve once in 9 minutes and consume 1.5 hp. each. The thirteen 11½ by 12-ft. Oliver filters require 1 hp. each for operation, 25 hp. each for wet vacuum, and 15 hp. each for dry vacuum. The filter-feed is thickened to 50% solid and the cake runs 15% moisture. The pulp is heated to 100° F. in the filter-tank. The filtered concentrate is taken directly to the roasters on an 18-in. belt-conveyor, which requires 25 hp. for its operation. The method is satisfactory. The belt-conveyor handles the material without difficulty. The froth, containing from 18 to 20% solid, is delivered to a baffle-box at the centre of each Dorr thickener. The box is about 5 ft. square and extends down to within a few inches of the rakes. Surrounding this is another baffle about 15 ft. square and extending about 18 in. below the surface of the water. The baffles catch a large part of the froth, which is there broken up by a spray of water. The overflow, containing a small amount of fine material that will not settle, is run to a slime-pond.

13. Calaveras Copper Co., Copperopolis, California.³ The concentrate contains 14.4% copper, 29.5% iron, and 14.9% insoluble. When the remodeling of the plant is completed about 50 tons of concentrate will be produced daily. At present the output is 25 to 28 tons. The froth is thickened to 60% solid in a 22 by 10-ft. Dorr thickener and the moisture is reduced to 13% by means of an 8-ft. Oliver filter. In the new plant, it is planned to convey the thickened product to the filters through a 5-in. pipe, which will contain a 1-in. steam-pipe. This will heat the pulp without diluting it with the condensed steam.

14. Braden Copper Co., Chile. Both the table and flotation concentrate are run into concrete settling-tanks at the bottom of the mill. There are eight tanks in all, and four are used together alternately. The settled table and coarse flotation concentrate is loaded by a grab-bucket into cars. The tank-overflow, having a water-ratio of 10 or 20:1, goes to Dorr thickeners and the thickened product (water ratio of 1:1), is sent to two Kelly and four Oliver filters, only four of which are in operation at the same time. About 50 tons of solid per day is recovered in this manner. The fineness of the material, 98% of which is -200 mesh, results in low filter-capacity. At this plant supplies constitute 60.4% of the total direct milling-cost. Concentrate-handling makes up 8.33% of the total labor and 1.14% of the total supplies. Filtering concentrate makes up 5.46% of the total labor and 2.61% of the total supplies. About 50 tons is handled per day, of which 98% is -200 mesh.

15. Inspiration Consolidated Copper Co., Miami, Arizona. Five 60-ft. and three 80-ft. Dorr thickeners are used for handling 651 dry tons per day of mixed table and flotation concentrate. The latter amounts to 75% of total concentrate by weight and carries 90% of the copper. This gives 44.8 sq. ft. settling-area per ton of concentrate. The thickened product, having a water ratio of 1.65:1, passes through tunnels to two bucket-

elevators, which deliver it to six 11 ft. 6 in. by 12-ft. Oliver filters. The filter-cake contains approximately 17% moisture. In attempting to reduce the moisture in the cake, the pulp in the filter-tanks was heated by steam. This increased the capacity of the filters, but did not affect the moisture in the cake. Adding slaked lime gave the same result. Lime is now used to increase the capacity of the filters. A double ring of high boards is used to prevent the contamination of the thickener-overflow by the froth accumulated on top. A record was kept of the portion of silica in the concentrate and the moisture in the filter-cake. The results are shown in the accompanying chart, Fig. 2 (Sept. 1916 Bull., A. I. M. E.), and would seem to indicate that the amount of moisture remaining in the cake depends upon the silica present in the concentrate. An 18-in. belt-conveyor running at a speed of 150 ft. per min., carries the concentrate to a steel loading-bin, directly above the railroad track. At the head pulley a rubber scraper is used to assist in removing the concentrate from the belt-conveyor. The bin is round with a cone-shaped bottom. Some difficulty is experienced in discharging the material from the bin. The total power consumption for thickening, elevating, filtering, and conveying is 5.1 kw.-hr. per ton of concentrate. The cost for dewatering and loading is between 20 and 25c. per ton.

A certain plant, producing 15 tons of a 12% copper concentrate per day uses a Dorr thickener and a 4 by 8-ft. Oliver filter. The cake is shoveled into wagons. Cost for dewatering and loading is given as 50c. per ton. Another plant, making 35 tons of zinc-lead concentrate per day, delivers the froth to a bucket-elevator in order to break it up. It then goes, without dewatering, to an Oliver filter, which gives a cake containing 10% moisture. This is loaded into gondola cars lined with canvas. The cost is 10c. per ton.

A copper company, which produces from 15 to 18 tons of concentrate per day, assaying from 14 to 18% copper and 28 to 34% silica, thickens the froth in Callow cones and then sends it to an Oliver filter. The filter-cake drops down a chute lined with 1.5-in. steam-pipes into a bin, which is also lined with steam-pipes. The concentrate is then shoveled from the bin, and shipped in gondola cars patched with sacks and thin boards. In spite of the filtering and drying, the shipping-concentrate runs from 14 to 18% moisture. It is so wet and sticky that it requires a great deal of shoveling. Cost of loading is from 22 to 25c. per ton. The dewatering and drying cost is not known.

SMELTING FLOTATION CONCENTRATE. The concentrate generally comes to smelters so well established in methods of operation that their work is of a routine nature. If this material is put through the regular smelting process, it has been found that the physical condition of the concentrate is such as to require certain modifications in the usual methods of operation.

The actual smelting of a flotation product is quite similar to the smelting of any other concentrate. The objections to it are of a physical rather than of a chem-

³H. R. Robbins, M. & S. P., November 25, 1916.

ical nature, but they are enough to cause many smelters to impose a penalty of \$1 per ton. If the concentrate arrives at the smelter in a wet and sticky condition, it is difficult and expensive to unload. A large moisture-content means extra fuel-consumption in driers and roasters, and in furnaces, when charged directly into them. The great fineness of the material causes a heavy loss from dusting. This is especially true where it is necessary to smelt in blast-furnaces. Briquetting should reduce this loss, but it is often difficult to produce satisfactory briquettes. Unless it can be mixed with

FIG. 2. CHART SHOWING SILICA IN CONCENTRATE AND MOISTURE IN FILTER-CAKE.

a large proportion of coarse material, flotation concentrate is hard to sinter. It chokes the grates, interferes with the draft, and reduces the capacity of the sintering machines. In some cases it may be necessary to pre-heat before a successful sinter can be produced. During the roasting process, there is often a marked tendency toward agglomeration or 'balling up,' and lumps are formed that roast on the outside only. Fig. 3 shows two lumps (natural size) of zinc concentrate that passed through the roaster, but came out with unaltered cores. Often troublesome accretions are formed in the roasters. At one plant it was found that a preliminary drying of the concentrate before roasting prevented 'balling.' However, drying usually makes the material lumpy and hard to feed. Where a large amount of flotation concentrate is roasted, special apron-feeders must be provided to handle this material.

The roasted product is of such a light and fluffy nature that it must be handled with great care to keep down the loss from dusting. At one plant, the cars are loaded in a tunnel connected to a dust-chamber and stack. Should a sufficiently large amount of dust be produced, it would pay to add a Cottrell tube-system. At another copper smelter, the side walls of the reverberatory furnaces have slots cut through them just above the slag-line. Inclined iron plates are fastened to the outside of the walls so that the charge can be shoveled onto them and work slowly down into the furnace as the smelting proceeds. This method of gently presenting the charge to the heat at a point where the draft is weakest causes a minimum formation of dust. It is far less than if centre-charging is used.

The foregoing discussion concerns lead and copper smelting, but zinc smelters, as well, have their troubles when treating flotation concentrate. At one plant, the unloading from cars is done by shoveling or by a grab-bucket. The material is then dried in a rotary drier and roasted in muffle-kilns. Because of its fineness, it is considered more difficult to treat than other zinc concentrate. At a second plant, all the unloading is done by shoveling, but it is considered an unsatisfactory method. At a third plant, shoveling is considered expensive, though it is acceptable in other regards. The concentrate is roasted in open-hearth furnaces fired with natural gas. Very little trouble is experienced in roasting. No difficulty is found in smelting, but the dust-loss is higher than for coarser material. At a fourth plant, flotation concentrate makes trouble all through the smelting process. Unloading is done by shoveling into wheelbarrows. The material is frozen in winter and is hard to handle. It is roasted in reverberatory furnaces to 1% sulphur or less (cost of roasting is about \$1.70 per ton). The coarse concentrate is first dried to about 4% moisture, but the fine concentrate is not dried. The difficulties found in roasting are high dust-loss, the forming of accretions in the roasters, and the fusing of the fine concentrate. Smelting is done in the usual gas-fired distillation-furnaces. The fine material is more sub-

FIG. 3. LUMPS OF INCOMPLETELY ROASTED ZINC CONCENTRATE SHOWING UNALTERED CORES OF SULPHIDE.

ject to loss through overheating. It slags more easily with consequent loss of retorts. The charge is more likely to cake in the charge-cars, if too wet, and to blow out of the retorts, if too dry. The very fine flotation concentrate is difficult to roast and smelt.

One smelter superintendent forcibly summarizes the situation in the following brief sentence. "Flotation concentrate is considered a damned nuisance."

Examples of smelting practice are given below.

1. Consolidated Mining & Smelting Co. of Canada, Trail, B. C. The amount of flotation concentrate smelted is too small to afford reliable data. It is charged directly into blast-furnaces, so that the dust-loss probably is serious. A briquetting plant is being installed.

2. Omaha Plant, American Smelting & Refining Co., Nebraska. The copper concentrate, used incidentally to supply sulphur to the charge, is briquetted with 7% lime, and, after drying for 72 hours, is charged into the

blast-furnaces. This material, even after briquetting, produces considerable flue-dust.

3. U. S. Smelting Co., Midvale, Utah. The concentrate is shoveled from the cars and is briquetted with flue or bag-house dust, heavy with lime that had been introduced for the purpose of neutralization. The cost is about \$1. per ton. The sintering in Dwight-Lloyd machines is not good, due to a poor mixing. The product is smelted in lead blast-furnaces. Flotation concentrate is considered a great nuisance.

4. Garfield Smelting Co., Garfield, Utah. The flotation concentrate is mixed with table and vanner products. It is then bedded with fluxing ores and later fed to McDougall and Herreshoff roasters. While the quantity of flotation concentrate treated is too small to cause any serious difficulty or to require special treatment, close observation shows that it has a tendency to form lumps that do not break up easily in the roasters. In fact, some lumps roast only on the outside. A large increase in the amount of flotation concentrate handled would probably necessitate a special feeding device.

5. Selby Smelting Co., California. The flotation concentrate is unloaded by shoveling and is spread out to dry. Cost for spreading is about 30c. per ton. It is then sintered and smelted in lead blast-furnaces. No trouble is experienced, other than the production of a large amount of flue-dust.

6. Anaconda Copper Mining Co., Montana. About 20% of fine table and jig concentrate is mixed with the flotation product. This is delivered to Wedge roasters by belt-conveyors. Each furnace-bin holds 25 tons. A large steel apron-feeder is used for supplying the material to the furnace. The roasted product is extremely fine and difficult to handle. It is loaded into covered cars in a tunnel that is entirely closed except for a stack at one end, which produces a slight draft. The amount of dust issuing from the stack is small. If sufficiently valuable, the dust could be recovered by a Cottrell precipitator. The smelting in coal-fired reverberatory furnaces presents no difficulties.

7. Murray Plant, American Smelting & Refining Co., Utah. The flotation concentrate arriving at this plant is wet and sticky, and bad to handle. It is mixed with sulphide ores and roasted or sintered and then smelted in lead blast-furnaces. It is considered to have an adverse effect on the smelting process. It chokes the roasters and tends to give a poorly-roasted product. The dust-loss is heavy. The fine powdery product is objectionable from a lead-smelting standpoint.

8. Ohio & Colorado Smelting & Refining Co. All flotation concentrate is either pre-roasted and sintered or sintered directly. The pre-roasting is done, after mixing with coarser material, in Godfrey and Wedge furnaces. The flue-dust and mechanical dust-loss is increased. Dwight-Lloyd machines are used for sintering. Even though coarser material is added, the capacity of the sintering-machines is decreased.

9. Bartlesville Zinc Co., Bartlesville, Oklahoma. The zinc concentrate from filter-presses is unloaded by shov-

eling. It must be dried in a machine of special design to avoid excessive dust-loss. It is then roasted in ordinary kilns. Allowance for excessive dust losses met with at every step in its treatment should be provided for when purchasing flotation concentrate.

10. Braden Copper Co., Chile.⁴ The first flotation concentrate produced at the plant was so wet that it could not be briquetted, and so fine that it was hard to filter and dry. When charged directly into the blast-furnaces, the amount of coke required was increased from 12 to 16%. The drained concentrate from the bins contained 50% moisture and the filtered concentrate ran 30% moisture. After much experimenting, it was found that nodulizing in rotating kilns gave a product that was a first-class smelting material.

11. International Smelting Co., Miami, Arizona. The concentrate is unloaded from steel cars, having removable bottoms, onto belt-conveyors that deliver it to bed-ding-bins, where the necessary fluxes are added. The beds contain about 4000 tons, 80% of which is flotation concentrate, and are made in V-shaped steel bins that have removable-slat bottoms. Beginning at one end, the mixture is fed from an approximately vertical face onto a belt-conveyor, which discharges into Wedge roasters, used as driers only. The material is sticky and hard to handle. It is dried to about 14% moisture, and is then fed to oil-fired reverberatory furnaces. The difficulties in smelting are practically of a mechanical nature, due to the handling of this extremely fine charge, 50% of which is -200 mesh. The plant was designed for smelting flotation concentrate, and every precaution was taken to avoid dust-losses.

12. At Mt. Morgan, Queensland, Australia,⁵ an ore containing about 2% copper and from \$5 to \$7 in gold is treated by flotation. Nearly 70% of the gold is free. It was found that by grinding the ore very fine, much of the gold was caught in the thick froth of the flotation-machine. The ore was ground to 80-mesh. There was no increase in the saving of copper, but the extra gold recovered paid for the cost of grinding. As long as only a small tonnage was treated, the concentrate was mixed with blast-furnace flue-dust, in the proportion of 1:3, and sintered in a Dwight-Lloyd machine with excellent results. But when the percentage of concentrate was increased, the sulphur content rose to such a figure that the machine did not give a good product, and its capacity was reduced, owing to the choking of the bed by fine concentrate. Pre-roasting followed by pot-roasting was then tried. An Edwards furnace was first used, but the roasted product was so fine that it could not be handled in the Dwight-Lloyd machine or in the pots. Tests made by pre-roasting in a Godfrey furnace and sintering in pots proved satisfactory, and such a plant was installed. It was found that the product from the Godfrey furnace was coarser than the concentrate, some agglomeration

evidently taking place. A sketch of one of the sintering-pots is shown in the accompanying figure.

13. Tacoma Smelting Co., Tacoma, Washington. The flotation-concentrate arriving at this plant is unloaded from ships in tubs that are filled by hand-shoveling. Owing to the sticky character of the material, this work is disagreeable and costly. Roasting is done in Herreshoff furnaces, the upper floors of which are used for drying only. It is necessary to clean the roasters frequently. Reverberatory furnaces are used for smelting. Elaborate machinery must be used in order to keep dust-losses from becoming excessive.

14. Helena (Montana) plant of A. S. & R. Co. Unless

fineness, smelters must necessarily suffer considerable loss from dusting when handling flotation-concentrate. This loss is undoubtedly higher than in the case of ordinary ores or coarse concentrate; therefore it justifies a higher charge for treatment.

SUMMARY. The various methods of handling froth may be classified as follows:

1. Breaking by means of centrifugal pumps, bucket-elevators, jets, or on tables.
2. Dewatering in tanks, with or without filter-bottoms. Steam may be used to assist drying.
3. Dewatering in classifiers of the Ovoca and Akins type.

FIG. 4. SINTERING-POT USED AT MOUNT MORGAN.

filtering or drying has been done at the mill, the flotation-concentrate sent to this plant carries from 20 to 25% moisture. In summer this material has the consistence of liquid mud, and could almost be unloaded from cars by means of a pump. In practice, men wearing high rubber boots shovel the concentrate from the cars into bins. The cars can be washed out, but the material sticks to the sides of the bins, dries, and causes loss from dusting. In winter the concentrate will freeze solid in the car, and has to be thawed or else mined with gads and picks. The cost of unloading is then excessive. No particular difficulty is presented when the concentrate has been dried or filtered before shipping. The lead concentrate is first sintered in Dwight-Lloyd machines. From 10 to 15% of flotation-concentrate is mixed with miscellaneous sulphide ores, including a small quantity of matte and from 5 to 10% of crushed limestone. With this mixture a fairly good sinter can be obtained. This material is then transferred to H. & H. pots, where it is converted into a slagged and fairly porous product containing less than 2% sulphur. Smelting in lead blast-furnaces presents no difficulties. Owing to its extreme

4. Continuous thickening, followed by filtering.

5. Intermittent thickening, followed by filtering.

The use of tanks for dewatering concentrate necessitates unloading by shoveling, unless the tonnage to be handled is sufficiently great to warrant the installation of a crane and grab-bucket. The cost of loading varies from 10c. per ton, where the concentrate can be shoveled directly into cars, to 25c. and more per ton, when wheelbarrows must be used. In case gondola cars are to be loaded, a belt-conveyor will reduce the cost to 2 or 3c. per ton. The employment of steam for drying can hardly be recommended, especially where pipes are placed in tanks. The concentrate should be spread out in a thin layer on a uniformly heated surface. In a tank the concentrate in contact with the steam-pipes is quickly dried, but the moisture is driven out only to condense in the main body of the concentrate, which dries very slowly. Such a method of dewatering is necessarily expensive. Filter-bottoms for tanks may be advisable where the concentrate drains fairly well, and, in such instances, the trouble from accumulated froth is eliminated. Where the water must be decanted from settled concentrate, the

decanting apparatus should be so designed that it can work in the clear water between the unbroken floating froth and the top of the settled concentrate.

Continuous thickening, followed by filtering is a method commonly employed, but the troubles arising from the accumulation of floating froth in the thickener and the difficulty, at times experienced, in getting a spigot product low enough in moisture for satisfactory filtering should be considered when making such an installation. One large company gives the cost of thickening in Dorr thickeners, dewatering on a continuous filter and loading by gravity at 65c. per ton. Another company states that thickening and filtering (continuous type) costs 10c. per ton. Intermittent thickening, followed by filtering, seems to offer the most positive control over the moisture in flotation concentrate. Filters of the pressure type will give good results on material that cannot be satisfactorily treated on vacuum-filters.

A preliminary treatment, before smelting, is nearly always given flotation concentrate. Such treatment would come under one of the following heads, although two or more may be combined:

1. Drying.
2. Briquetting.
3. Nodulizing.
4. Sintering.
5. Roasting.

The difficulties in the smelting of flotation concentrate are caused by the extreme fineness of this material. Briquetting should be a good method of preparing the concentrate for direct smelting in blast-furnaces, but it is not easy to make a strong briquette that will not break up and produce much flue-dust before it is smelted. Nodulizing gives an excellent smelting product, besides driving off some sulphur, but the loss in dust may be considerable. Roasting presents such troubles as the necessity of specially designed feeders for furnaces, the formation of accretions, and the non-roasting of the interior of lumps, heavy dust-losses, and the production of a light fluffy product that is not easy to handle. The cake from sintering or pre-roasting and sintering is quite suitable for feeding to blast-furnaces, but it is necessary to mix coarse material with the flotation concentrate in order to get a well-sintered product and to prevent too great a falling off in the capacity of the machines.

At the present time flotation concentrate, being a new and unusual material, is difficult to handle. Unless specially designed for the purpose, smelters cannot be expected to treat this product in the smooth manner of their regular work. However, metallurgists are keenly interested in solving the problems thus presented, and, as the tonnage of ores that are being concentrated by the flotation process increases, plants smelting only such concentrate will soon experience no serious hindrance to satisfactory operation.

SILVER has been selling during the last three months at prices not recorded since 1893.

Raw Material for Sodium Cyanide Manufacture

*The presence of cyanogen in coal-gas, or in the gases from a by-product coke-oven, is attributed to the breaking down of ammonia in contact with the hot coke or the highly heated walls of the retort. Although the amount of cyanogen obtainable depends on the quantity of nitrogen in the coal, there is a direct relation to the temperature of the coke and the walls of the coking-chamber, the higher temperatures favoring combination with the carbon to produce hydrocyanic acid, thus:

The original nitrogen content of the coal ranges from 1 to 2%. The removal of the cyanogen from the gases is possible only in the presence of ammonia, hence the extraction is accomplished previous to passing the gas through the ammonia-washers, but not until after the naphthalin has been absorbed by anthracene-oil, creosote-oil, or water-gas tar. The cyanide washer is an apparatus in which fresh iron sulphate enters at one end, meeting a current of the oven-gases. The H_2S in the gas first precipitates mono-sulphide of iron, which in turn reacts with the cyanogen and ammonia, forming ferro-cyanide of ammonia. The sludge liquors are treated in a still and neutralized with sulphuric acid. They then contain insoluble double ferro-cyanide of ammonia and iron, along with ammonium sulphate, ferrous sulphate, and free acid. This is filter-pressed, and the press-cake, or 'blue,' as it is called in the trade, is sold on the basis of its equivalent in potassium ferro-cyanide,

and from this crude product is manufactured the sodium cyanide used in the metallurgy of gold.

POCKETS OF GOLD are not confined to any particular kind of rock. They have been found in limestone, in granite, in slate, in diabase, in andesite, in tuff, in quartz veins, in seams where there was apparently no vein at all. It is rather the existence of peculiar structural conditions that influences the deposition of gold in those masses called pockets, rather than the kind of rock. No two pocket-mines are exactly alike, nor do any two pockets occur under identical conditions. In the pocket-mines of California the gold is usually found at the intersection of two or more planes—veins, jointing planes, and small planes of fracture—most often where three such planes intersect.

DETONATORS were formerly made of mercury fulminate or of the fulminate mixed with potassium chlorate. At the present time detonators are often made of a mixture of mercury fulminate with picric acid, trinitrotoluol, or tetranitromethalamine. The initial detonation is said to be increased by this mixture, so that a cap containing 16% of the quantity of the fulminate formerly used possesses equal efficiency.

*Abstract from *The Chemical Engineer*.

Sulphur Di-Oxide as a Floatative Agent

A unique development of the flotation method of concentration has recently been put into practice on a large scale at the Broken Hill Proprietary Company's mines in Australia. The object is to discriminate by selective flotation between the blende and the galena in the ore. At the present time it is being used in the treatment of the lead-zinc slime accumulated from previous gravity concentration that could not be successfully dealt with by the Delprat process. None of the more familiar floatative agents are employed. The Lyster type of cell is utilized, a number of cells being connected into a series, as shown in the accompanying cut. The American patent No. 1,203,372, issued to Fleury James Lyster of Broken Hill, New South Wales, and assigned to the Minerals Separation American Syndicate, Ltd., claims a process for

blades attached to the pump-shell. The object of the lugs is to disintegrate the lumpy tailing. Tapped into the suction-inlet of the pump is a pipe which is again branched a few inches above the point of union with the suction, the second branch leading from a sulphur-burner. The sulphur-fume is drawn in along with air which enters through the main branch of this pipe, the mixed gases being thus carried into the pump entrained in the pulp-feed. The pulp is delivered to the pump from an agitation-tank, which in turn is supplied by a tailing belt-conveyor, upon which is fed salt-cake in the proportion of 2 to 2½ lb. per ton of the tailing. Salt-

GROUP OF THREE LYSTER CELLS.

"subjecting ores to flotation separation by agitation with the frothing agent in the non-acid solution of the mineral acid salts of metals which form basic hydroxides, and thereby separating the lead sulphide from the zinc sulphide." Four additional patents were granted to Lyster, No. 1,203,373-4-5, for other improvements in flotation. These relate to the use, in one case, of a salt of a mineral acid having an alkaline reaction together with a small proportion of a frothing agent in the solution; for example, sodium carbonate is proposed in conjunction with a frothing agent for lifting out the fine galena from a mixture of lead and zinc sulphides in the ore. In another case he claims promotion of selective action by the introduction of a chloride, such as common salt, along with an alkaline hydrate, the selectivity being more pronounced by using an excess of the hydrate.

The sulphur-dioxide method, as now adapted at the Broken Hill plant, employs centrifugal pumps connected in the series, one taking the original feed-pulp, and one being interposed between each cell. The centrifugal pumps are peculiar in their construction, consisting of a disc-runner with lugs or blades on the sides operating between corresponding concentric rows of similar lugs or

ELEMENTS OF SEAL-SHELL-SHEAR FLOTATION CELL.

cake is the crude sodium sulphate produced in the manufacture of soda-ash. The charge in the agitator is heated to a temperature of 90° before being drawn to the centrifugal pump; thence it is forced through cell No. 1, from which a lead-froth concentrate is delivered. Thence the tailing passes through the second pump, also drawing in air and SO₂, but no more SO₂ is added beyond this point. By the time the solution has reached cell No. 5, the SO₂ has all been evolved from the pulp, and zinc concentrate begins to appear with the lead in the froth. The mixed concentrate from cell No. 5 is returned to the agitator, and once more traverses the first series of flotation-cells. The tailing from No. 5 is heated to a temperature of 120° by steam, and about 18 lb. of sul-

phuric acid per ton of pulp-solids is introduced. This pulp is circulated in the same manner as before through five cells, all those after No. 5 in this second series yielding zinc concentrate of a grade suitable for retorting.

It must be pointed out that in the sulphur-burner a considerable quantity of SO_3 is produced along with the SO_2 , and that consequently the pulp in the first five cells contains a moderate amount of H_2SO_4 . Further details regarding this process, which we understand is due to the inventive ability of Leslie Bradford, will be awaited with great interest. The successful selection of lead sulphide in the Bradford process is mainly the result of intense aeration, in combination with the effect of the sulphur di-oxide in retarding the flotation of the zinc sulphide until the lead is lifted. The use of the salt-cake is to increase the specific gravity of the liquor, the proper density of the medium being frequently a matter of great importance in flotation. The best recoveries from the Broken Hill ores have been accomplished with a solution having a density of approximately 1.05. The addition of the sulphuric acid is significant of local conditions. The Broken Hill ore contains on an average about 3.2% calcium carbonate, which is soft and tends to accumulate in the slime during the milling process. It is reasonable to assume, therefore, that considerable finely divided calcite is present in the slime treated by the Bradford method. The sulphuric acid would liberate carbon di-oxide from this. In the acid flotation process more than 6% of slime will seriously affect, and at times even will prevent, the recovery of the sulphides owing to the fact that most of the calcite is in a state of such minute subdivision that the gas evolved from reaction with the H_2SO_4 forms exceedingly small bubbles, which individually have a low lifting power, and are prevented from coalescing by the viscosity given to the medium by the suspended slime. The addition of the large volume of air in the method worked out by Bradford would overcome this difficulty, and the carbonic acid gas would materially aid the air in separating the zinc sulphide from the acidulated solution.

At the Sulphide Corporation, jigging of the 40-mesh galena is being superseded by flotation, using a Seal-Shellshear machine, the principle of which is shown in the accompanying outline drawing, which makes no attempt to indicate the actual mechanical details. The jet from the feed-boxes produces an exhaust, drawing air downward into the delivery-column below the perforated cast-iron jacket. The stream under pressure due to the head strikes the baffle, which produces, by reaction, sufficient agitation with the entrained air to develop froth that lifts the galena. A small quantity of eucalyptus oil is added to the pulp as a floatative agent. These cells are connected in series, and the tailing from cell No. 5 goes to a Hebbard machine, where the pulp is heated by steam jets to a temperature of 120° , with the addition of sulphuric acid and eucalyptus oil, thus effecting the flotation of the zinc-blende. This method of selective flotation is also said to yield excellent results. The earlier practice at the Sulphide Corporation was to

jig at 5-mesh to recover the coarse lead sulphide, then to re-grind the jig tailing to 40-mesh, and concentrate on tables to obtain more of the galena, after which the total reject from the tables was treated by flotation, yielding a concentrate containing 12% lead. The zinc and lead in the flotation-concentrate were subsequently separated by tabling.

The Romance of Silver

*An interesting lecture on 'Silver: Its Romance and History' was given recently in London by Benjamin White, Fellow of the Economic Society, in aid of the Red Cross Funds. He traced the history of the metal from the earliest times. Referring to the output of silver, he said: "The production of the world amounted in 1914 to 211,000,000 oz., worth, say, £26,000,000, being six times the production in 1869. North America produced 170, South America 13, Europe 15, Asia 6, Australasia 4, and Africa 1 million. Almost nine-tenths of the silver comes from the Americas. It is an extraordinary circumstance that two-thirds of the world's production is absorbed by Asia. In the Middle Ages silver was derived from Great Britain, France, Austria, and Germany. The beautiful color called Saxony-blue was made from the cobalt mines of that country. Three subsequent great epochs may be noted: first, the Spanish discovery of the mineral wealth of Mexico and Peru about the year 1520. Stripped of the glamor of historians, it was a squalid story of massacre and slavery. Many galleons laden with treasure formed part of the Spanish Armada, and were wrecked upon the British coast; secondly, the discovery in 1859 of the Comstock Lode in Nevada. A rush of hardy miners ensued, and fresh finds were made. So much silver was yielded that, coincident with the discovery of the gold in California, bimetallism had to be abandoned, that is, the free coinage of both metals at a fixed ratio to each other had to be given up. The Anaconda mine, in Montana, is the largest producing mine today; its annual output being 9,000,000 oz.; thirdly, in 1904, as a new railway was being driven through part of Ontario, traces of silver were discovered in a railway cutting. Within a few years, from an area only 50 miles in diameter, 30,000,000 oz. of silver was mined in one year alone."

THE DANISH WEST INDIES, recently purchased by the United States for \$25,000,000, were originally bought from France by Denmark in 1733 for a sum equal to \$150,000. The islands are of great beauty and possessed of an almost ideal climate. The soil is extremely fertile, and well adapted for the culture of sugar cane. The only mineral prospects are on the island of St. John, where copper exists in a ferruginous zone that has received no attention hitherto. Deposits of a good grade of yellow ochre are found in the same zone. Limestone exists both on St. John and St. Croix, and is employed in the purification of the cane-juice in the sugar mills.

*The Financial Times.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

OATMAN, ARIZONA

ENLARGEMENT OF THE PLANT AT THE TOM REED.—UNITED EASTERN OUTPUT.

At the Nellie property in the Black Range part of the Oatman district the shaft has reached a depth of 500 ft. and as soon as a station and sump can be cut a cross-cut will be driven to the wide vein. On the 350-ft. level a drift along the hanging wall for a distance of 162 ft. disclosed a leached condition, the daily samples ranging from \$2 to \$3 up to \$35 per ton. The shaft passed into the vein at 360 ft. The vein dips at 45° and, in sinking the shaft, passed through 26 ft. of solid quartz that averaged \$9 per ton. It is the belief of those who have examined the Nellie that the 500-ft. level will prove to be the lower limit of leaching and may contain rich shoots of ore due to secondary enrichment.—Bullion to the value of \$74,500 was shipped from the United Eastern on March 21, the result of 12 days' operation of the 200-ton mill. The mill is now treating in excess of 200 tons daily, and where the ore is soft the tonnage runs up around 225. The No. 2 shaft, through which the ore is hoisted, has lately been connected with the 665-ft. level and sinking will be resumed upon the arrival of an auxiliary hoist.—Five redwood tanks 40 ft. in diameter and 12 ft. high, completing the tankage for the new unit of the Tom Reed mill, have been constructed. Cement foundations for the tanks and crushing-equipment were completed some time ago and the machinery will all be installed within 30 days. Several Allis-Chalmers granulators will be installed, and the twenty 1050-lb. stamps, so long in use, will be discarded. The present output is 120 tons daily, of which 40 to 50 tons is supplied by the new Aztec orebody. The Aztec shaft is one mile from the mill and the ore for the present is transported by auto-truck. Later an aerial-tramway will be installed. The new mills will more than double the output, which for ten months has averaged about \$43,000 per month.—The average of the east drift on the new 600-ft. level of the Big Jim for the first 70 ft. from the cross-cut was \$18.14 per ton. Lately the ore has improved and face samples have run as high as \$144 per ton. Superintendent Keating estimates the mine and mill costs not to exceed \$5 per ton. As soon as the 600-ft. level is opened sufficiently mill-tests will be concluded and plans drawn for a mill. Marcy ball-mills, which have been successful at the United Eastern mill, will be installed at the Big Jim also.—The production for the first quarter at the United Eastern ends March 31, and there is much interest among operators in the forthcoming report, which it is assumed will be issued early in April. Oatman ores are ideal for cyaniding, and the United Eastern is known to have made a high extraction, probably around 98%.

GOODSPRINGS, NEVADA

HIGH-GRADE ORE SHIPMENTS.—JEAN SAMPLER COMPLETED.

At a depth of 20 ft. a winze from the new tunnel in the Platino mine has encountered a 24-in. shoot of high-grade copper ore. Manganese and iron also shows, and a small amount of gold and platinum is present. Superintendent Springer has increased the working force and expects to make a shipment soon.

The Lucky Maid Silver, Lead & Zinc Co. has been incorporated by Las Vegas, Nevada, people to operate a group of

claims adjoining the Green Monster mine. It is planned to install equipment and drive a 200-ft. tunnel to intersect the orebody exposed near the surface. Thomas Clark is president; H. H. Johnson, secretary.

The output of the Yellow Pine property is again becoming normal, following two months of reduced output because of severe weather and bad road conditions. The company is ready to start shipments from the lease taken over last fall from Griffith & Tuck, and generally known as the Charlestown property. The main orebody is yielding ore running 45% zinc.

The Jean sampler has been completed and Manager J. B. Jensen expects to start the machinery at once. A temporary track will be constructed to facilitate ore shipments until the Salt Lake Railway builds the necessary sidings. Large quantities of ore are already in the bins, and many large producers are prepared to ship.

J. R. Newberry, of Riverside, California, has extended the lease of Huston Cornelson on the Tam O'Shanter another year. It is provided, however, that a hoist, blower, and other equipment must be installed within 30 days. Several shipments of silver-lead ore have been made recently.

Charles Kalters and J. Robinson have purchased the Joseph Conaway lease on the Singer, an important producer. The lease on the Annex claim has been acquired by H. W. Ball from Peter H. Nelson and Fred W. Schwanbeck.

MONTERREY, MEXICO

NO FURTHER EXTENSION OF TIME TO FOREIGN OWNERS TO BE GRANTED BY CARRANZA.

The de facto government of Mexico has refused to make any further extension of the time-limit for the resumption of operations on mining properties in Mexico and it is stated that the work of confiscating all delinquent properties will be proceeded with as rapidly as possible. The original decree requiring that there be a renewal of operations at idle mines fixed the time for the Government to take over these properties, at November 14, 1916. In response to petitions of many American and other mine-owners the date was extended to March 14, 1917. According to the provisions of a new decree recently issued by the Government on the subject, the mine-owners of this country are divided into three groups. The first embraces those whose properties are now being worked; the second, those who applied for an extension of time in which to renew operations, and the third, those who have entirely ignored the decree. Leniency will be shown the mine-owners who belong to the first and second groups, it is officially stated, provided they furnish the department of fomento, prior to April 1, a detailed statement of what efforts they have made to comply with the decree. Those who are embraced in the third group will receive little consideration unless they come forward at once with explanations that are deemed satisfactory to the Government. It is stated that most of the larger American mining concerns, particularly the American Smelting & Refining Co., are in good standing with the Government with respect to the efforts that have been and are being made to operate their respective properties in this country, but there are hundreds of small mine-owners who for one reason or another have been forced to abandon their holdings and have no means of complying with the Government's decree.

PACHUCA, MEXICO

THE SANTA GERTRUDIS COMPANY REPORT, LAST QUARTER OF 1916.

The general manager's report on the working operations of the mines for the quarter from October 1 to December 31, 1916, is as follows:

The mill during the above period crushed 33,243 dry short tons of ore.

Value of bullion produced	£60,967
Less working expenses (including development and shipping and selling)	57,631

Estimated profit at mines£ 3,336

There were no expenditures for construction.

MINE DEVELOPMENT. A total of 2467 ft. of development was accomplished throughout the mine, of which 981 ft. was in payable ore, 718 ft. in vein below pay, and 768 ft. in country rock. During this period the countershaft was unwatered below the 21st level, the recovery of all equipment accomplished, and subsequently the shaft was again allowed to flood to the 20th level.

Two hundred feet of driving and cross-cutting was accomplished during this period, most of which was in country rock and none of which was in pay ore. All the work tended to confirm the earlier evidence that this vein breaks up into numerous small stringers, of no value, before reaching this level. No further development work will be done at this horizon, and the workings have been permitted to flood to the natural water-level, which is 30 ft. below the 4th level.

The hanging-wall orebody lying between the North and No. 8 veins, and already opened up on the 14th and 16th levels, has now been proved to extend to the 13th level. Cross-cut N 2058 sampled 6.59 dwt. gold and 43.4 oz. silver for a width of 6.9 ft. while the cross-cut S, at the same parallel sampled 3.39 dwt. gold and 17.5 oz. silver for a width of 8 ft. The limits of mineralization have not yet been reached. Development work throughout the mine has been considerably reduced to conform to the conditions of curtailed production.

The average milling rate for the period under review was 33% capacity. This low rate was due to a shortage of cyanide, which, as yet, has not been relieved. Milling operations were completely suspended for 36 days and were carried on at a reduced rate during the remainder of the period. All work, including mine development, which is not immediately necessary for the present reduced production, has been suspended, pending an improvement in conditions pertaining to cyanide delivery.

Increased cost of living is making itself felt here, as elsewhere, in a gradually increasing wage schedule. The present scale is fully 25% higher than that of 1912, which it has been customary to take as normal.

SUTTER CREEK, CALIFORNIA

THE OLD EUREKA SHAFT NOW CLEAR DOWN TO THE 1760-FT. LEVEL.—OLD MINE NEAR PLYMOUTH TO BE OPENED.

The working force at the Old Eureka mine has been increased gradually, under the management of T. Walter Beam, until it now totals about 60 men. The shaft has been cleared to a depth of 1760 ft., and as soon as the debris remaining in the bottom of the shaft has been removed, work will be started cleaning out the old drifts and re-timbering the mine for future development. With the equipment now installed, prompt results are anticipated. Considering the delay in receiving the electrical machinery and the necessity for using a single-reel hoist and small skip, good headway has been made in getting the water all out of the shaft. The large platform that is on a level with the new engine is in course of construction. This platform rests on the 32-ft. concrete piers at the collar of the shaft, and the low ground around the

collar of the shaft will be filled-in with the waste hoisted from the mine, so that the main buildings will be on level ground and easily accessible by road from the county highway.

W. E. Darrow, president of the California Slimes Concentrating Co., recently has secured a lease, covering the privilege of working the tailing that will flow from the new Argonaut mill to the large Eastwood dam near Jackson, which option he has assigned to his company, that already is successfully operating tailing-plants at the Fremont and Bunker Hill mills. During the week, Mr. Darrow has been engaged in transferring the electrical machinery from the Poundstone mine, the East Eureka, east of Sutter Creek, to his new plant, which will doubtless be ready for operation soon after the Argonaut mill begins crushing. Darrow is the inventor of a gold-saving machine that is a model of its kind, and the stockholders in his company receive frequent and substantial dividends.

B. Levaggi, of the Levaggi Estate Co. of Plymouth, has started a number of men to work on the Monte de Oro mine, two miles north of Plymouth. There is a large outcrop of quartz on this claim, formed by the intersection of three well-defined veins. The north end of the claim was prospected during former work by a cross-cut tunnel 785 ft. long, giving 200 ft. of backs, and some work has also been done by means of open-cuts on the south end of the claim. There is a 10-stamp mill on the ground, which Levaggi expects soon to get into operation. Some rock of good grade is exposed and ready for mining.

C. E. Bunker, who for several years was superintendent at the Keystone mine in Amador City, has been appointed to fill the vacancy caused by the resignation of E. Hampton, as superintendent of the Bunker Hill.

Shaft repairs are in progress at the Plymouth Con. Mines at Plymouth, and during this work a number of employees have been laid off temporarily.

Another strike of pay-rock has recently been made at the Onelda mine, on the lowest level, and while the extent of the new orebody has not yet been determined, assays are said to range from \$16 to \$46 per ton. Further development work is being urged vigorously.

GOLDFIELD, NEVADA

GOLDFIELD CONSOLIDATED FLOTATION-PLANT.—CORE-DRILLING ON JUMBO.

The first unit of the Goldfield Consolidated flotation-plant has been in operation about ten days, and is treating ore from the Atlanta and Consolidated mines. A good extraction is reported. The Consolidated company is steadily increasing development work in the Laguna and the deeper levels of the Mohawk. Fourteen sets of lessees are also at work.

A suit against the Yellow Tiger Mining Co. for \$18,800, attorney's fees, and costs of the action, has been brought in the district court by T. S. Ellis, of Denver, Colorado. It is stated that various notes for money were advanced the company by T. Finley Wyle, of Denver, said notes having been assigned to plaintiff, who also advanced various sums to the company. The Yellow Tiger mine has been idle several months, and a movement is under way for re-organization of the company.

Water is causing trouble at the Cracker Jack and Silver Pick properties. In the latter a heavy flow has been struck in the west workings, but the pumps are said to be handling it without serious difficulty. In the Cracker Jack the water has risen to above the 200-ft. level, drowning the pumps and stopping all work. Additional pumping equipment has been ordered by H. G. McMahon, the manager.

Five carloads of ore is shipped monthly from the Great Bend to Utah smelters, the ore averaging around \$40 per ton, all of which is from the 260-ft. level, where the vein is 4 ft. wide. The management plans to remodel the small mill, as a considerable tonnage of ore is blocked out.

The core-drill operating from the 1017-ft. level of the Jumbo Extension has gained a depth of 230 ft. and is advancing 7 ft. per day. It is expected to enter the shale-alaskite contact soon. Small shipments of \$30 ore are being maintained from the old workings. Reports from the Copper Mountain mine, lately taken under bond, are encouraging. Including lessees, 100 men are at work, and considerable ore is going to the smelters.

JUNEAU, ALASKA

A 50-STAMP MILL FOR SAMPLING.—LOCAL ENGINEERING SOCIETY MEETS.

The 50-stamp pilot-mill of the Alaska Juneau Gold Mining Co., at Juneau, was shut down on March 15, pointing to an early date for the starting of the new 8000-ton milling-plant. The management reports the mine in condition to deliver such tonnage as the mill will be able to handle upon starting up—probably around 1000 tons per day. The railroad between the mine and mill has been wholly re-constructed, ending in a steel trestle at the mill. Two of the bents of this trestle were designed to be built in the coarse-crushing plant of the pilot-mill, hence it was necessary to wait until that mill was shut down before completing this trestle. This has been done, and the railroad can now handle the ore. The train crews are working on the new rolling-stock.

One unit of the new mill is practically complete, and barring possible delay in receiving the small amount of machinery still due, the management expects the mill to be in operation shortly after April 1.

The members of the Alaska Mining and Engineering Society, members of the Alaskan Territorial Legislature and the Territorial Senate, on March 17, made a trip through Perseverance mine, the guests of the Alaska Gastineau Mining Co. After a trip through the mine, the party, numbering 125 in all, was banqueted at the mine mess-house.

C. T. Jackson, assistant general manager for the Alaska Gastineau Co., and president of the Alaska Mining and Engineering Society, presided. Interesting papers were read on 'Mining System and Costs at the Perseverance Mine,' by B. B. Nieding, superintendent; 'Underground Trammeling Operation and Costs,' by R. R. Van Valkenburg; 'Methods Employed in Stope-Surveying,' by Ralph Healy, engineer at the mine; 'Mine Power Supply,' by W. S. Pullen, chief electrician; 'Mine Change-House,' by D. J. Argol, assistant superintendent; and 'Mine Accounting System at the Perseverance Mine,' by Ed Doherty, accountant at the mine.

COBALT, ONTARIO

SATISFACTORY DEVELOPMENT IN THE TEMISKAMING.—FLOTATION AT THE TRETHEWEY.

The main shaft of the Temiskaming mine has reached the 1600-ft. level and has connected with the drift at that depth which was run into Temiskaming from the Beaver workings. Excellent air circulation has been established and exploration and development at and below the lower contact will be pushed forward vigorously. A cross-cut will be run to tap the high-grade vein which is known to exist on the Beaver, that runs directly toward the Temiskaming. Meanwhile operations on the Beaver are proving the high-grade value of the ore to be consistent at the lower contact, and already a large quantity of 1000 to 2000 oz. ore has been mined at this level.

COBALT. The Beaver has driven about 40 ft. on the first high-grade vein found on the 1600-ft. level. A short distance in, a second vein was found cutting across the original discovery at the lower contact. Near the intersection and between the two veins several feet of wall-rock carrying leaf silver was found. The second vein looks about as promising as the first, being several inches wide of fairly high-grade ore with accompanying milling rocks in the walls. A winze will be started close

to the intersection. The contact is close to the roof of the drift, so no raising will be done at present.

The rock-house and hoist-house at No. 1 shaft of the Cordova Mines Co. caught fire at about 2 a.m., March 13. The building was a mass of flames before the fire was discovered, and the strong wind swept the fire across to the mill so rapidly that nothing could be done to prevent its destruction. The efforts of the management therefore were directed towards saving the adjoining buildings, and in getting three imprisoned miners out of the shaft. After the fire was smothered at the collar of the shaft, and the loose ground broken down, water and air-lines were laid through a winze and sub-level and the fire below the collar was extinguished. Air was then forced into the shaft, and after ten hours strenuous work, the rescue party found the missing men. They had taken refuge in an underground magazine, from which they had excluded all smoke by chinking the cracks.

PORCUPINE, ONTARIO

LABOR SHORTAGE AND MILLING EXTENSION AT THE HOLLINGER.

Eleven hundred men are employed at the Hollinger Consolidated as compared with 1300 six weeks ago. The shortage of labor is acute and there appears to be no immediate relief in sight. By the first of June, however, it is anticipated that the capacity of the mill will be raised another 1000 tons daily, or a total of 2700 tons, and it is expected the 3500 tons aimed at will be reached before the end of the coming summer.

The embargo on freight is lessening and as a result 12 carloads of machinery arrived in a single week. Eighty stamps of the new addition to the mill are in place, two tube-mills in position, and practically all of the building is completed. The Hollinger dividend has been temporarily reduced from 1% every four weeks to 1% every eight weeks. This will continue only until after the completion of the big expansion. During 1916 the Hollinger produced over \$5,000,000.

The main drift at the 1000-ft. level of the McIntyre-Porcupine is 900 ft. long and is in ore all the way. The vein continues 28 ft. wide and maintains an average grade around \$20 to the ton. Costs are a little over \$4 per ton, and the mill-heads are being held down to about \$10.60 per ton. The mill is treating at the rate of nearly 600 tons daily and the profit is estimated at nearly \$4000 per day. It now appears as though the McIntyre will crowd the Dome Mines as the second largest gold mine in the Dominion of Canada. About 60 machines are employed and it is the intention of the management to continue the drift at the 1000-ft. level through every property included in the consolidation, which comprises the McIntyre, McIntyre Extension, Jupiter, and also the Plenaum on which they hold an option. The ore-zone may thus be opened up for approximately one mile in length.

Contrary to the common belief, Hollinger reports will continue to be issued every four weeks, as heretofore, although the dividend periods will be eight weeks apart.

KIRKLAND LAKE, ONTARIO

NEW POWER-PLANT IN OPERATION.—TOUGH-OAKES INCREASING OUTPUT.

Power has been turned on at Kirkland Lake and already mining operations are showing marked improvement. The Tough-Oakes mill is running at full blast and is expected to show a large increase over the 1916 production which was \$707,000. The Teck-Hughes mill is also in operation and will treat about 75 tons daily. A new mill is in the course of installation at the Lake Shore mine, and numerous small mine plants are being installed at the various properties. Very rich gold ore is being encountered in the drift at the 500-ft. level of the Kirkland Lake Gold Mines, Limited, and the shaft will be continued to the 600-ft. and deeper levels.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

The Alaska Mexican Gold Mining Co. reports for February as follows:

Tons ore crushed, 6755; tons concentrate saved, 182.98; estimated value of gold in concentrate, \$10,029.39. Realizable value, \$9929.10. Operating expenses, \$8796.90. Estimated operating profit, \$1132.20. Construction expense, \$3127.53. Estimated loss, \$1995.33. Other income, \$4919.78. Yield per ton of ore, \$1.48. Stock of broken ore, 5693 tons. The Mexican mill also crushed 6552 tons of ore from the United Co.'s Ready Bullion mine. This company's proportion of Central and Combination Development is included in the construction expense.

The Alaska United Gold Mining Co. reports for February as follows:

The Ready Bullion mill ran 27 days, 19 hours, and 2 minutes. On water-power 4 days; electric-power, 23 days, 19 hours, 2 minutes. The 700-Ft. Claim mill ran 26 days, 20 hours, 45 minutes, all by electric-power.

	Ready Bullion mill	700-Ft. mill
Ore crushed, tons	21,917	20,090
Mexican mill	6,552	
Total	28,469	
Free gold	none	nbne
Concentrate saved, tons	639.41	464.86
Estimated gross value concentrate....	\$54,411.25	\$37,504.91
Realizable value	53,867.14	37,129.87
Operating expense	42,950.81	66,087.23
Estimated operating profit	\$10,916.33	*\$28,957.36
Construction expense	8,459.65	7,843.12
Total	\$ 2,456.68	*\$36,800.48
Other income	\$ 2,040.75	\$ 2,040.74
Yield per ton of ore milled	\$1.91	\$1.86
*Loss.		

The Alaska Treadwell Gold Mining Co. reports for February as follows:

In the 300-stamp mill 225 stamps were run 27 days, 2 hours, and 6 minutes; running on water-power 8 days, 5 hours, and 10 minutes, and an electric-power 18 days, 20 hours, and 56 minutes.

Ore crushed, tons	34,790
Concentrate saved, tons	692.04
Estimated gross value of free-gold	\$ 6,687.86
Estimated gross value of concentrate	56,183.94
Total production	\$62,871.80
Total realizable value	62,243.09
Operating expense	38,100.90
Estimated operating profit	\$24,142.19
Construction expense, etc.....	13,543.52
	\$10,598.67
Other income	\$11,838.74
Total	\$22,437.41
Yield per ton of ore milled.....	\$1.81
Stock of broken ore decreased, tons.....	8,415

The diamond-drill down-hole No. 6 on the 2300-ft. level was advanced 474 ft. It showed an average value of \$0.59.

The Alaska Juneau company recently completed a 1500-ft. raise, cut at an angle of 56° above the horizon. This is a somewhat unusual accomplishment.

ARIZONA

MOJAVE COUNTY

(Special Correspondence.)—The new equipment at the Tom Reed mill consists, not of Marcy ball-mills, as stated in the issues of March 24 and 31, but the coarse crushing will be done in a 5 by 6-ft. Allis-Chalmers ball-granulator, followed by two 5 by 6-ft. Allis-Chalmers ball-pebble granulators.

Oatman, March 26.

George F. Beveridge will place a hoist on the east shaft of the Diana mine in the Chloride district. The shaft is down 40 ft. and will be sunk to 500 feet.

YUMA COUNTY

WENDEN. About six miles south of Wenden, Michael McCormick has discovered a large vein of mineral that is said by the State School of Mines to be magnesite. The vein is from 30 to 100 ft. wide and outcrops for some distance.

The Fortuna mine, which was worked with success for years by Chas. D. Lane, of San Francisco, and which has been idle for a long time, is again being prospected, with a view to larger operations.

CALIFORNIA

BUTTE COUNTY

The Oro Light, Water & Power Co. on March 26 recorded a deed conveying 3900 acres of dredging land in Butte and several thousand acres in San Joaquin and Calaveras counties to the American Gold Dredging Co. The latter corporation was organized to take over and dredge the lands of the Oro corporation after it sold its power holdings to the Pacific Gas & Electric Co. At the same time the American Gold Dredging Co. filed a deed of trust, covering its holdings, in favor of the Savings Union Bank & Trust Co. of San Francisco to cover a bond issue of \$1,000,000 to finance the dredging corporation's operations.

OROVILLE. Announcement has been made, says the *Register*, that rich ore has been encountered at the 450-ft. level of the South Banner mine. The vein at this place is 9 ft. wide and the ore runs \$20 to the ton. Richard Phillips is general manager. There are five stamps now installed and five additional stamps are being constructed at Grass Valley. In addition to this, pumping machinery has been ordered in Grass Valley. The pumping machinery will be installed at the Amoskey vein and the work of de-watering that shaft will be started.

EL DORADO COUNTY

(Special Correspondence.)—Oakland people are becoming heavily interested in properties near Placerville. The Livingston gravel mine has been taken under bond and option, with work to start in 30 days. Years ago the mine yielded rich gravel at the surface. The Oakland syndicate has arranged for the driving of a 200-ft. drift from the 700-ft. level of the Pyramid mine, in expectation of intersecting the main orebody. The work will be done by contract.

The Teddy Bear Mining Co., of Seattle, has erected a small stamp-mill at the Teddy Bear, near Nashville. A good ton-

nage of free-milling ore is available. It is planned to carry the workings deeper this summer. Another Seattle corporation, the Deep Levels Gold Mining Co., has taken over the Los Padres mine, at El Dorado.

Placerville, March 28.

INYO COUNTY

J. Irving Crowell, of Los Angeles, has petitioned the State Water Commission for 1½ cu. ft. per second of the waters of Can Springs, 15 miles south of Rhyolite, Nevada, for use at gold, silver, and lead mines. A pipe-line half a mile long is proposed to convey the water to the place of use.

NEVADA COUNTY

The owners of the Red Ledge mine, two miles from Washington, on the road to Nevada City, are again taking out high-grade gold ore. The formation is slate that is intersected by small dikes of albite feldspar, and it is with the intrusions of albite that the gold occurs. Some pieces taken from the Red Ledge were worth several hundred dollars.

The case of *Williams v. Brunnier*, involving the title to one of the claims in the Conlan group of mines in Grass Valley mining district, has been decided by Judge George L. Jones in favor of the plaintiff. The plaintiff re-located the claim, alleging that the work for the year 1915 had not been done. Evidence introduced by the defense was to the effect that the work had been paid for, but evidence of its having actually been done was lacking, and the court awarded the claim to plaintiff.

PLUMAS COUNTY

Recent statements concerning a change of control and management in the Engels Copper Co. are officially stated to be wholly without foundation. There has been no change and there is none anticipated. Nor has there been any transfer of control in this company. John Reinmiller has been superintendent for nearly two years; E. E. Paxton has been for three years the general manager and will continue to direct the operations.

The Plumas Grass Valley Mines Co., of San Francisco, has made application to the State Water Commission for 2 cu. ft. per second of the waters of the south fork of Feather river for the development of power to be used in mining. The total fall to be utilized is given as 250 ft., and it is proposed to develop 50 horse-power. A ditch and pipe-line 4000 ft. long are proposed to carry the water from the point of diversion to the place of use and the estimated cost is given as \$4000. The mine consists of an ancient auriferous gravel channel, the principal development is at and near Grass Valley, 10 miles north of La Porte.

TRINITY COUNTY

The State Water Commission has been petitioned by Frederick F. Holley of Peanut for 12 cu. ft. per second of the waters of Forest Glenn, or Mud creek, tributary to the south fork of the Trinity river for hydraulic placer mining. A dam of rock, brush, and timber is proposed to divert the water into a ditch and pipe-line three-quarters of a mile long, the estimated cost of the diversion to be \$1500.

IDAHO

OWYHEE COUNTY

The Sinker tunnel has reached the veins of War Eagle mountain that were worked with profit in their upper parts some years ago. It is also reported that the Golden Cycle mine near De Lamar, has found high-grade ore.

NEVADA

MINERAL COUNTY

H. G. Cannon, of Sweetwater, has made application to the California Water Commission for 5 cu. ft. per second of the waters of Green and Ferris creeks, tributary to West Walker river in Mono county, California, for mining purposes. The

proposed diversions are to be made by means of two rock or concrete dams and two conduits, each two miles in length.

CHURCHILL COUNTY

It is understood that work is about to be resumed on the Carpenter nickel mines, at the head of Dixie valley says the *Review-Miner*.

A watchman has been employed on this property for many years, and for a time, the difficulty of having the nickel ores smelted prevented active work. Preparations now are being made to put the property in shape, and again begin taking out ore, which in the event of war in which this country might be involved, would be of great value in furnishing a metal which Germany has for many years been supplying this country. Nickel deposits, of considerable extent, have been discovered from time to time in this State, but because the nearest smelters at the time were in Canada, there was not much incentive to work them, although with a high price on the metal, they would probably become paying propositions.

ESMERALDA COUNTY

GOLDFIELD. The Spearhead mine management announces a strike of rich ore on the 910-ft. level of that mine, where a 3-ft. vein has been found by cross-cutting.

HUMBOLDT COUNTY

ROCHESTER. The discovery of a large body of ore in the mines of the Rochester Mines Co. is announced.

Stopping in the old Four J block on the 420-ft. level developed the ore, which is 25 ft. wide. This lies in the hanging wall, and west of the ore removed by the former lessees on the block. The discovery of this orebody has added a large tonnage to the reserves developed. Reports from all parts of the property are to the effect that development work is progressing with satisfactory results, and that the usual supply of good ore is being mined.

MINERAL COUNTY

(Special Correspondence.)—The Western Ore Purchasing Co. has arranged to treble the capacity of its Hazen sampler, bringing it up to 900 tons daily. At present the plant is glutted with ore and the company is forced daily to refuse shipments. Manager F. M. Manson says that Candelaria and other old camps are again producing heavily.

H. K. Skinner is preparing to start shipments of silver-lead ore from the Badger mine, in the Marietta section. At a depth of 100 ft. the 186-ft. tunnel has intersected a small vein assaying \$125 per ton, 60% of the value being in lead. A little gold also shows. At the Miller property nearby, similar ore is exposed.

A carload of gold-copper ore is being shipped daily from the Copper Belle group at Contact, 26 miles from Mina. The ore is mined from a glory-hole, where the deposit 40 ft. wide, assays around \$35 per ton; 10,000 tons of shipping-ore is said to be exposed.

Mina, March 26.

NEW MEXICO

SOCORRO COUNTY

The Oaks company is making a shipment of ore to a custom-mill from the Eberle and Clifton mines. No stopping has been done on either property to date, all shipments being from development work. Large bodies of ore are being blocked out for mining on a larger scale when the facilities have been completed.

From operations covering the first half of March the Mogolion Mines Co. produced 13 bars of gold-silver bullion and four tons high-grade concentrate. New developments on the lower levels are adding to the ore-reserves.

At the Pacific mine a crew of over 20 men is employed. The work is being pushed as much as the allotment of power from the Socorro Co.'s plant will permit. In addition to develop-

ment of lower levels, stoping above the adit-tunnel was recently started, and the wire-rope tramway to Socorro's mill is in daily operation.

The initial shipment of ore to the custom-mill from the Maud S. mine, under option to the Oaks company, will likely be made the present week.

(Special Correspondence.)—A. H. G. Palmer, manager and one of the owners of the Alberta group of claims, adjoining the Socorro's property, has a party of prospective investors here inspecting the ground. Rumor is current that an active campaign of development will be started.

The Oaks company is rustling burros to make another shipment of ore to custom-mill. The ore was obtained in course of development work on the Clifton and Eberle mines.

Socorro Mining & Milling Co. shipped 14 bars gold-silver bullion to the mint from operations covering the first half of March. Its aerial wire-rope tramway from the Pacific mine is in operation, transporting a good tonnage of ore from the latter property.

Preliminary work at the Maud S. mine is well in hand, and some prospecting-mining is being done to determine the best points at which to begin active development. Much is expected of this property, in view of its excellent record of production in the past from only a limited exploration of its veins. The Oaks company is exercising a bond and lease on the mine.

Mogollon, March 23.

OREGON

JOSEPHINE COUNTY

(Special Correspondence.)—Near Takilma the Queen of Bronze mine is working 50 men, and producing a good grade of copper ore. The Waldo and Cowboy copper mines are also being worked. The Logan hydraulic mine is being prospected with churn-drills. It is from 30 to 40 ft. to bedrock, and the gravel is mostly small, so good headway is being made. The hydraulic-pit at this mine is 500 by 1000 ft. One elevator is in operation working under a head of about 250 ft. Ten men are employed. Chrome mines in this vicinity are active.

Waldo, March 26.

TEXAS

ARCHER COUNTY

(Special Correspondence.)—There is much activity among mining men in securing leases upon large tracts of land in this region, where deposits of copper ore are known. John Eilman, of Lander, Wyoming, is preparing to install machinery with the view to developing copper deposits that are found upon a tract of 2300 acres that he recently leased. The fact that the ore occurs as nodules in a clay formation has caused the dredging method of mining to be adopted. The clay in which the ore is found is put through the washing-process and in that manner the almost pure copper is obtained ready for shipment. Copper ore-buying agencies are now established in all of the towns adjacent to the copper-bearing district and these concerns are shipping considerable quantities of ore.

Archer City, March 26.

WASHINGTON

FERRY COUNTY

(Special Correspondence.)—The width of the vein encountered by the Lone Pine-Surprise Consolidated Mining Co. in the Last Chance shaft is now determined to be about 5½ ft. The vein is solid and averages \$13 per ton. The mine is equipped with a 514-cu. ft. Ingersoll-Sergeant duplex air-compressor, with cylinders 12 by 12 by 18 in., a Vulcan hoist and ¾-in. round wire-rope, a 90-hp. Pacific Engine & Boiler Co.'s boiler. The machinery is well housed, and there are an office, blacksmith, and carpenter shop on the ground. The head-frame is 37 ft. high. The shaft has a 4½ by 4½ ft. hoisting-compartment and a

3½ by 4½-ft. manway and pumping-compartment, and the ore and waste are hoisted in a self-dumping skip, a special device in the head-frame being provided for this purpose. A drift is being driven south-east on the vein, from which the ore-loaded cars will be run to the station, backed over a 15 by 15 by 12-ft. pocket and dumped. An aerial-tramway is under consideration, its purchase awaiting arrangements for right-of-way and construction of ore-bunkers in Eureka gulch, for the delivery of the ore to railway cars.

The Northport Smelting & Refining Co. is sinking a double-compartment working-shaft on the Lone Pine vein, now down nearly 700 ft. Shipments from the Lone Pine for the week ended March 22 amounted to 350 tons. During the same period Knob Hill shipped 240 tons.—Work has been resumed in the Belcher mine, in the Belcher mining district.

Republic, March 27.

STEVENS COUNTY

(Special Correspondence.)—The discovery of a great deposit of magnesium carbonate is reported from Valley. There is said to be not less than 4,000,000 tons in the mass. The mineral differs in every respect, except composition, from the California magnesite. It is coarsely crystallized, and slightly bluish or grayish in color, looking like some rather coarse-textured marble. It contains only a small amount of lime and silica, though the iron content is just right to make the refractory bricks and linings used in metallurgical furnaces. The American Mineral Production Co. has commenced to ship the crude mineral, and has contracted with the Schaeffer Co. of Tiffin, Ohio, for calcining furnaces and complete plant. An average analysis of this magnesite is: silica 0.8%, alumina 0.4%, iron-oxide 2.7%, lime 3.3%, and magnesium carbonate 92.1 per cent.

Valley, March 26.

CANADA

ONTARIO

A few days ago the report of a fabulous strike of gold in the Hollinger mine was circulated. The truth is that a streak of very rich ore was actually found in the Hollinger mine, but it was of no such dimensions and importance as the reports had led many to believe. The strike was made on the 400-ft. level, where a streak of ore one-half inch wide, a foot high, and 6 ft. long was found crossing the vein. This streak, although not large, was nevertheless nearly all gold. The vein-rock in the vicinity of the pocket was also rich in gold.

YUKON TERRITORY

The report of the Canadian Klondyke Mining Co., showing that it has been able to maintain an unbroken period of dredging operations in Alaska throughout the winter will result in greatly increased earnings for the various Alaskan gold dredging companies. The previous operating record of this company was 120 days for the entire year. The Yukon Gold Co. established a new record last year when it operated in the Yukon district for 180 days. The Canadian Klondyke Co. is a subsidiary of the Consolidated Goldfields of South Africa, Limited, and the method used this year was a new system of thawing with steam. Two of the largest dredges of this company were used, of a capacity of 17-cu. yd. buckets on each dredge. The results have been so satisfactory that the dredging capacity of the company will be increased immediately. The Alaska Mines Corporation has been experimenting with this method and it was thought that this company would be the first to apply it but the Dawson people have taken the initiative.

CHILE

The American Metal Co. is represented in Antofagasta by a group of engineers who are making a detailed study of the Mantos Blancos mining region, about 70 kilometres (43.4 miles) along the railroad to Bolivia. These are the preliminaries of what may be a big mining negotiation which will

be of great importance for the Department. The mines belong to Don Carlos de la Fuente and the Sociedad Chilena de Fundicion.

A mining company has been formed at Iquique under the name of Huanillo. It owns a large deposit of iron (magnetite) that has recently been discovered. This large deposit is of the best class of iron ore and does not go below 75%. Engineers have calculated that there are over 300,000,000 tons. The deposit is situated in the province of Tarapaca, 10 kilometres (6.2 miles) from the coast.

The first shipments of copper ores from the famous Queuco mines have arrived in Temuco. The owner, Sr. Pedro Rosas, who is also the administrator of a number of the mines, says that he has shipped 40 tons to Temuco and expects to complete 200 tons in March, as the transportation had to be stopped during the months of January and February on account of the harvests. The ore which has been extracted contains 45% copper.

Marco Emilio Corvalán has installed a smelter in Cabildo, using a reverberatory furnace of his own invention. It is 15 metres (48.3 ft.) long by 6 metres (19.3 ft.) wide and is provided with ten hoppers for charging the furnace and with a 6-metre (19.3 ft.) stack, says *El Mercurio*. Heat is supplied by four burners, also of a type invented by the owner, using petroleum. The first test lasted five consecutive days and nights without the furnace showing any signs of failure, the products being 380 tons of copper matte assaying 55.72% copper. The slag, which ran out continuously, was glassy and contained a very small percentage of copper (0.24%) and was carried away by a current of water to cars that carried it to the dump. The average grade of copper in the ores treated, including the fluxes, during this test was 2.5%. Large quantities of ore are being received which is stacked in piles of about 500 tons, already mixed with the necessary fluxes.

SOUTH AFRICA

Glynn's Lydenburg (Ltd.) in the Transvaal, reports for February as follows: Tons milled 3870, estimated value £7286; estimated profit £2919.

The Transvaal Gold Mining Estate (Ltd.) reports for February: tons milled 15,000; estimated value £30,630; estimated profit £8338.

Rand Mines (Ltd.) sends out the following report of operations for February:

	Tons milled	Esti- mated value	Esti- mated profit
Modderfontein B Gold Mines, Ltd..	40,500	£87,379	£47,442
New Modderfontein G. M. Co. (Ltd.)	53,200	121,506	65,631
Rose Deep, Ltd.....	56,300	63,287	14,597
Goldenhuis Deep, Ltd.....	54,000	66,691	12,794
Nourse Mines, Ltd.....	36,100	54,058	10,048
City Deep, Ltd.....	59,000	113,681	55,200
Village Deep, Ltd.....	45,600	68,577	16,785
Ferreira Deep, Ltd.....	47,560	80,792	29,908
Robinson Gold Mining Co., Ltd....	51,600	59,725	22,087
Crown Mines, Ltd.....	173,000	233,730	65,791
Durban Roodepoort Deep, Ltd....	25,200	34,368	3,893
Bantjes Consolidated Mines, Ltd..	20,230	19,513	*4,368

*Estimated loss.

In the City Deep, Ltd., the profit includes £2114 profit-accumulations.

The increased loss for the month in the Bantjes Consolidated Mines, Ltd., is due to low grade of ore mined, small tonnage milled, and some abnormal expenditure; also cost of increased native force from which little results have been obtained. The native labor position is now satisfactory, and incline shaft repairs completed. The March tonnage is expected to be higher and 6 additional leader stope-faces will be available for mining within 5 to 6 weeks. Payable value continues to be exposed in portions of leader development.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

MORTON WEBBER is here.

E. W. MILLS has gone to Peking.

LOUIS A. WRIGHT is at Santiago, Chile.

W. W. MEIN has returned to New York.

WALTER G. PERKINS is at the Palace Hotel.

OTTO SUSSMAN has returned to New York from Joplin.

D. M. HYMAN of New York was in San Francisco this week.

A. W. EDELEN is returning to Mexico City, Mexico, in the interest of the American Smelting & Refining Company.

ROSS HOFFMANN has returned to Petrograd from Central Siberia.

SPENCER C. BROWNE, of the Nickel Corporation, is here from New York.

JOHN H. MACKENZIE is at Juneau and will remain there until the end of May.

E. S. PETTIS is in Chicago in the interests of the Oliver Continuous Filter Company.

A. E. WHEELER, in charge of the Tanganyika smelting operations is visiting Montana.

L. D. RICKETTS is so seriously ill that he has had to abandon his expected journey to Chile.

W. B. DENNIS has been elected a member of the Oregon Bureau of Mines and Geology Commission.

E. HAMPTON, who recently resigned as superintendent of the Bunker Hill mine, at Amador City, has gone to Nevada City.

M. WADA, general mill superintendent for the Ashio Copper Mines, Japan, is making a metallurgical tour in this country.

OTTO F. HEIZER is general manager for the Louisiana Consolidated Mining Co. that is re-opening the old Tybo mine, in Nye county, Nevada.

FREDERICK LAIST and WILLIAM WRAITH are on their way to Chile, where they will inspect the Potrerillos mine of the Andes Copper Company.

CHAS. G. YALE is seriously ill at his home in Oakland as the result of being run down by an automobile in Oakland on the evening of March 26.

TATSURO OTAGAWA, of the Department of Mining of the North-Eastern Imperial University of Japan is visiting the mines of Utah and Montana.

H. Y. EAGLE, S. WARD HAAS, and P. E. WELDY are constructing engineers under A. E. WHEELER, of the new smelting plant of the Union Minière, or Tanganyika company, in the Belgian Congo. They are in New York at present.

J. MORGAN CLEMENTS, mining geologist and engineer, will have charge of a survey of the mineral resources of the Far East, including China and Siberia, under the auspices of the Bureau of Foreign and Domestic Commerce, at Washington.

THE second annual meeting of the Pacific Division of the American Association for the Advancement of Science will be held this year at the Stanford University, California, during the period, April 4 to 7. Among the scientific societies which will also convene in conjunction with this meeting are the Astronomical Society of the Pacific, the Pacific Coast Section of the American Mathematical Society, the American Physical Society, the California Section of the American Chemical Society, the Cordilleran Section of the Geological Society of America, the Seismological Society of America, the Pacific Coast Branch of the Palaeontological Society, the Western Society of Naturalists, the Cooper Ornithological Club, the Pacific Slope Branch of the American Association of Economic Entomologists, and the California Academy of Sciences. Sessions of these societies will be held on Thursday, Friday, and Saturday of the period of the convocation.

THE METAL MARKET

METAL PRICES

San Francisco, April 3

Antimony, cents per pound	24
Electrolytic copper, cents per pound	38
Pig lead, cents per pound	9.25—10.25
Platinum, soft and hard metal, per ounce	\$105—111
Quicksilver, per flask of 75 lb.	115
Spelter, cents per pound	13
Tin, cents per pound	50
Zinc-dust, cents per pound	18—20

ORE PRICES

San Francisco, April 3

Antimony, 50% metal, per unit	\$2.00
Chrome, 40% and over, f.o.b. cars California, per ton	18.00—20.00
Magnetite, crude, per ton	8.00—10.00
Tungsten, 60% WO ₃ , per unit	17.50—18.00
Molybdenite, per unit for MoS ₂ contained	40.00
Manganese, 50% (under 35% metal not desired)	29.00
Manganese ore, 40 to 45%, sells f.o.b. Chicago at 58c. per unit with a penalty of 50c. per unit for more than 8% silica.	

EASTERN METAL MARKET

(By wire from New York)

April 3.—Copper is lower and dull. Lead also is quiet at 9.40c. and zinc is stagnant at 10.75c. The price of platinum remains unchanged at \$105 to \$111.

Theorists in regard to currency problems are contemplating the possibility of the re-monetization of silver following the cessation of the European war. The world conflict has had a profound effect on the market for the white metal. In February of this year the price rose to a record level for the past quarter century, and while rapid decline from that figure quickly followed this feat, many authorities are still free in

their predictions that silver will advance to at least one dollar an ounce after the War.

Weakness in Chinese exchange has been a factor in depressing silver prices from their recent high level to below 73c. per oz. The advancing cost in shipping silver abroad, particularly to England, has also had its effect. It now costs about 3¼c. per oz. to export silver from New York to Europe, 1¼c. for freight and 2c. for insurance. The freight rate approximates 2% ad valorem and the insurance 2½% in British bottoms.

The great demand that has existed in India for silver currency during the War did not become really keen until toward the close of 1915. This shows the close link that exists between the demand for currency and high prices for commodities. There is no reason to suppose that recent withdrawals of coin from circulation were other than what is customary, namely, the peasant classes have put by surplus profits against less favorable times. Now that prices have risen so considerably, the margin of profit is larger than usual, and a greater amount of coins is therefore necessary.

LEAD

Lead is quoted in cents per pound, New York delivery.

Eastern Metal Market

New York, March 28.

The entire metal-market is quiet and dull, more pronounced in some cases than others. Buyers seem inclined to await international development next week that are of vital significance before entering on any commitments of consequence. Not much actual business has been done in any metal, but the general tendency has not been toward weakness.

Copper is easier and a little lower, especially for April and second quarter.

Zinc is inactive and still stagnant.

Lead continues steady and fairly firm.

Tin remains strong but large arrivals yesterday have eased the situation.

Spot antimony continues to advance and is hard to obtain at any price.

In the steel market, the relations of the United States Government with the steel makers as to purchases for Government needs, is the absorbing topic. Today an important conference is being held by leading steel men as to the prices at which steel products are to be supplied to the Government, similar to the action last week by the copper producers. It is important to consider that the total consumption for such purposes is not likely to exceed 2% of the steel-making capacity of the country, and hence is not a vital market factor. Prices in general continue to advance, one of \$5 per ton for billets and sheet-bars being important. Pig-iron also is rising, basic iron having gone up not less than \$3 with sales at \$35.

COPPER

The principal topic of conversation the past week in the copper market has been the sale, referred to last week, of 45,000,000 lb. to the United States Government at 16.67c. per lb. or 50% less than the market price. While the action is generally regarded as patriotic, not a few dealers in this district point out that the move was a clever one on the part of at least three large producers. Making this sale at what is regarded as the average price for the last 10 years is believed to have stayed off Government seizure of copper-producing plants. The strike at the Laurel Hill, Long Island, refinery of the Nichols Copper Co. has been settled and deliveries from that source are coming into the market again. In general, business has been slow the past week with little or no interest. Very little new business is appearing. The general easing of the market is not due to the sale to the Government. This is so small with reference to the total output that its effect is inconsequential. The Government's requirements call for 4,000,000 lb. per month and the monthly production is nearly 200,000,000 lb. The quotation yesterday for nearby copper was 35.50c., New York, with second quarter at 34 to 35c., and third quarter at 30 to 31c. The softened tendency is explained as due to large offerings for second quarter. The London quotation for spot electrolytic is unchanged at £151.

LEAD

A leading subject discussed by lead dealers the past week is the action of the copper producers in selling to the Government at the low price they made for delivery over the next 12 months. Lead producers are expected to be asked to do the same, if negotiations are not already under way or completed. That a similar action will result is generally conceded, but the probable price is placed speculatively at various figures. A slump in the market would have taken place before this, it is generally acknowledged, were it not for the fact that producers are generally well sold up and are not under the necessity of going out to solicit orders. Arrivals from the West are better and now sufficient to meet all demands. Spot and March metal is quoted at 9.50c., with 9.25c. asked for April and 9c.

for May and June delivery. The leading interest continues to quote 9c., New York. Spot lead in London is unchanged at £30 10s. per ton.

TIN

The market has been generally dull and uninteresting and not much business has been done. On March 21 about 200 to 300 tons was sold, mostly off-grade, to a Western consumer, but other buying was slow. Thursday and Friday were dull days, with Monday, March 26, not much better, although about 100 tons in all was reported sold on that day. The anxiety manifested lately regarding the steamer *Philadelphian* with 815 tons on board, was relieved by the arrival of that vessel on Tuesday. On the same day the *Eurybates* also made port with 1000 tons. These arrivals have considerably eased the spot-market, which yesterday was 55.87c., having been as high as 56.50c. on Monday. The entire situation is more comfortable. The quantity afloat is now 2436 tons, with 3580 tons reported arrived during March. On Monday more interest was shown with wide inquiry for all deliveries and descriptions, but no business resulted. The month as a whole has been a dull one with sales generally small. The London market continues to advance. Spot Straits was quoted there yesterday at £218 5s. against £214 2s. 6d. a week ago and £201 two weeks ago. Information as to sailings from England are being held up and arrivals here are not given out in full as formerly. It is understood, however, that details of cargoes are to be released once each week.

SPELTER

There is little that can be said about an absolutely stagnant market. Very little business is being done, though about the middle of last week there was a more active market at slightly higher prices. Since then there has been no change and the metal is quoted at 10.75c., New York, for prompt and March, with 10.50c. for April and 10.25c. for second-quarter delivery. Brass makers continue to take no interest and their future wants are uncertain, some of them operating no longer at full capacity. The relation between ore and metal-prices continues at a deadlock. High-grade spelter is selling at 16 to 18c., depending on quality, and fairly large contracts are reported as having been placed. Brass-special is quoted at 11 to 11.25c., St. Louis, for prompt delivery, but is in no demand. Sheet galvanizers were reported yesterday as inquiring for second-quarter metal.

ANTIMONY

The spot metal continues to advance and is quoted nominally at 34 to 35c. per lb. Small sales have been made at these figures, and one sale is noted at 38.50c. The metal is hard to get for immediate delivery. There seems to be a good demand for March shipment, but uncertainties in deliveries make dealers shy of futures. March shipment is quoted at 15.50 to 16.50c. Shipments that used to require only six weeks from the Orient now take often as much as three months. The *Eurybates*, with at least 300 tons, arrived yesterday, but it has probably all been sold.

ALUMINUM

There is little change. Spot metal is a little higher, if anything, at 59 to 60c. for No. 1 virgin, 98 to 99% pure, because a little scarcer in this market.

The personnel of the Pacific Northwest Mining & Metallurgical Experiment Station, Bureau of Mines, at Seattle, is as follows: DORSEY A. LYON, metallurgist and superintendent of station; GEORGE WATKIN EVANS, coal-mining engineer; FRANCIS C. RYAN, electro-metallurgist; HARLAN A. DEPEW, chemist; UNION B. WHITE, clerk.

Book Reviews

THE MINING MANUAL AND MINING YEAR BOOK, FOR 1917. By Walter R. Skinner, 12-mo, pp. 950. Price, \$6.

The annual appearance of this book is always welcomed by those interested in world-wide mining. While published for the use of the public in London, it is invaluable as a book of reference to many outside Great Britain. We have always found it a mine of necessary information. Every year it becomes more accurate and more comprehensive. Besides the record and description of the various mining companies, the 950 pages furnish statistical data, a glossary of mining terms, and a directory of directors, secretaries, and engineers engaged in mining.

CHEMICAL TESTS FOR MINERALS. By Arthur J. Burdick, pp. 93. The Gateway Publishing Co., Beaumont, California. For sale by the MINING AND SCIENTIFIC PRESS. Price, \$1.25, postage 7 cents.

This book is designed to meet the requirements of prospectors who want to be able to recognize the minerals they find while searching among the hills. To the inexperienced eye many valuable minerals bear a close resemblance to others that are of no value. For instance, galena and specular iron often look much alike when disseminated through a rock. It is to help the prospector to determine what the minerals are that he finds that this little work has been published. The book is well arranged and is in such form that almost anyone of intelligence can apply the tests suggested, and thus get the desired results.

ENGLISH AND ENGINEERING. Edited by Frank Aydelotte. 12-mo, pp. 390. Price, \$1.50. Published by the McGraw-Hill Book Company, New York.

This attractive little book is a collection of examples of good writing, intended "to help technical students in expressing themselves better in writing and speaking, and of broadening their outlook on life." The reviewer is so much in sympathy with the purpose of the book that he regrets to criticize it, as he must, for mixing excerpts from such writers as Ruskin, Huxley, Matthew Arnold, Carlyle, Robert Louis Stevenson, and Emerson with the writings of sundry engineers and professors of engineering still alive and altogether lacking the genius of the masters of the art of writing in whose company they are thrust by the well-intentioned editor. The contrast between Huxley and Dr. Mann, between Ruskin and Mr. Harrington, is ludicrous; and the two latter-day engineers should have been spared the comparison.—T. A. R.

METAL STATISTICS FOR 1917. Being the tenth annual edition of this useful little volume, published by *The American Metal Market and Daily Iron and Steel Report*, 81 Fulton street, New York.

Industrial Notes

Information supplied by the manufacturers.

M. B. Myers, formerly assistant to the vice-president of the AMERICAN MANGANESE STEEL Co., has been appointed sales manager for the company.

The WILLIAM POWELL Co. of Cincinnati, Ohio, has issued a handsome tri-color circular, in red, blue, and gold, descriptive of its White-Star valve, that is particularly adapted to working under high pressure and high temperature. The disc, which is regrindable, reversible, and renewable, is made of 'Powellium' white bronze with a melting-point of 2000° F.

The DEISTER CONCENTRATOR Co. has just issued a new bulletin descriptive of the Deister-Overstrom tables. The company has closed a contract with the American Zinc Co. of Tennessee, at Mascot, Tennessee, for 56 of these tables. Pages 14 and 15 of the new bulletin cannot fail to interest all that are interested in concentration. The bulletin will be sent on request.

The TRAYLOR ENGINEERING & MANUFACTURING Co. of Allentown, Pa., has opened branch offices in the West at the following places: Headquarters at Salt Lake City; at Spokane, Washington, for the North-west district, with C. H. Abeling in charge; at El Paso, Texas, for the South-west district, in charge of Robert M. Peabody. The Western business is under the general direction of John A. Traylor, who also represents the Cement Gun Company.

The INGERSOLL-RAND Co., 11 Broadway, New York City, has recently issued two new catalogs on Dry Vacuum Pumps, Form No. 3037 covering the straight-line type and Form No. 3038 on the duplex type. Both machines are equipped with 'Ingersoll-Rogler' valves, are capable of maintaining a high vacuum, and will handle discharge pressures of several pounds. The maximum degree of vacuum possible varies with the different machines, to within 0.6 inches of the barometer. These catalogs will be sent on application.

The Tonopah Bonanza Mining Company of Tonopah has placed an order with the YUBA MANUFACTURING Co., 433 California street, San Francisco, for two turbine-pumps, each pump to have a capacity of 500 G.P.M. against a total head of 1700 ft. Also the Tonopah Great Western Mining Co. of Tonopah, has ordered from the same company a turbine-pump to have a capacity of 550 G.P.M. against a total head of 1200 ft. The Yuba Manufacturing Co. has not completed its bulletin of mine-pumps but has an interesting catalog of general-service pumps that will be mailed on request. The mine-pump bulletin will be out shortly.

The largest electric-hoist under construction for installation in this country is that being built by the NORDBERG MANUFACTURING Co. for the Butte & Superior Copper Co. of Butte, Montana. This hoist is designed for an initial rope-pull of 41,000 lb. and a rope-speed of 2200 ft. per minute when hoisting from a depth of 3000 ft. It has two double-clutched drums, 9 ft. in diameter, and is driven by an 1800-hp. motor, direct-connected to the drum-shaft. When the ultimate depth of 5000 ft. is reached, the drum diameter will be increased to 12 ft. and the hoisting-speed to 3000 ft. per minute and the rope-pull will be increased to 52,000 lb. and a duplicate driving-motor will be added to the opposite end of the drum-shaft.

EDITORIAL

T. A. RICKARD, Editor

WITH an iron production of 40,000,000 tons per annum, and a stock of gold amounting to \$3,075,000,000, the 100,000,000 of people in the United States constitutes a resourceful fighting unit for democratic ideas.

DESPITE the higher cost of aluminum its use as a substitute for zinc in the precipitation of gold and silver from cyanide solutions promises to become important. The advantages, which exceed those of mere regeneration of cyanide, are set forth by Mr. P. H. Crawford elsewhere in this issue. Methods of analysis of aluminum intended for this work are given in a recent article by Mr. J. E. Clennell in the *Engineering and Mining Journal*.

RECENTLY a Japanese engineer called upon us and discussed mining matters. We suggested that among other places of interest he should visit the University of California. He said: "At Stanford." We said emphatically: "No, the State University is at Berkeley." "Oh," he replied, "I thought the great University of California was at Stanford; is not that the university from which Hoover came?" We conceded the point with mixed sentiments. Our visitor was a man of insight; the great university is the one that produces great men. He was right. To that we add that a great university is one that makes public opinion, that has no liking for 'listening leadership,' that is to the front in national and epochal affairs. Stanford has done that too.

THE United States of Colombia is seeking geologists to fill positions on its recently authorized Scientific Commission, now being organized to undertake a geological reconnaissance of that rich republic. Few areas of equal size in the world are so splendidly endowed with mineral resources. In the hands of capable technologists the projected survey should prove stimulative of new and useful enterprises. Climatically many portions of Colombia are undesirable. Unfortunately most of the gold districts are included in the miasmatic areas. This will prevent a wild scramble for positions on the survey, but it must be noted that the great plateau of Bogotá is of unsurpassed salubrity, and the central districts of Santander, the upper Cauca valley, and large parts of Tolima and Cundinamarca are not unsuitable for the men of our race.

ABSORPTION of the Tamarack Mining Company, by the Calumet & Hecla, is only the conversion of control into actual ownership, yet it is an important step. It eliminates one group of stockholders, including some belligerent spirits, and strengthens the position of the

purchasing corporation. The sale has long been contemplated, and arrangements had been made for its consummation last year when a restraining suit was entered by Mr. G. M. Hymans on the ground that the Calumet & Hecla was both vendor and purchaser, which would make the transfer void. It was generally believed that the transaction would not be carried through, but announcement is now made that the Tamarack has been acquired for the sum of \$3,600,000, authorized by a vote of 48,061 shares out of 60,000. The Calumet & Hecla owned 19,400 shares in the company. The Tamarack was incorporated in 1882, and has paid \$9,420,000 in dividends.

INFORMATION concerning the course of events may sometimes help and sometimes hinder the performance of duties that the people may render in the coming conflict, but misinformation can only work harm to all concerned. The times are tense enough without sensationalism. Passions may be aroused by it that need never have been stirred; timidity that may lead to panics injurious to the welfare of the nation may be occasioned. Within these first few days after the acceptance of a state of war the daily press has frequently made clarion announcement of exciting things that later dwindled from three-inch type into six-point paragraphs and then disappeared. We should be protected against canards. It will make for calmer action and superior service if the newspapers be placed under so much official supervision at least as requires that news verified by the constituted authorities be printed with that fact made apparent by an appropriate note at the end of each dispatch.

MILITARY service was a dominant note at the meeting of the Pacific Division of the American Association for the Advancement of Science at Stanford University last week. Each of the co-ordinated societies brought forward its proposals for utilitarian work in the common cause. The seismologists, because of their familiarity with the habits of earthquakes, had been asked by the Ordnance Department to suggest means for detecting the position of distant artillery in action; the physicists were ready with the hope of locating the gun through the medium of the air-wave instead of the earth-tremor. The astronomers are enlisting in the service of Mars, with superior understanding of optics as a first contribution. Dr. W. W. Campbell, director of Lick Observatory, is taking a census of military ideas among the members of his staff for transmission to the authorities. Everywhere the word was passed that men of technical training must start to think for the benefit of the

country, and not to shrink from proposing new ideas for fear that they might in the end prove unsound. One thought leads to the next; the germ of the useful idea may lie in the plan that fails on the initial trial. It was even hinted that the paleontologists be resurrected and interrogated for practical ideas, to which they replied by pointing to their services in the search for oil.

MOLYBDENUM delivered by dirigible balloon is the suggestion of an Alaskan miner who claims to have a twelve-inch vein of solid molybdenite. This metal has had a market-career as uncertain as aeronautics, so the air-route may well fit the case. On the other hand, no doubt exists that the longevity of the large-bore German guns in this war, which at first surprised the world and then led to prompt imitation of German metallurgic practice, has been due to the use of molybdenum. It makes a steel that resists expansion, crystallization, and deformation under the influence of great pressure from high explosives, better than any other alloy that has yet been discovered. Quite apart from other valuable qualities this military use alone will create a demand for molybdenum that must be met—by balloon or otherwise. We believe, however, that the great stores of this material accumulated in certain Eastern warehouses will be more readily available as a first resource than those of the Alaskan tundra.

A NEWS-ITEM states that "the present company has been operating about six months and is now making a scientific search for the lost orebody which so suddenly and mysteriously disappeared about the time the mines were at the zenith of their fame." Much humor is unconscious. No ordinary scientific search will avail to find orebodies of this kind—these that appear so vividly in the reports of imaginative superintendents at a time when the stock-market is sensitive and disappear with the wave of a promoter's wand when the jig is up. Such orebodies remind one of King Arthur's city, which "was built to music, therefore never built at all, and therefore built forever." They cannot be demolished by the blows of fact. They are re-discovered by the method that led to their original disclosure. Even much water cannot extinguish them; they grow under water and assume lordlier dimensions, until in the words of the Johnsonian auctioneer they become "potentialities of wealth beyond the fondest dreams of avarice." Most of us have sought them. Lucky is he that found the boojum and was not grieved to find it only a snark.

NEVADA has yielded to the perennial complaint of the ore-shipper by the enactment of a law intended for his protection against the greedy smelter. It is at best an innocuous statute. It may cost the taxpayers an extra dribble; it will frequently divert the wrath of the shipper from the ore-buyer to the luckless State Assayer, now created to stand between the robber and the robbed. He is to draw a salary of \$3000 per year, and on demand of any shipper is to become his representative to weigh, sample, and assay against the purchaser. For this ser-

vice he will receive 25 cents per ton of ore, plus expenses of travel and maintenance when called to a point at which the deliveries under his supervision are less than 50 tons per diem. It is evident that in either case the cost will be slightly higher than the minimum charges of regular assayers undertaking this branch of service. At first, we apprehend, the State Assayer will be a busy man. When the disappointments of hopeful shippers begin to gather in an angry cloud about his head, he will discover that the law has operated chiefly to protect the buyer against imputation of fraud, while he himself will find his reputation for competency assailed. We extend our condolence in advance to the unfortunate who shall receive the gubernatorial appointment.

FEAR of hostile intent by Mexico is repudiated by that vigorous journalist, Mr. C. W. Barron, in an interview appearing in the *Boston News Bureau*. He sees no sign of Japanese or Teutonic activity that might lead to reprisals against the United States, yet he asks, "Is there any wonder that the people of Mexico have invited support and help from Japan?" We might reply by asking what aid and comfort have the Japanese conceded to the Mexicans? Mr. Barron is clearly of the opinion that it was our duty to finance any *de facto* government that emerged from the revolutionary chaos. Without financial coddling an impecunious government could not expect to prevail against the attacks of opposing factions that distribute the loot of brigandage to their adherents. This is a plausible argument, but when linked with the notion that Japan had performed a service which the United States had evaded, the case is confused. If Mexico turned to Japan, then a community of interest would be created. This might lead to unpleasant consequences in the event of friction between the United States and Mexico. Mr. Barron bestows some not unmerited commendation upon Zapata and his followers, but Zapata openly boasts of receiving supplies from Japan, limited only by his means for making payment. At the same time Carranza has been obtaining military equipment and even machinery for the manufacture of munitions from the same source. In what respect, then, has the government of Mexico found superior friendship in the Japanese? Evidently Japan has played her game so as to win the favor of the Mexican people rather than to sustain the fortunes of a single party. She has most certainly followed a course that, in its practical working, has provoked no national animosity. The intense popularity of the Japanese among all classes in Mexico is as noteworthy as the violent hatred manifested toward American citizens and the American government. In this preference lies potential danger that cannot be overlooked. Had the relations between this country and Japan been characterized by cordiality and co-operation we might lay suspicion aside. On the contrary, there has been persistent friction, and we note with regret that the test case under the law prohibiting Japanese ownership of real estate in California has been forced to an issue at this untimely moment.

Mine Taxation

War brings new needs and new laws. War is supreme. It overthrows the social structures that stand in its way; it creates new ones, built from motives of temporary expedience that sometimes survive their usefulness and encumber the future. In nothing is this influence more likely to be seen than in means for raising revenue. No man will stop to argue over the method of taxation when his country calls for support. It is important that the conception of right methods be so well inculcated in the national mind that the instinctive thought when forced to hurried legislative action shall partake of the spontaneously correct judgment that we denominate common sense. Otherwise we may have a legacy of burdensome principles hampering our future progress. Everything and everybody will be taxed; they must be taxed for our country's good, for the protection of all that we value as Americans. We shall live at constant elbow-touch with the tax-collector. The mines will be taxed. They will be called upon to contribute as never before. The mine-owners will not seek to avoid increased taxation. No man nor corporate group of men can hesitate to offer contribution gladly when it is for protection to the normal rights of citizens. The fundamental object of government is protection to life, property, and the pursuit of happiness. Except for that it would require an overwhelming sense of humor to induce men generally to live in close association with others. Mines have always proved an embarrassment to the law-makers when it came to bases for appraisal and assessment. There is a marked dissimilarity between mining property and real-estate. A piece of land when worked becomes a farm; a mine when worked becomes a hole in the ground. The farmer, as he exhausts the potash and the nitrogen from his land, can put them back; the potash and nitrogen fixed in the tissues of his crops are worth more than in the crude fertilizer that he buys. Thus a farm becomes a site for a permanent chemical industry, utilizing the beneficent gifts of water, air, and sunshine in conjunction with substances that can profitably be added when the soil has become impoverished; but neither sun, nor air, nor water can aid in the re-growth of ore. Once removed it is gone forever, counting by the lives not of individuals, but even of nations and of races. A mine has been called "a wasting asset." That is an essential characteristic of this form of property. It possesses no value, save in the imagination and hope of its owner, until it has been developed. As soon as exploitation begins, though development continue to add to the known life of the deposit, it is being exhausted. Perhaps a wiser view of its relation to the community is to say that it is being benefited. The mine that is being worked is being made good for human uses; the asset disappears, so far as the mine-owner is concerned, but it becomes part of the wealth of the world. It is evident that use is the real value, that productivity is what makes it serve the needs of man. There is no such thing as intrinsic value for a concrete thing; intrinsic value is a term to express the relation

between need and beneficiation, between demand and productive response, and it changes from nation to nation, and from age to age. It is a pleasure to welcome at this critical moment, when manifold schemes of taxation will be developed to meet the needs of warlike preparation, the thoughtful treatise on 'Mine Taxation in the United States,' prepared by Mr. Lewis Emanuel Young, and issued by the University of Illinois as one of its series of Studies in the Social Sciences. It is peculiarly valuable on account of its scholarly analysis of the methods in vogue in the several States of the Union. Mr. Young recognizes that mine taxation in many States has "aimed at something more than the raising of revenue for immediate public needs," to which he does not lend approval. This opens a large subject for discussion. It is important to recognize this sharp cleavage and to talk definitely toward one or the other of these opposite sides of the question. If the mine is to be set apart in an exclusive category to relieve co-ordinate and accessory industry from bearing its proportionate share of the burden of government, it is well that the matter be known and clearly defined. Industry can adjust itself even to oppression if the size of the obligation be fixed and invariable. This is so trite that it should be uttered with an apology to thoughtful men were it not that thoughtful men have not taken hold of the problem and given fixedness to the principles of mine-taxation applicable in the various States. It is rather pitiful to see what a feeble showing of quotable opinion Mr. Young has been able to bring together in his chapter on 'Suggested Methods of Taxation and Reforms.' The clearest note in the whole discussion is struck by Professor E. R. A. Seligman, who says in part: "Let us recognize the fact, once for all, that a system of property taxation

* * * is unsuited to modern economic conditions as the ordinary and principal source of revenue * * *. Let us boldly face the situation and confess that while a classified property tax may constitute the only possible step in advance for those States that are still tied up by a rigid constitution, the scheme is undesirable for those which are more fortunately situated from the constitutional point of view. What then is the remedy? I have no hesitation in answering—the substitution of income for property as the basis for taxation." This is true to the Semitic ideals that hark back even to the laws of Hammurabi. It is the true ideal of socialized man, founded on good utilitarian doctrine. With that we are in agreement. If property were to be accepted as the basis, it must necessarily take into account, as well as may be, the ultimate known value of the mine, which value is ascertainable only after the depletion of the ore reserves and the extinction of the mine as an economic unit. From the property standpoint the formula for the tax-assessor is clearly stated by Mr. Young in these words: "The appraised value of the property may be taken as the capitalized value of the yearly earnings which it is estimated will result from the operation of the property at a yearly output maintained for a fixed term of years at an average profit per ton extending through-

out the whole period, and not providing for any increased output beyond what may be already in sight;" to which we would add that the term 'profit' must mean excess over cost, including depreciation and replacement of plant, besides other items that the mine-owner is likely to overlook as an essential part of the expense of his operation.

Our view inclines us to the principle of the income-tax. Any direct taxation on the real estate itself that is not in its nature a tax upon non-productivity, and therefore operative as a penalty for non-use, is fundamentally opposed to the best interests of a progressive society. The property is of no avail except through its beneficitation. The plan that stimulates to productivity robs no man. It merely takes toll of his thrift, for the protection that it throws around him. By the same token we fail to see the reasonableness of taxation upon plant that is being put to the uses of production. The plant itself is valueless except through its application in response to the needs of the people. It is the product of the plant as well as of the mine that possesses value. On this basis of taxation the ends of social justice would seem to be best ensured.

Nickel

The control of this metal has given deep concern to the Canadian government ever since the promotion of the Canadian Copper Company by S. J. Ritchie in 1886. The known supply of nickel was so limited at that time that the world's annual consumption did not exceed 2,000,000 pounds, and its future importance in the manufacture of armaments and munitions of war was but dimly understood. Notwithstanding this fact the Dominion Parliament displayed remarkable prescience of the possibilities of the industry by insisting at first upon a clause in the charter of incorporation requiring the refining of the metal in Canada. In the end what may be regarded as a gentlemen's agreement was reached, whereby it was understood that the nickel ultimately would be converted into the finished product within the confines of the Dominion, but the mandatory clause was eliminated, apparently in recognition of the fact that the process of refining as then developed was in part a guarded secret of the Orford Copper Company in this country. To have insisted rigidly upon refining at home would have crippled the enterprise at the start. Continuance of the practice of refining the Sudbury nickel in another country has been a sore point for the past three decades, and the nickel question has played a prominent part in Canadian politics. The outbreak of the War accentuated the desire to retain this metal under British control, and the announcement that the merchant submarine 'Deutschland' had secured a cargo of nickel created a still stronger sentiment against the exportation of a commodity so vital in equipment for warfare. The appointment of the Royal Ontario Nickel Commission was the outcome of the agitation. Later, the demand for control of the industry extended from Can-

ada to the mother country. It was hoped that it could be shown that Canada possessed a monopoly of nickel. The Commission refutes this, but indicates that only under the influence of high prices can serious competition be expected. In accordance with this Canadian sentiment the International Nickel Company has voluntarily begun the construction of a refinery at Port Colborne on Lake Erie, as explained in a brief summary of the Commission's report printed on another page of this issue. The International Nickel Company is a New Jersey corporation, organized in 1912 to acquire the Canadian Copper Company, the Anglo-American Iron Company, the Orford Copper Company, together with other nickel-producing concerns in Canada and in New Caledonia. It thus constitutes, in effect, a nickel trust. The visit of Dr. Willet G. Miller, a member of the Royal Commission, to New Caledonia was largely to ascertain how formidable a competition might be expected from that source. Evidently some difference of opinion on this score exists between the officers of the nickel trust and the Canadian experts. Nevertheless, drastic action against the exportation of nickeliferous matte from Canada undoubtedly will be averted by the construction of the great refinery at Port Colborne.

Meanwhile the Imperial government has co-operated with the Dominion government in starting a new domestic nickel enterprise, the British America Nickel Corporation, which owns 17,600 acres of mineral land at Sudbury, including the Murray mine. This corporation has acquired the rights to the Hybinette process, an electrolytic method for refining nickel invented and developed successfully in Norway. The enterprise was promoted originally by Dr. F. S. Pearson, who was drowned on the 'Lusitania' and on his death his associates obtained the aid and support of the British government. In October 1916 Mr. E. P. Mathewson was engaged as general manager, in association with Mr. W. A. Carlyle, who is one of the vice-presidents of the corporation. The association of these two men with this enterprise has evoked the keen interest of the engineering profession. A smelting and refining plant is now under construction at the Murray mine. On the other hand, the intensified development of the Cuban deposits will add to the available resources of non-Canadian nickel, the outlook for extremely large tonnages at Mayari, Moa, and Cubitas being excellent. The known deposits in the United States are of minor importance. The St. Francis mountains in south-east Missouri have long yielded small amounts of nickel in conjunction with lead, and recent discoveries in the same locality are said to promise a considerably augmented output. New deposits are also reported lately from several points in the Appalachians, which are said to bear a resemblance to the Sudbury ores. It is proper that Canada should display keen interest in a commodity that is so valuable a military asset for the British Empire, and it is equally important that earnest efforts should be made in the United States to develop every source of an independent supply of nickel for our own use.

Flotation Litigation

By T. A. RICKARD

The story of American litigation over the flotation patents is interesting and perplexing. The first contest over the validity of the Minerals Separation company's principal patent was caused by James M. Hyde, who, in August 1911, introduced the use of froth-flotation at the mill of the Butte & Superior Copper Company,¹ applying the process successfully to a zinc ore carrying a small amount of lead. On October 3, 1911, suit for infringement of patent 835,120 was brought by Minerals Separation against Mr. Hyde. The trial took place before the U. S. District Court at Butte and there, on July 28, 1913, Judge Bourquin decided that the patent was valid "in respect to all claims in issue."

It will be well to outline the nature of the patent in suit. The first claim says: "The herein-described process of concentrating ores which consists in mixing the powdered ore with water, adding a small proportion of any oily liquid having a preferential affinity for metalliferous matter (amounting to a fraction of one per cent on the ore), agitating the mixture until the oil-coated mineral matter forms into a froth, and separating the froth from the remainder by flotation."

Claim No. 12 states: "The process of concentrating powdered ore which consists in separating the minerals from gangue by coating the minerals with oil in water containing a fraction of one per cent of oil on the ore, agitating the mixture to cause the oil-coated mineral to form a froth, and separating the froth from the remainder of the mixture."

The patentees—H. L. Sulman, H. F. K. Picard, and John Ballot—refer in their specification to the Cattermole patent, No. 777,273, in which mention is made of using "an amount of oil varying from four per cent to six per cent of the weight of metalliferous matter present," and they then proceed to explain:

"We have found that if the proportion of oily substance be considerably reduced—say, to a fraction of one per cent on the ore—granulation ceases to take place, and after vigorous agitation there is a tendency for a part of the oil-coated metalliferous matter to rise to the surface of the pulp in the form of a froth or scum. This tendency is dependent on a number of factors. Thus the water in which the oiling is effected is preferably slightly acidified by adding, say, a fraction of one per cent up to one per cent of sulphuric acid or other mineral acid or acid salt; the effect of this acidity being to prevent gangue from being coated with oily substance, or, in other words, to render the selective action of the oil

more marked; but it is to be understood that the object of using acid in the pulp according to this invention is not to bring about the generation of gas for the purpose of flotation thereby, and the proportion of acid is insufficient to cause chemical action on the metalliferous minerals present. Again, we have discovered that the tendency for the oily substance to disseminate through the pulp and the rapidity with which the metalliferous matter becomes coated is increased if the pulp is warmed. The formation of froth is assisted by the fine pulverization of the ore, and we find that slime mineral most readily generates scum and rises to the surface, while larger particles have less tendency to be included in the froth."

Application for this patent was filed on May 29, 1905, and the rights accruing under the patent start from this date. The patent was granted on November 6, 1906, and the life of the patent, 17 years, is measured from this later date.

Judge Bourquin's decision was sweeping.² It rested largely on a reply to the question whether Froment's British patent No. 12,778, of June 4, 1902, anticipated the patent in suit. On this point the Court expressed itself as follows:

"Froment's [patent] requires several times the quantity of oil that does this in suit, both by examination of the patents and working description and by tests in evidence. Froment crushes the ore in two operations, and deslimes it before treatment, because the slime is too fine to be treated by his process, while the process in suit needs but one crushing operation, and finds slime advantageous and most easily recovered. Froment employs carbonate of lime; the process in suit does not. Froment requires acid, and in greater quantity and for a different function than does the process in suit, which latter may or may not use acid. Both may use heat, and both require agitation—Froment agitation only to disseminate the oil, the process in suit for that purpose and also to aerate. Froment's result is by flotation by gas generated *in situ*; this in suit is by flotation by air introduced by vigorous agitation. Froment's product is like unto a magma, a spongy, pasty mass of oil and metallic particles, and more or less gas bubbles, while this in suit is a froth of oil and metallic particles and air-bubbles. Froment's requires oil in such quantity that he deems it worthy of recovery from the concentrate, so far as it can be; this in suit so little oil it disappears, is not sensible to sight or touch upon the concentrate but only to analysis. In Froment's it would seem that the metallic particles are floated like the bas-

¹This company did not produce copper, but zinc, lead, and silver. In 1916 the name was changed to Butte & Superior Mining Company.

²For full text of this decision see M. & S. P., August 16, 1913.

ket of a balloon, while in this like the very envelope of a balloon. Froment's is costly, while this is cheap. And from the evidence it would seem that Froment's process would fail in practical operation, while this in suit has succeeded. In Froment's he oils the metallic particles by agitation; then, when the mixture is quiescent, generates gas therein by quick reaction, followed by immediate and direct rising of the gas bubbles to the surface in which they may come into contact with but few metallic particles. In this in suit vigorous agitation of the mixture beats great and excess volumes of air therein, likely bringing the ultimate air bubbles into repeated contact with many metallic particles. The action of the gas in Froment's is almost explosive in nature. He speaks of proportion of carbonate of lime to be sought as, in his test-tube example, the reaction may be so sudden and violent as to project the metallic particles out of the tube. Froment's gas bubbles, quick formed and quick rising it may be, arrive at the surface with expansion still in progress. These or analogous reasons may account for Froment's magma breaking gas bubbles and fragile evanescent froth in so far as his result is like unto froth, and also may account for the process in suit's strong and lasting froth."

On appeal to the Ninth Circuit in San Francisco the decision of the lower court was reversed, on May 4, 1914. The opinion of the Court of Appeals, pronounced by Judge Gilbert, stated that "the fact that the appellees use a smaller quantity of oil than was used in the prior art is not of itself, and is not claimed by them to be, sufficient to distinguish their process so as to render it patentable." This Court held that "the agitating of the mixture to cause the oily-coated mineral to form a froth" was "clearly anticipated by the prior art." It is noteworthy that the Examiner of Patents rejected claim No. 12 "in view of 763,260, Cattermole, June 21, 1904; or 793,808, Sulman et al, July 4, 1905, . . . as expressing merely a difference of degree thereover as to the proportion of oily matter employed." Thus the Examiner refused to allow patentability on the mere use of a small percentage of oil. The claim thus cancelled, not the No. 12 of the final patent, quoted above, was the only one that was based exclusively on the use of a fraction of 1% of oil, without reference to a particular kind of agitation or a particular kind of froth. The Appellate Court took cognizance of this interesting disclosure, for Judge Gilbert said:³

"We hold that to sustain the appellees' patent would be to give to the owners thereof a monopoly of that which others had discovered. What they claim to be the new and useful feature of their invention, as stated by their counsel, is 'agitating the mixture to cause the oily-coated mineral to form a froth.' As we have seen, that feature was clearly anticipated by the prior art, and when the elements of the appellees' claims are read one by one it will be found that each step in their process is fully described in more than one of the patents of the prior art, with the single exception of the reduced quantity of oil

which they use. The patentees of the appellees' patent made a valuable contribution to the art in discovering the smallest quantity of oil which would produce the desired result. In doing so they pursued the course which all skilful metallurgists would be expected to pursue. They made a series of experiments to determine how small a quantity of oil could be used successfully. They found, as all must find who apply the oil flotation process, that certain oils are adapted to use with certain ores, and that a larger quantity of oil is necessary for one kind of ore than for another. The appellees admit that for some ores they use four times as much oil as for others. Their discovery that a small fraction of one per cent of oil is sufficient to produce flotation of the metalliferous matter cannot, as we have seen, be made by itself or in a combination the subject of a patent. The appellees cannot take from others the right to use oil economically. This was evidently the ruling of the Patent Office on their application for a patent. One of their claims in the original application was 'the process of concentrating powdered ore, which consists in separating minerals from gangue by coating the minerals with oil in water containing a fraction of one per cent of oil on the ore, and recovering the oil-coated minerals.' This was rejected in view of the Cattermole patent 'as expressing merely a difference of degree thereover as to the proportion of oily matter employed.' Counsel for appellees admit that the claim was properly rejected for the reason that it leaves out the agitation and froth, and say 'our invention is something else than the mere reduction of oil.'"

Thereupon Minerals Separation obtained a hearing before the Supreme Court of the United States on a writ of certiorari. The case was argued in October 1916. The court expressed its opinion through Mr. Justice Clark on December 11, 1916. It was laid down that the patent was valid on three counts, (1) the use of a 'critical' and minute proportion of oil, (2) the use of a particular kind of agitation, namely "by beating air into the mass," and (3) the production of a "peculiarly coherent and persistent" kind of froth. The most important parts of the opinion are to be found in three paragraphs.⁴ The first defines the patent:

"The process of the patent in suit, as described and practiced, consists in the use of an amount of oil which is 'critical,' and minute as compared with the amount used in prior processes 'amounting to a fraction of one per cent on the ore,' and in so impregnating with air the mass of ore and water used, by agitation—"by beating air into the mass"—as to cause to rise to the surface of the mass, or pulp, a froth, peculiarly coherent and persistent in character, which is composed of air bubbles with only a trace of oil in them, which carry in mechanical suspension a very high percentage of the metal and metalliferous particles of ore which were contained in the mass of crushed ore subjected to treatment. This froth can be removed and the metal recovered by processes with which the patent is not concerned."

³For the full text of this decision see M. & S. P., May 9, 1914.

⁴For full text see M. & S. P., December 30, 1916.

"It is obvious that the process of the patent in suit, as we have described it, is not of the Metal Sinking class, and while it may, in terms, be described as a Surface Flotation process, yet it differs so essentially from all prior processes in its character, in its simplicity of operation and in the resulting concentration, that we are persuaded that it constitutes a new and patentable discovery."

The third declares the validity of the patent, but restricts its application.

"While we thus find in favor of the validity of the patent, we cannot agree with the District Court in regarding it valid as to all of the claims in suit. As we have pointed out in this opinion there were many investigators at work in this field to which the process in suit relates when the patentees came into it, and it was while engaged in study of prior kindred processes that their discovery was made. While the evidence in the case makes it clear that they discovered the final step which converted experiment into solution, 'turned failure into success' (*The Barbed Wire Patent*, 143 U. S. 275), yet the investigations preceding were so informing that this final step was not a long one and the patent must be confined to the results obtained by the use of oil within the proportions often described in the testimony and in the claims of the patent as 'critical proportions' 'amounting to a fraction of one per cent on the ore,' and therefore the decree of this court will be that the patent is valid as to claims No. 1, 2, 3, 5, 6, 7, and 12, and that the defendant infringed these claims, but that it is invalid as to claims 9, 10, and 11. Claims No. 4, 8, and 13 were not considered in the decree of the two lower courts and are not in issue in this proceeding."

Meanwhile a number of Western mining companies had begun to use flotation. One of them was the Miami Copper Company, in Arizona. On October 10, 1914, suit was brought by Minerals Separation for infringement of patent No. 835,120 and also of No. 962,678 and 1,099,699. The first trial took place in the District Court at Wilmington, Delaware, and the decision, by Judge Bradford, was pronounced on September 30, 1916.⁵

In this case the issue differed from that involved in the previous litigation. Hyde had denied, not infringement, but the validity of patent 835,120. The Miami company denied infringement, claiming that it was using a method similar to that described in a patent of earlier date, namely No. 793,808. Judge Bradford accepted this contention. He said:

"The evidence shows that the defendant in its concentration of ore in its pneumatic flotation plant employs the process of patent No. 793,808, of July 4, 1905, to Sulman & Picard, hereinbefore discussed, as modified by the use of certain apparatus substantially the same as a portion of the apparatus, the operation of which is described in the above-mentioned Callow patent," namely, No. 1,104,755 of July 21, 1914, to John M. Callow. He de-

cided that the Froment patent was not an anticipation because "it does not appear that there was present in the Froment process the very minute quantity of oil of the first patent in suit."

The essential part of the Wilmington decision is that the diminution of oil to less than 1% of the weight of the ore is patentable. Judge Bradford said:

"On the whole I am satisfied that the first patent in suit must be sustained as to claims 1 and 12, but not as to claim 9. The two former are definite, specifying and limiting the amount of oil to be used; claim 1 mentioning 'a small proportion * * * amounting to a fraction of one per cent on the ore,' and claim 12 'a fraction of one per cent of oil on the ore.' Claim 9 mentions 'a small quantity of oil.' This is so indefinite as to render the claim void, unless on consideration of the patent as a whole the claim can by construction be limited to the use of oil amounting to only a fraction of one per cent. The patentability of the process of the first patent in suit resides in the use of oil in the extremely minute proportion disclosed in the descriptive portion of the patent to effect separation of froth with its metallic particles from the remainder of the mixture by flotation. The amount there disclosed is not in excess of 'a fraction of one per cent on the ore' and may be only one-tenth of one per cent on the ore, or even less. If, then, by construction claim 9 should be so limited as to be restricted to the use of oil amounting to only a fraction of one per cent on the ore, that claim is in substance, though not in exact phraseology, the same as claim 1 for the reason that in any event from the nature of the invention it would be necessary to read 'by flotation' into claim 9, if in other respects valid. But a limitation by construction producing such a result is inadmissible. It is suggested by one of the plaintiff's counsel in his consideration of claim 9, that one for the purpose of securing immunity from the consequences of infringement might use an oil useful in the process, and add to it an oil not useful as applied to his particular ore, and, on being sued for infringement contend, 'I am using 1.1% of oil. I do not infringe. I am using more than a fraction of 1% of oil.' But the existence of this possibility does not, I think, warrant such a construction of claim 9 as is urged; for the disclosure of the patent does not extend to the use of 1.1% of oil, but is limited to a fraction of 1%."

In regard to the second patent in suit, No. 962,678, of June 28, 1910, to Sulman, Greenway, and Higgins, the Court quotes part of the description in the patent:

"According to this invention the crushed ore is mixed with water containing in solution a small percentage of a mineral-frothing agent (that is of one or more organic substances which enable metallic sulphides to float under conditions hereinafter specified) and containing also a small percentage of a suitable acid such as sulphuric acid, and the mixture is thoroughly agitated; a gas is liberated in, generated in, or effectively introduced into the mixture and the ore particles come in contact with the gas and the result is that metallic sulphide particles

⁵For full text of this decision see M. & S. P., October 14 and 21, 1916.

float to the surface in the form of a froth or scum, and can thereafter be separated by any well-known means. Among the organic substances which in solution we have found suitable for use as mineral-frothing agents with certain ores are amyl acetate and other esters; phenol and its homologues; benzoic, valerianic, and lactic acids; acetones and other ketones such as camphor. In some cases a mixture of two such mineral-frothing agents gives a better result than a single agent. * * * The present process differs from the two before mentioned types and from other known concentration processes by the introduction into the acidified ore pulp of a small quantity of a mineral-frothing agent, that is, an organic compound in solution of the kind above referred to and by the fact that the metalliferous particles are brought to the surface in the form of a froth or scum not by mechanical means but by the attachment of air or other gas bubbles thereto. In the frothing process hitherto known the substance used to secure the formation of a mineral-bearing froth has been oil or an oily liquid immiscible with water. According to this invention the mineral-frothing agent consists of an organic compound contained in solution in the acidified water."

The Court then proceeds to say:

"It will be observed that no one of the claims of the second patent in suit requires as an element an oily substance or liquid, as is essential in the process of the first patent in suit, and all of the claims relied on require the introduction into the mixture of 'a small quantity' of a 'mineral frothing agent' or an 'organic mineral frothing agent.' The amount of the mineral frothing agent employed in the process is not confined to a fraction of one per cent on the ore, but must be a small quantity, evidently to be determined by the metallurgical engineer conducting or superintending the operation according to the requirements of the different ores. The novelty of this invention is to be found, not in any restriction of the amount of the mineral frothing agent to any stated proportion, for there is none, but in the fact that a mineral frothing agent as the means of separating the metallic particles from the gangue is substituted for the oil, fatty acid, or other oily substance essential to the process of the first patent in suit. Such substitution has produced successful results, and, I think, involved invention. Frothing agents had theretofore been used in ore concentration, but not in the absence of an oily ingredient. Even were the grounds on which the validity of the patent can be sustained less clear, it should have the benefit of the presumption of validity arising from the grant of letters. That the defendant has infringed the claims in suit of the second patent is established by the evidence."

The third patent, No. 1,099,699, was not sustained and need not be discussed.

The most remarkable feature of Judge Bradford's opinion is that he states flatly that the Miami is using the process of patent 793,808 yet he holds that the company has infringed patent 835,120, the numbers of these patents indicating their relative age.

An analysis of the decisions up to date shows that

three courts out of four have sustained the validity of patent 835,120 but the reasons have been dissimilar and even contradictory. For the sake of brevity, I shall refer to the courts by the cities in which the issue was tried.

Butte said that Froment did not anticipate Sulman et al.

San Francisco said that he, and others, did do so. This court refused to consider the mere diminution in the proportion of oil as a subject for patent.

The Examiner of Patents had decided likewise.

Washington granted validity on account of limitation of oil, peculiar agitation, and peculiar froth. This court decided that Froment's process "was little more than a laboratory experiment" and did not anticipate the workable process described in 835,120.

Wilmington granted validity on account of the specification of critical proportion of oil, and adverse the one claim that did not specify that limitation.

Moreover, the Supreme Court differs with everyone that has passed on patent 835,120. It holds the Patent Office wrong for having granted indefinite claims, it holds the Butte court wrong in deciding that such indefinite claims were valid, it holds the San Francisco court wrong for invalidating the whole patent, by inference it holds the Wilmington court wrong for basing patentability on a small proportion of oil alone.

It is a curious fact that the practicability of producing an effective froth by means of more than 1% of oil was not tried on a working scale before these suits were started. Such experimental demonstrations as were made, out of court or before the judges, were apparently unconvincing, for the sufficient reason, I believe, that the minimum proportion was considered best even by the defendants, but as soon as the Supreme Court had given its opinion and placed so much emphasis on the 'critical' proportion, the use of more than 1% of oil was applied successfully on a scale of over 1000 tons per day in the mills of the Utah Copper and Butte & Superior companies, in Utah and Montana, respectively. The 'critical' point was proved fallacious early in 1917.

An appeal from the Wilmington decision was taken promptly by the Miami company to the Court of Appeals for the Third Circuit, at Philadelphia, where the case was heard in February 1917. As was to have been anticipated, the appellees made the most of the Supreme Court's decision in the Hyde case, in so far as it defined and limited the scope of patent 835,120. Counsel argued that the Miami had not infringed because its metallurgical operations differed radically from those described in the Supreme Court's decision, both in the kind of aeration employed and in the character of the froth produced. Whereas Hyde, and Minerals Separation, used mechanical means for causing violent agitation and producing the 'cauliflower' froth, as Mr. Ballot had termed it, they, the Miami company, used a Callow cell, an inclined trough having a porous bottom through which compressed air at a low pressure was admitted, producing a froth without the aid of mechanical agitation, and the froth thus formed was described as thin,

tender, and evanescent. This froth broke and disappeared as soon as the supply of air was withdrawn, while the froth produced by beating air into the pulp would last for days. While the Miami used less than 1% of oil, it did not employ the two other elements essential to patent 835,120, namely the violent mechanical agitation and the formation of a peculiarly coherent and persistent froth. It was argued that a patent claim for a combination of any three elements, such as those specified by the Supreme Court in patent 835,120, created a monopoly only in the use of a process in which all three of the stated elements were used. No monopoly was secured of any one of the elements used singly and apart from the others. Therefore, there was nothing in the Supreme Court's decision giving Minerals Separation a monopoly of the use of a fraction of oil *per se*; on the contrary, the Supreme Court stated that the patent derived its validity from the three factors taken together. So the Miami company contended that it had a perfect right to use any quantity of oil, however minute, provided it used the oil in a process that did not include the violent agitation and the persistent froth characteristic of the Minerals Separation process. Whereupon the patentees had to repudiate the limitations specified by the Supreme Court and depart from the contention that they had made in the Hyde case concerning the special and remarkable character of the froth produced by their process. In the District Court the great difference between the two kinds of froth, one due to beating air into the pulp during violent mixing and the other to the simple introduction of compressed air through a porous bottom, had been emphasized heavily and the statement had been repeated that a shovel had been seen to rest on the froth of patent 835,120, whereas even a match would sink through the kind of froth made at Miami. In the appeal at Philadelphia another tack had to be taken, so counsel for Minerals Separation, in their reply brief, stated:

"With respect to the character of the froth, there can be no serious contention. Before the discovery of these patentees nothing in the nature of froth (a collection of bubbles on the surface) remained long enough to permit recovery of the metal. By reason of the discovery of these patentees a froth was produced, composed of 'modified' air bubbles, coherent and persistent enough to permit of recovery of the metal. That was the unique thing—the peculiarity adverted to by the Supreme Court. In defendant's practice the froth produced by it is similarly composed of 'modified' air bubbles, and so is coherent and persistent enough to permit of recovery of the metal. There is no point and nothing of importance in the degree of coherency or persistency beyond and in excess of that required for the recovery of the valuable metal."

Some reference to the previous litigation in England and Australia may be made, although it is now only of secondary importance. It is vital to the proper understanding of the patent litigation as a whole to recognize the fact that the decisions in the British and Australian

cases did not establish the validity of the British equivalent of U. S. patent 835,120. That issue was not before those courts; indeed, the prior art, except as it had a bearing on the validity of the Elmore bulk-oil patents, was not under consideration. Moreover, it was the Elmore bulk-oil patent of 1898 and not the vacuum-air patent of 1904 that was at stake. The question before the British and Australian courts was the validity of Frank Elmore's British patent No. 21,948 of 1898 and Stanley Elmore's British patent No. 6519 of 1901, the first the principal bulk-oil patent and the second a modification specifying the use of acid. No account was taken of the patents issued between the dates of these Elmore patents and the date of the Minerals Separation patent of 1905, nor was the question of how such intervening patents would affect the validity of 835,120 considered. To establish the fact that Elmore's bulk-oil patent is not valid or that the M. S. process is not the Elmore process does not prove anything with regard to the validity of the M. S. patent. That question was not before the British courts and it is remarkable therefore that these cases should have been cited at all in the American courts. The effect of the citation has been only confusing.

Most of the English suits were between Minerals Separation and the Elmores, or the company with which they were identified. Personal quarrels and charges of bad faith were made in *Sulman & Picard v. Wolf*, in 1905, and in *Ore Concentration Company [Elmores] v. Webster and others [the Minerals Separation group]* in 1908, but the two cases involving basic patent-rights were both brought by the Elmores against Minerals Separation.

In the first case, ended in 1909, *British Ore Concentration Syndicate Ltd. and Alexander Stanley Elmore v. Minerals Separation, Ltd.*, the principal issue was the validity of the Elmore bulk-oil patents of 1898 and 1901 against the Minerals Separation process as described in British patent No. 7803, the equivalent of U. S. 835,120. The Court (Mr. Justice Neville) gave judgment against the Elmores and decided that:

(1) The selective action of oil for sulphides was known before Elmore obtained his patents, and was disclosed in prior expired patents.

(2) Elmore's patent was for a process wherein a large quantity of oil was used, sufficient to carry all the sulphides to the surface by the buoyancy of the oil.

(3) The Minerals Separation process used only an infinitesimal amount of oil for the purpose of attaching air-bubbles to the sulphides, causing them to float by the buoyancy of the air-bubbles, and did not infringe F. E. Elmore's patent.

(4) The use of acid in oil processes was known before A. S. Elmore obtained his patents and was disclosed in prior expired patents, therefore, Elmore's patent was not infringed by Minerals Separation.

The plaintiff appealed and the decision of the court was reversed, it being held that Minerals Separation was infringing the 1901 patent; involving the use of acid with oil. The Court of Appeal found that

(1) The first Elmore patent was not anticipated by previous expired patents [such as those of Robson and Everson].

(2) If Minerals Separation used a thin oil they would not infringe Elmore [who used a thick oil; so also Minerals Separation used a thicker oil (oleic acid) than is now customary in the United States].

(3) The second Elmore patent [that of A. S. Elmore of 1901] was not anticipated by previous expired patents [such as Everson's, in which acidulation is mentioned].

(4) Minerals Separation infringed the second patent by using acid.

An appeal was then taken to the House of Lords and on November 16, 1909, the judgment of the Court of Appeals was reversed, that of the trial court being upheld.

The Lord Chancellor (the Earl of Loreburn) said that the Frank Elmore patent of 1898 need not be discussed, because it had no place in the controversy, "into which it has nevertheless been introduced with no other result than to confuse the issue." He held that the Stanley Elmore patent of 1901 was "framed with great subtlety, being partly narrative, partly claim" and "designed in order that the claim might be expanded or contracted as occasion might require in the interest of the patentee"; that the only definite claim was for acidulation, and that this claim was anticipated by Everson; therefore the patent could not be sustained.

The Earl of Halsbury was of the opinion that the inventions of Elmore and Minerals Separation were "essentially different," the one being dependent on "the selective action of oil, the other upon surface tension"; that acidulation had been "invented and patented" before the date of Stanley Elmore's patent, and that this patent was so ambiguously stated that it should be held bad.

Lord Atkinson likewise described the specification of the patent as "framed, somewhat craftily, in terms of studied vagueness and ambiguity"; he held that it could not claim "the mere addition of acid in small quantities to a mixture of ore, water, and a relatively infinitesimal quantity of oil reduced to a 'freely flowing pulp'." If the patent was for the addition of a small quantity of acid and a relatively large quantity of oil to a mixture of ore and water, where the oil, in accordance with some obscure law of affinity, seized upon the minute particles of ore in preference to the earthy particles, and, by the buoyancy of oil, floated them to the surface, then the Minerals Separation did not infringe this process, because their process was one where they made use of the known selective action of oil, yet the oil was used in relatively small quantities, and the metallic particles were only coated with a thin film of it, and the lifting force was found, not in the buoyancy of the oil, but in the natural buoyancy of the air-bubbles, which, introduced into the mass by violent agitation, envelop or become attached to the oiled mineral particles and raise them to the surface.

Lord Shaw of Dunfermline said: "It has already

been determined that the use of thin oil instead of thick imports no infringement of the 1898 patent, nor do I see my way to hold that there has been any contravention of the 1901 patent by the application of the acid to a mixture in which the oil has been reduced from bulk, to the merest fraction, and especially when froth instead of oil has been secured, along with the law of capillarity or surface tension, as the main floating and separating agent." He held that the processes were essentially different and that there was no infringement.

Lord Ashbourne concurred with the decision of their lordships, thus making the judgment of the Court unanimous.

Meanwhile, in 1910, the Elmores had brought suit against the Sulphide Corporation, a licensee of Minerals Separation, operating at Broken Hill. The issue was tried in Australia with a result adverse to the Elmores, who then appealed to the Judicial Committee of the Privy Council, which heard the case in November 1913 and gave a decision on March 6, 1914. This decision confirmed the lower court and was in accord with that of the House of Lords; the Judicial Committee found that the Everson patent did not anticipate the Elmore acid-oil patent, but, on the other hand, that the Minerals Separation process was not an infringement of the Elmore patent, because it relied on surface-tension, and not oil, for the flotation effect.

I quote two of the decisive paragraphs in this decision of the Privy Council:

"The Appellants place considerable importance on the second form of apparatus described in the patent. In this apparatus a thin stream of oil is thoroughly mixed with the pulp, and the oil 'by its selective action coats or absorbs the metallic particles, sulphides, tellurides, and the like.' The whole mixture then flows over a weir and down an incline over a number of wave-like steps or baffles by which the stream of pulp and oil globules is thrown against an oiled apron continuously moving in the opposite direction. Separation is effected by the oiled surface of the apron taking up most of the oil globules and by also picking up from the pulp such particles of metallic substances as have escaped oil selection in the mixer. The patentee distinctly draws attention to the fact that separation in this apparatus does not depend upon the buoyancy of the oil, and that consequently tar, heavy residuum oils, and other like substances of a greater gravity than water may be employed as the selective agent. The question arises whether the selective action of the oil or tar when the separation is effected by the second apparatus differs from the selective action of oil when the separation is effected in the first apparatus. The answer is in the negative. The 'coating or absorbing' described in connection with the second apparatus is not different in character from the entrapping described in the first apparatus. The 'oil globules' hold and carry the metallic particles and are taken up by the oiled surface of the apron, which also picks up from the pulp such particles of metallic substances as have escaped selection by the oil in the mixer,

that is to say, such particles as have not been coated and carried in the 'oil globules.'

"Apart from any question of theory, the Respondents use oil in their process under conditions which make it almost impossible to entrap or coat and hold the metallic particles by the selective agency of oil. The Respondents use a thin oil at a temperature of 120°F., the quantity is minute, not more than 2 or 3 pounds to a ton of ore, or about 2 or 3 pints of oil to 10,000 pints of water; the resulting concentrate is practically free from oil, and no mechanical contrivance to separate the oil from the metallic particles is required or used; the residue of the first concentration is further treated without any further addition of oil. There is no doubt a difference in the views of the respective experts whose standing and experience entitle them to great weight and authority, but in deciding between these views their Lordships accept the evidence of Professor Pollock to be found in questions 5780 and the following questions. This evidence may be summarized as follows: Professor Pollock is referred to his earlier evidence, and states that he does not think that the small quantity of oil introduced in the defendants' process necessarily performs any other function than permanency in the froth and extremely minute emulsion. He allows that there may be oil in excess, and that some of the particles may get oiled, but states that this is entirely and absolutely unessential. He does not, however, think that more than the necessary quantity of oil is introduced to effect concentration, but that having regard to the nature of the problem it is a matter of conjecture, and exact calculation is not possible. Finally, he reiterates his opinion that the defendants' process can be accounted for without assuming selection of the metallic particles by oil. Applying this evidence, their Lordships find that the Respondents do not either directly or indirectly use the invention claimed by the Appellants, but a process essentially distinct, and that there is no infringement."

Throughout these British and Australian litigations the validity of the bulk-oil patents, of 1898 and 1901, and not of the vacuum patent, of 1904, was at stake. It is a curious fact that whereas the Elmore vacuum method depends upon surface-tension and the use of air quite as much as the Minerals Separation method, it was not cited in the litigation and it was ignored by the courts. It is also curious that during the six years of litigation in the United States the Elmore vacuum patent was not used to attack the validity of 835,120, although this patent of Minerals Separation was taken out in England on April 12, 1905, as compared with Elmore's vacuum patent of August 16, 1904. It may be asked, why did not the Miami company fall back on this defence and use Elmore to fight the Minerals Separation? The answer is the fear to establish another patent monopoly, possibly no more pleasant than the one already on the ground. However, in May 1915, after the Miami suit had been heard at Wilmington, the Elmore vacuum patents were purchased for \$50,000 by a syndicate headed by Messrs. D. C. Jackling and J. Parke Channing, representing the

Utah, Miami, and other important copper-mining companies in the United States. It is possible that the possession of these Elmore patents may prove an interesting factor in later litigation, but it is more likely that the use of oil will be discarded before the litigation is ended.

The decision of the Court of Appeals at Philadelphia is expected at any moment. Meanwhile it is to be noted that after Minerals Separation won the preliminary decision in the Hyde case at Butte they brought suit against the Butte & Superior company and moved for a preliminary injunction. This was in the autumn of 1913. The Butte & Superior case was brought before the same court as that in which the Hyde case was first tried, and this court, at Butte, ruled that no injunction would be issued if the Butte & Superior company would file a bond and also file monthly reports of its flotation operations with the Clerk of the Court. This condition was fulfilled. No injunction was issued and the case has rested in *statu quo* up to the present. The trial begins on April 16.

Volatilization Method for Lead Ores

At the metallurgical research branch of the Utah station of the Bureau of Mines, A. E. Wells has obtained interesting results in experiments on low-grade lead ores which had failed to respond to treatment by flotation or leaching. Mixing these ores with sodium chloride, and heating to temperatures of about 800°C., high extractions of lead were obtained, irrespective of the character of the gangue. The lead volatilizes as a chloride, and the silver and gold also volatilize. The volatile products are precipitated from the fume by the Cottrell precipitator. The precipitated lead chloride, after admixture with lime and a reducing agent, is heated to redness, when the metallic lead settles out, and a slag of calcium chloride is formed. Calcium chloride is suitable as a substitute for the sodium chloride in the first operation. From 50 to 75% of the chlorine is recovered in this manner. The process offers the advantage of producing lead bullion from either oxide or sulphide ores in places where water is insufficient for milling purposes.

WHEN BARRING DOWN, especially in a stope where there is a lot of bar work to be done, it is a good idea to first see that the floor is good and clean. See that there are no tools or loose lagging to trip and fall over. One may have to make a quick jump backward or sideways to avoid a falling rock, for no one can tell which way a rock is going to bounce when it hits a cap or girt. Watch the bar, for it is surprising the way a rock will slide down a bar and give the holder a cut or bruise. Never stand behind a man using a bar, but if possible stand where it is possible to watch the ground and observe a seam or crack opening up that he failed to see. Try to avoid barring over a cap or girt, for a rock may strike the end of the bar and a broken arm or jawbone may be the result.—*The Anode*.

Tank Earthwork

By H. N. HERRICK

The formulas on the opposite page are for use in calculating the quantities of earth-work involved in the preparation of sites for large steel tanks. By the use of these formulas, all calculations may be made directly in the field-book used in setting grade-stakes, without drafting-instruments or planimeter. This is of special advantage when several sites are to be compared in the field to determine which will require the least grading.

Special formulas are given for grades 125 feet in diameter, usually used for 55,000-bbl. oil-tanks of 114 ft. 6 in. diameter, and for grades 105 ft. diam. adapted to the 37,500-bbl. tanks in common use in the oil business. A general formula is given for smaller grades. While the calculation appears rather complicated at first glance, its simplicity will be apparent on comparing the example worked out for a 125-ft. grade with a similar computation by some of the other common methods.

The derivation of these formulas is too tedious to be given in detail, but it may be outlined as follows:

(1) The cylindrical figure whose horizontal projection

is the base of the grade is made up of a number of prisms, the areas of whose horizontal bases are known from the conditions assumed, and whose vertical edges are the 'cuts.' The volumes of these prisms are calculated, the cuts being represented by the letters shown on the diagram, added together, and reduced to cubic yards.

(2) The ring, of varying triangular section, outside of the cylinder, is treated as follows: The area of the triangular section at each 30° line is expressed in terms of the cut at the edge of the base and the elevation of the slope-stake (set where the excavation meets the natural surface), the slope of the bank being given. The distance from the centre of the grade to the centre of gravity of this triangular area is found in terms of the same quantities and the radius of the grade, and the volume generated by swinging the triangle through 30° calculated according to Guldin's principle. The volumes thus found are added together, reduced to cubic yards, and added to the volume found in (1).

The formulas apply equally well to a grade that is to be made entirely in fill, by substituting "fill" for "cut" throughout. Tank-grades should never be built in both cut and fill, for obvious reasons.

Flotation at the Suan Concession

In December last the total concentrate recovered in the Suan mill of the Seoul Mining Co. in Korea had a value of \$20,791, of which \$16,975 was recovered by flotation. The ore presents unique features that call for a high degree of technical skill in treatment. The gold is associated with copper sulphides, the sulph-arsenide (mispickel) and arsenides of iron. The flotation plant takes the tailing from the table-concentrators. During the month the flotation plant was in operation 94.4% of the total time, and treated 4425 tons of pulp averaging 1.85 dwt. gold and 0.70% copper. The tailing from the flotation cells assayed 1.07 dwt. gold per ton and 0.08% copper, while the grade of the concentrate was maintained at 34.25 dwt. gold and 26.41% copper. The recovery effected by flotation alone, based on the assay-value of the concentrator-tailing treated, was 89.1% of the copper and 43.8% of the gold. The latter points to the difficulty experienced in floating the arsenides, which are in a state of excessively fine comminution. Furthermore, the arsenides respond less kindly to flotation. The pulp sent to the flotation-cells contains only 9.5% coarser than 100-mesh. It is diluted in the ratio of 3.3 water to

Lime is found essential and is employed at the rate of 2.82 lb. per ton of ore. The function of the lime is to produce flocculation of the slime, which in this case has proved a necessary condition for success. On the ore from the neighboring Tul Mi Chung, belonging to the same company, the use of lime is prohibitory, and caustic soda, a deflocculent, is used in the proportion of 2.49 lb. per ton of ore, combined with 0.49 lb. eucalyptus oil and 0.01 lb. red engine-oil as floatative agents. The caustic soda also performs the function of a floatative assistant in this case. Carbonate of soda (soda-ash) would normally be preferred on account of its cheapness, but under existing war conditions the output of the soda-ash factories in the United States and England is under contract more than a year ahead. Caustic is produced electrically at a few plants, and is more readily available. At the Suan mill careful tests have been made to determine the relative efficiency of beating in air by agitation with a Minerals Separation machine and introducing compressed air in a Callow apparatus. Contrary to the experience in some of the largest copper-concentrating plants in the United States, mechanical agitation has proved advantageous, as revealed by parallel tests extending over a month, as shown by the averages for the period, given in the table below.

	—Heads—		—Concentrate—		—Tailing—		—Recovery—	
	Gold, Dwt.	Copper, %	Gold, Dwt.	Copper, %	Gold, Dwt.	Copper, %	Gold, Dwt.	Copper, %
Air	1.6	0.59	12.7	13.2	1.3	0.10	18.75	83.05
Mechanical	1.8	0.64	20.8	13.9	1.1	0.07	47.6	89.05

1 of solid matter. The flotation reagents used in the treatment of this pulp were:

Camphor oil	0.03	lb. per ton of ore
Eucalyptus oil	0.46	" " " " "
Coal-tar	0.324	" " " " "

The foregoing figures represent the actual recovery obtained from the pulp passing through the primary flotation-cells. The final high-grade concentrate is the result of treatment of the primary-froth in cleaner cells, in which mechanical agitation also is employed. A mat-

Volume, Cubic Yards:

$$V = 47.4 C_0 + 20.92 [h_1 + h_2 + h_3 + \dots + h_{12}] + 13 [C_1 + C_2 + C_3 + \dots + C_{12}] + 0.909 [C_1 S_1 + C_2 S_2 + C_3 S_3 + \dots + C_{12} S_{12}] + .007272 [C_1 S_1^2 + C_2 S_2^2 + C_3 S_3^2 + \dots + C_{12} S_{12}^2]$$

Or, Vol. of excavation in Cu. Yds. equals -

47.4 times center cut + 20.92 times sum of cuts on 35 ft. radius + 13 times sum of cuts at 62.5 ft. radius + .909 times sum of products of each cut at 62.5 ft. by its corresponding slope stake elev. + .007272 times the sum of the products of each cut at 62.5 ft. by the square of its corresponding slope stake elev.

The calculation may be most simply made in tabular form, by adding two columns, for C_s and C_s^2 , to the ordinary field notes, adding up cols. and multiplying sums by factors given. Take cuts to nearest tenth of a foot.

If cuts at 35' radius are not taken, formula becomes:

$$V, \text{ Cu. Yd.} = 25.25 [6 C_0 + C_1 + C_2 + C_3 + \dots + C_{12}] + .909 [C_1 S_1 + C_2 S_2 + C_3 S_3 + \dots + C_{12} S_{12}] + .007272 [C_1 S_1^2 + C_2 S_2^2 + C_3 S_3^2 + \dots + C_{12} S_{12}^2]$$

The above to be used only for sections 30° apart, slope 1 1/2:1, and radii as above.

TANK GRADE 105' DIAMETER FOR 37 500-BBL. TANK

Find in field:

Cut at center = C_0
Cuts at circumference, 30° apart = C_1, C_2, \dots, C_{12} (ft.)
Cuts at 30 ft. radius, 30° apart = h_1, h_2, \dots, h_{12} (ft.)
Elevations of slope stakes, S_1, S_2, \dots, S_{12} (ft.) above grade

Side slope 1 1/2:1

Volume, Cubic Yards:

$$V = 34.9 C_0 + 14.81 [h_1 + h_2 + h_3 + \dots + h_{12}] + 9 [C_1 + C_2 + C_3 + \dots + C_{12}] + 0.7636 [C_1 S_1 + C_2 S_2 + C_3 S_3 + \dots + C_{12} S_{12}] + .007272 [C_1 S_1^2 + C_2 S_2^2 + C_3 S_3^2 + \dots + C_{12} S_{12}^2]$$

GENERAL FORMULA, SMALL TANK-GRADES

Radius of Grade = R ft.

Cuts at circumference 30° apart = C_1, C_2, \dots, C_{12} ft.

Center cut = C_0 ft.

Slope stake elevations = S_1, S_2, \dots, S_{12} ft. above grade

Volume, Cubic yards:

$$V = .006464 R^2 [6 C_0 + C_1 + C_2 + C_3 + \dots + C_{12}] + .014544 R [C_1 S_1 + C_2 S_2 + \dots + C_{12} S_{12}] + .007272 [C_1 S_1^2 + C_2 S_2^2 + \dots + C_{12} S_{12}^2]$$

The above apply only for sections 30° apart and other conditions as stated.

ter of further interest is the use of flotation as a method for discrimination between chalcopyrite and scheelite in a concentrate derived from the treatment of ore from the Soctarie mine, which is one of the same group occurring along a lime-contact with intrusive rocks of granitic type. The Soctarie ore averages about 0.3% tungstic acid, 0.35% copper, and 0.02 oz. gold per ton. From this over 30% of the gold is recovered, 6% of the copper, and 51.86% of the tungsten. Scheelite elsewhere has been

shown to be amenable to flotation with the common oils. It is interesting to note that it behaves differently with eucalyptus and camphor oil. Selective action is one of the most promising fields for the extension of flotation methods. Supplementary to cyanidation it is proposed to re-grind all oversize products in the mills of this company to minus 100-mesh in ball-mills, in order to render flotation more effective. By this means it is expected to improve the total extraction of valuable metals.

Report of the Canadian Nickel Commission

Nickel has often been referred to as a Canadian monopoly. While this is not strictly true, Canada does actually dominate the nickel market of the world. For many years the Dominion has sought to encourage the industry, and particularly to stimulate the refining of the metal at home. Recently a commission consisting of George T. Holloway, Willet G. Miller, and McGregor Young, with Thomas W. Gibson as secretary, was appointed to study the nickel problem. Their report has just been issued, making a volume of 600 pages, dealing with the nickel resources of the world, the mines, and the methods of reduction of the ores.

Two large plants for the refining of nickel are being erected in Canada. One is the property of the International Nickel Co. of Canada, Ltd., situated at Port Colborne. The company has obtained a site of 400 acres on which 2000 men are now at work. The initial output will be approximately 15,000,000 lb. of refined nickel per annum, provisions being made for doubling or quadrupling this capacity. The matte to be refined here will come from the smelters of the Canadian Copper Co. at Copper Cliff. For the treatment of this there will be required bituminous coal, coke, fuel-oil, nitre-cake, and other chemicals and materials, estimated at 100,000 tons annually. The plant is expected to be in operation by the autumn of the present year. The second refinery is that of the British America Nickel Corporation, Ltd., controlled and largely financed by the British Government, which has purchased the large Murray mine, the Whistle, and other deposits in the Sudbury region. This refinery will be erected at the Murray mine, about three miles from Sudbury. Electrolytic refining will be employed, using the Hybinette process. This is now in successful operation in Norway. The output of the Murray plant will be 10,000,000 lb. of nickel per annum. A custom smelter may also be erected as a stimulus to owners of nickel deposits of minor importance. The suggestion that the Government expropriate the deposits and plants of the Sudbury nickel area and operate them as a State monopoly has been discouraged. The commission points out that it would involve an outlay of more than \$100,000,000, a sum equal to the total paid-up capitalization of the chartered banks in Canada, and that no certainty exists of being able to make adequate profits on so large an investment. In the past the output

has had to be curtailed at times. If the price of nickel should fall, profits would naturally decrease. The nickel industry is to a considerable extent dependent for its success on the highly trained and specialized technical men who superintend it, and such men command salaries far beyond those paid in the government service to the most highly placed employees.

The ore-reserves of the Sudbury district are estimated at 70,000,000 tons of proved ore, and the total of proved, probable, and possible ore is put at 150,000,000 tons. The mines of New Caledonia are declared to be small compared with those of Canada. The largest yet worked has yielded 600,000 tons, and few of the New Caledonian deposits exceed 250,000 tons. The ores are richer than those of Sudbury, but are gradually showing a decrease in nickel-tenor. Neither do they contain copper and other valuable accessory metals. The cost of the refined nickel produced from the New Caledonian ores before the War was about 19c. per lb. At the present high prices for the metal it can be produced at a good profit, but below 25c. per lb. it might be difficult to keep these mines in operation. The deposits of Norway resemble those of Sudbury, but are leaner in both nickel and copper. They are also of smaller size, and are incapable of large expansion. Minor occurrences of nickel are known in Germany, Austria, France, China, Russia, Egypt, Italy, Tasmania, and the United States. Deposits similar to those of New Caledonia are found in Madagascar, but they have not been developed. Large bodies of nickeliferous iron-ore have been discovered on the island of Seboekoe near Borneo, and similar deposits have been worked for seven or eight years in Cuba.

The production of nickel as a by-product was investigated by the Commission. It is of considerable importance, and comes mainly from the electrolytic refining of blister copper, as copper ores almost invariably carry a small proportion of nickel. About 815 tons was obtained in 1915 through the refining of copper in the United States, and the tremendous increase in the production of copper will largely increase this quantity. In addition, scrap metal containing nickel is continually being re-treated and the nickel recovered. The importance of the precious-metal contents of the Sudbury ores has not in the past been fully recognized. These consist of gold, silver, platinum, palladium, iridium, and other rare ele-

ments. The proportions of these metals in the ores are minute and appear to vary in the several deposits. Roasted matte from one of the companies showed 0.1235 oz. platinum, 0.197 oz. palladium, 0.027 oz. gold, and 1.84 oz. silver; in another case the matte showed platinum 0.988 oz., palladium 0.984 oz., gold 0.256 oz., and silver 6.155 oz. per ton. Platinum is scarce and the price unusually high. Palladium is being substituted for it wherever possible. Both of these metals are now worth at least five times as much per ounce as gold.

The great use of nickel is in the manufacture of nickel-steel, the ordinary form of which contains about $3\frac{1}{2}\%$ of the metal. Compared with ordinary carbon-steel, nickel-steel has much greater strength and ductility, and is used in a wide range of industrial operations, in the manufacture of armor-plate, ordnance, projectiles, protective deck-plate, gun-shields, and other classes of naval and military equipment. Large bridges at New York, and over the Mississippi and Missouri rivers, dams, docks, the spillways on the Panama canal, and other large structures, illustrate the usefulness of nickel-steel. For locomotive forgings, marine engines and shaftings, wire cables, automobile parts, and the like there is a large and growing use. Many useful alloys of copper and nickel are produced, used for various purposes, such as bullet-casings, and plumbers' supplies. The use of nickel in the electro-plating of metallic objects is widely known. As finely divided metal, nickel is used as a carrier of hydrogen in the manufacture of fats from oils. This property of nickel causes it to be used by soap-makers. Pure nickel is used in coins, in the manufacture of watch and cigarette cases, and for cooking utensils. It is also drawn into wire for use in spark-plugs and electrical leading-in wires. Large buyers and consumers in Great Britain and the United States express the opinion that the uses of nickel will be extended, and that when normal peace conditions are restored, the demand will prove to be greater than before the War. A reduction of the price would undoubtedly increase the consumption and necessitate increased production.

The report also refers to a possible product from the Sudbury ores and slags, namely, nickel-copper-steel. A prejudice has existed against the presence of copper in steel, but recent tests have shown that the objections were not in all cases well-founded, if the copper percentage is not too high. The presence of a limited proportion of copper in steel is beneficial for some purposes, and it is also capable of advantageously replacing a proportion of the nickel in nickel-steel up to at least one-third of the combined quantity of nickel and copper. Experiments made for the Commission by Prof. George A. Guess, of Toronto University, fully confirmed these conclusions. Copper unquestionably gives steel greater resistance to corrosion, as demonstrated by elaborate tests conducted at the School of Mining of Queens University, Kingston, Ontario.

THE WOLFRAMITE OUTPUT of Siam increased from 602,267 lb. in 1915 to 950,400 lb. in 1916, the entire

amount having been mined in the district of Nakawn Sritamarat, in the Siamese Malay States. The producing area has increased, and with the present high prices a still larger output may be anticipated. In the district of Trang, tungstate of calcium, scheelite, has been found, and is being worked on a small scale.

New Process for High-Grade Silver Ore and Concentrate

A plant has been erected recently by the Cobalt Reduction Co. for the treatment, by a new process, of high-grade ore and concentrate. The method was worked out by M. F. Fairlie, who demonstrated that after a preliminary treatment with bleaching powder ($\text{Ca}(\text{ClO})_2 + \text{CaCl}_2$), this combination of minerals can be successfully cyanided. The low-grade ore is concentrated in the usual way on tables, the slime going direct to a cyanide annex. The table-concentrate is re-concentrated on tables and brought up to 2000 oz. silver, while the tailing is sent to the cyanide-plant with the slime. The rich concentrate, together with the high-grade ore, is then ground wet for 24 hours in a tube-mill equipped with iron linings and balls. Toward the end of the operation, 2% of bleaching powder is added. The bleaching powder oxidizes the refractory silver minerals making them amenable to cyanide treatment. The tube-mill charge goes to a Dorr classifier, where the metallics from the ore are removed together with the sand. The pulp is de-watered by an Oliver filter, and the treatment by strong cyanide-solution follows. The residue after filtration is sold on the basis of its cobalt and silver content. The silver-bearing solution is precipitated by sodium sulphide. The resulting precipitate is de-sulphurized in a small tube-mill by metallic aluminum and caustic soda. The silver is melted to fine bullion in a hearth-furnace. The oversize raked out by the classifier is given a low roast to eliminate part of the arsenic and is then melted to bullion. The small residue of speiss and slag is returned to the tube-mill with the next charge. By this simple process the corporation which was formerly one of the largest shippers of ore and concentrate in the district is enabled to market practically its entire output in the form of fine silver bar.—R. B. Watson in *Canadian Mining Journal*.

MAGNESITE is used largely as a refractory lining for the tilting furnaces in open-hearth steel manufacture; also for sorel cement in wall-panels and flooring, and as a filler in paper. The raw magnesite is calcined at a temperature between 400 and 650° C. For use as a refractory material the prevailing specifications of buyers call for a minimum of 85% MgO , less than 6% SiO_2 , less than 4% CaO , and less than 5% loss on ignition. No limit is placed upon the Fe_2O_3 content, although actually the calcined magnesite sold for this use carries about 7%. For use in sorel cement and as a paper-filler the silica content may run as high as 12%, no limit is fixed for CaO , while Fe_2O_3 must fall below 1%.

Ventilation in the Rincon Mine

By BLAMEY STEVENS

Considering the extent to which the science of ventilation has been carried in coal mines, the lack of knowledge of most metal-mining engineers on the subject is notable.

Where natural ventilation is insufficient, we often see great sheet-iron pipes going down one or more of the several shafts of a mine or system of mines. This generally unnecessary, expensive, and cumbersome equipment is often fitted with a blower whose design is out of all proportion to the necessities of volume and pressure. In saying this, I do not forget that some of the better conducted metal mines have systems of ventilation rivaling that of any coal mine. The practice, as it applies to metal mines, has to be suited to the altered conditions, however, and the general principles should be better described in mining literature.

In metal mines, natural ventilation is for the most part relied upon, and in addition, air is carried to, or taken from the working-faces, where necessary, by means of pipes. In coal mines no pipes are used, but, as natural ventilation is entirely insufficient to keep dangerous gases from accumulating, a strong draught is forced through all the passageways of the mine. Development is carried forward by simultaneously driving parallel drifts in the vein or bed, and connecting them at intervals of a few feet. The current of air is trained by doors, etc., to pass up one of these drifts to the face and come back the other, thus scouring out all gas within a few feet of the working-faces.

This arrangement generally fails to interest the metal-mining engineer, for two reasons: he thinks the cost of a large ventilator and power to run it must be excessive, and he objects to the cost of running two drifts together.

In regard to his first reason: The average metal mine does not need a large draught; 20,000 cubic feet of air per minute is generally sufficient, and this can usually be got through the main drifts, with a loss of pressure equal to a half-inch of water-head. Work this out and it gives about $1\frac{1}{2}$ horse-power, or, allowing for an efficiency of 50%, say 3 horse-power.

Such a ventilator would be about six feet in diameter, and its cost, in sheet-iron, a mere detail. It may be installed over a disused shaft or down the mine at the lowest level that has ceased to be much used. The latter position is generally preferable, as otherwise the old workings may short-circuit the current. All short-cuts that the air might take must be well boarded up and the cracks caulked. Men used to natural ventilation never give enough attention to the proper caulking. If doors have to be made, they should fit tight.

There are two or three forms of ventilator, but I think that known as the disc type is best suited to metal mines.

The volume of air is calculated from its velocity in a drift, this velocity being measured with an anemometer, which can be bought from the instrument makers. The difference of pressure created by a fan is measured by a manometer, which can be made in the assay-office. It is simply a piece of glass tube bent into U form and charged with colored water. One end communicates with the higher and the other with the lower pressure. The difference in level is the pressure as water-head, and may be measured with any rule. The fan should be suitable to the pressure and volume conditions. All the makers supply tables of the performances of their several sizes and types of fans.

It must be remembered, however, that no fan can reduce the resistance of the air-passages. For good results these should be as open as possible. Points in the main circulation that one can just crawl through are ridiculous. If only the manways of raises are available, the air should pass through three or four raises in parallel, so as to make the equivalent area of a drift.

It is hard to estimate what the resistance of any particular circuit of a mine may be. It is immediately obvious, however, when any kind of mechanical ventilation is installed, because the pressure is proportional to the square of the cubic capacity of air delivered.

The square of this delivery, divided by the pressure, therefore becomes the frictional constant, depending only on the length and shape of the passages traversed. With this constant determined by any one ventilator, the proper pressure for any desired capacity may be immediately calculated, and thus the most suitable ventilator or speed be designated.

In choosing a ventilator, it is best to get one larger than necessary rather than the reverse, for speed can always be reduced below what the maker specifies, though it should not be increased.

In a metal mine where two levels are being used at the same time, the draught may follow the vein to the limit of the mine, on, say, the bottom level, and then return on the one next to the bottom. When it reaches the raise nearest the shaft it may ascend to the old workings and thence out of the mine.

Plenty of cool dry air prevents timber from rotting, cools hot stopes, sweeps out unhealthy, bad air, and increases general efficiency, to say nothing of 'welfare.'

The best way for the air to travel is down the main shaft, so that this, with its expensive timbering, pipes, electric lines, cages, skips, cables, and other equipment, may be kept as dry and cool as possible. The pump-stations get the next benefit of the air and then it goes to the development-faces.

If the draught refuses at first to be turned back down the shaft, water may be sprinkled down from a hose, but if the shaft is normally dry, one should look out for the loose stuff behind the lagging.

If necessary for the more efficient working of the fan, the resistance may be reduced by making two short circuits instead of a single long one. The violence of the draught is then decreased, but not the average freshness of the air. In order to split up air-currents properly, it may be necessary to insert an artificial resistance in one of the circuits.

The average shift-boss has a fixed idea that the velocity and the inertia of the current are what makes it travel. Disabuse his mind of this illusion. It is the fall of pressure that counts.

As for the double drift for the blind development, there are several ways of getting around it. If the drift

Three large fans, placed advantageously, now ventilate this mine, with draughts fit to blow one's hat off, so that after four years timbers show little or no sign of rotting. Contract-prices were cut 30% on the average, and 50% in some places. Other improvements, however, also contributed to this effect.

The method of development now followed is to drive in the foot-wall country a straight drift of 0.5% gradient and having the mean course of the vein. Practically no timber is used. Winzes, also in the foot-wall, are sunk every hundred metres, this being found sufficient, seeing that the gaseous water is tapped only in the vein. When connection is made with a winze, and the draught established, the vein is tapped with a short cross-cut and allowed to drain, the main drift proceeding meanwhile. After the vein has drained itself down to a normal flow, it is found that from 25 to 30 metres can be driven on the

LOWER LEVEL OF RINCON MINE.

is in ore, one can often break a heading for the stope a few feet behind the face of the drift and use this embryo stope for the return air-current. To ventilate a raise from this, connect the man-way to this stope and the ore-way to the main drift. If inconvenient to keep the ore drawn off, tap it a few feet higher, on the opposite side of the man-way. If progress must be forced, put down winzes from the level above, when there should be no trouble about ventilation. If nothing else can be done, one may string electric wire from the pump-station to run a small portable electric-driven fan at the end of a few feet of pipe running from the last raise. This is more efficient and economical than placing pipe the whole length of the drift.

For the last few years I have had to deal with what, as far as I can learn, is the most 'gassy' metal mine in the world, the Rincon in the State of Mexico, a mine of medium size, producing, under favorable political conditions, about 18,000 kilo. of silver per annum.

A large spring of tepid carbonated water has its source in the mine, and had retarded its development for twenty years. There were literally miles of pipe, but the air that they carried in or out was nothing compared with the carbonic acid gas that bubbled up everywhere on the lowest level. Because of the weight of this gas, natural draught would not raise it, except when the heat was excessive, and then but poorly. When conditions became unbearable to the men at the pump-station, which happened several times each day, they would turn live-steam up the shaft. From its mouth there generally issued a cloud of steam, which could be seen for miles. The timbers in the shaft were renewed yearly, and the rest of the mine-timber was changed almost as frequently.

vein without any difficulty in ventilation. This is somewhat remarkable; it is owing to the fact that the carbon di-oxide gas runs out along the bottom of the drift without seriously contaminating the air at the level of a man's head. This flow, however, will take place only for about the limited distance mentioned, after which, under normal working conditions, the level of contaminated air becomes sufficiently high to interfere with breathing.

Needless to say, when once diffused into the air, the carbon di-oxide never again separates and the whole volume must be swept from the mine as quickly as possible.

The vein is tapped, as often as necessary, from the main or working drift in the foot-wall. The subsidiary or vein-drifts are driven through and timbered on a more or less temporary basis, and only when ore is needed. These drifts are run only where there is workable ore. Enough of the air-current goes through the subsidiary drift without the use of doors. Raises are then put up in the workable ore without difficulty, and being connected above, and the resultant draught properly controlled, stoping operations can begin. After a part of the vein is worked out, the timbering is not renewed, but preparations are made for the protection of the stopes to be brought up from below.

While this method is primarily made necessary by the carbon di-oxide, it is probable that, even without the gas, it would not be more costly. No exact estimate of this comparison can be made from former figures of cost because of the difficult conditions then existing for driving on the vein. As an indication of these difficulties, the average gradient was 3%, owing to the fact that shift-bosses would not go to the faces to inspect the work. Only men bred in the district would work there. These

men worked after the manner of pearl-divers, laboring a few minutes and then going to put their faces in the mouth of the air-pipe for about an equal length of time. The crookedness of the vein on such a steep grade gave endless trouble in transportation and the steep gradient limited the water-storage capacity of the lowest level, so that, after three or four hours without pumping, the water would rise to the motors.

Although it has not been tried, we are satisfied that two 100-ft. levels might be taken together, the main foot-wall drift being driven only on the lower level, and the intermediate on the vein.

After the vein is drained and the auxiliary drifts put through, no carbon di-oxide appears above, because the ventilated drift keeps the gas from rising further in the vein. Nitrogen gas is found, however, in the raises and in blind drifts, this being due to the abstraction of the oxygen of the air by the decomposition of the sulphides. This well-known condition occurs in many localities and need not be dwelt upon here. As the gas is formed only above the bottom level, it presents no difficulty in a well-developed mine.

The difference of effect of the two gases is interesting. We find that a man easily lives in a nitrogen-charged atmosphere containing so little oxygen that a candle will not burn in it. Breathing is then only made more rapid as a result of physical exertion. The effect is apparently the same as that from a high altitude, the heart-action being rapid, so that probably the same amount of oxygen is distributed by the circulation through the body.

With carbon di-oxide, the reverse is the case. Quick deep breathing begins at once, and a candle will burn where a man falls unconscious. The greater relative effect on a man is probably due to the extreme solubility of carbon di-oxide. By solution it displaces oxygen in the blood. In the burning of a candle no solution takes place, so that the carbon di-oxide then acts only as an inert gas, much in the same way as nitrogen.

Carbide light is best for both gases, but the usual jet necessary for bright combustion, must be done away with as it blows itself out. A manner of temporarily remedying this is to make a little soft clay cap in front of the burner so as to direct a slow stream of the gas at a right angle to the usual direction of the jet.

THE USE OF the wet, sloppy mixture in making concrete, that has characterized recent American practice, is being changed in favor of the drier mix advocated by engineers 15 or 20 years ago. The dry mix is more homogeneous and durable. It is well-known that, with a moderate amount of water, the apparent moisture in the mix, and its consequent mobility, increase by somewhat prolonged mixing. Cement so prepared is superior to that poured very wet, and should be adopted always for the foundations of large engines and other machines. The use of the wet mix has been the out-growth of competition among contractors; shortening the time of mixing the concrete saves cost.

Laterite and Bauxite

Laterite is a term frequently mis-applied. Its technical use is to indicate a peculiar type of residual deposit resulting from the sub-aerial decay of igneous rocks under climatic conditions of high annual mean temperature and abundant moisture, involving areas that had been subjected to base-level erosion or at least to peneplanation, in districts favorable for the growth of excessive vegetation. The conditions favoring the accumulation of laterite, therefore, are those of the tropical jungle. The action of vegetable acids and abundant carbon di-oxide in the seepage-waters results in intensive kaolinization, with the removal of the excess of silica. In consequence a deposit of laterite is composed chiefly of clay and various hydrous aluminum silicates, together with large quantities of ferric oxide. The color is accordingly a deep iron-red. Laterite is essentially the home of bauxite, the hydrated oxide of aluminum, which is the necessary product of extreme de-silicidation, taking place in rocks subjected to the action described. The laterite deposits in the United States are remnants of those formed during the Mesozoic era, when tropical conditions prevailed over large parts of North America. The most extensive areas of these Mesozoic laterites are found in Arkansas, Alabama, and Georgia, and they are accompanied by valuable deposits of bauxite. Great lateritic zones are reported from the Guianas, from southern Venezuela, and from the interior basin of South America, said to hold important resources of this highly desired ore of aluminum.

MANGANESE ORE is at present sold in the Eastern markets in accordance with the following schedule: the long ton of 2240 lb. is the basis of calculation; in ores containing from 40 to 43% metallic manganese, payment is made at the rate of 71c. per unit of the metal; from 43 to 46%, 75c. per unit; from 46 to 49%, 78c. per unit; above 49%, 80c. per unit. The above prices are based on ores containing not to exceed 8% silica nor 0.2% phosphorus. Deductions from these prices are made as follows: for silica in excess of 8%, a deduction at the rate of 15c. per ton for each unit; for each 0.02% phosphorus in excess of 0.2% a deduction of 2c. per unit of manganese per ton, with fractions in the same proportion. Ore containing less than 40% manganese or more than 12% silica, or over 0.225% phosphorus are subject to refusal. Settlements are made on the basis of dry weight of ore determined on analyses of samples dried at 212°F. As all metal quotations are subject to change without notice confirmation of prices by wire should be obtained in advance of shipment. The figures given are f.o.b. Pittsburg, Chicago, and Atlantic terminals.

DE-VITRIFICATION of fused silica, known as 'quartz glass,' is due to a tendency to crystallize when the temperature is below that of the fusion point of cristobalite (1625° C.). When it passes the inversion-point at 200 to 275° it tends to break up as a chalky de-vitrified mass.

Aluminum-Dust Precipitation Tests

From Notes by P. H. CRAWFORD

The following article is from data obtained in tests made at the Divisadero mill in the Republic of Salvador.

In making the tests everything was done to imitate working practice as nearly as possible. Enough ore was ground in the assay-office for the entire series of tests, thus affording the same metal-content throughout, the pulp having been well sampled at the start. The ore was battery-feed saved from several days' samples and ground to pass 150-mesh, except for 2.57%. Two small pachuca vats were used. With a few inches to spare they held 44,000 cc. of solution and 11,000 gm. ore-feed. This gave a ratio of 4:1. Except for the third test, which had only 50 hours' treatment, they received 60 hours' air-agitation. Using the two tanks mentioned, we were able to treat 22 kgm. of ore per charge. For filtering the pulp a small Johnson press was secured. It held a little more than a single pachuca charge, but by pumping only one charge at a time, room was available between the cakes formed in each space to give a water-wash, that being necessary to compensate for the loss in moisture and solution used in making titrations and assays, and also to bring the filtering practice nearer to that on a working-scale. For the precipitation of gold and silver from the solution and for preventing the re-solution that takes place when filtered in contact with air, a small press was used, to which was connected a small pump, and, after the necessary time of contact, the solutions were passed through. These presses were attached to the pumps. The pump from the slime-press was connected by a small hose to the bottom of the pachuca vats, so that the pulp could be drawn direct, and, when the vat was empty, could be given a water-wash and that solution pumped through the cake and used in the next test for making up to the proper strength.

To precipitate the lime from the solution after treatment, and before precipitation of the precious metals, soda-ash was added to the pulp-charge about two hours before filter-pressing it, the solution coming out ready for precipitation, and the lime going with the tailing. Soda ash is added as a preparation for aluminum-dust precipitation in order to remove calcium from the solutions. In so doing it generates the caustic soda required for the purpose, according to the reaction: $\text{Ca(OH)}_2 + \text{Na}_2\text{CO}_3 = 2\text{NaOH} + \text{CaCO}_3$. If calcium is not removed it gives rise to a very troublesome precipitate of calcium aluminate, which lowers the grade of the silver precipitate and renders it difficult to melt. The solution from the press was so clear that it was not necessary to filter before titrating. This was true, even when testing for free KCN, where the end-point cannot be determined unless the solution is perfectly clear. The amount of soda-

ash used is given, and also the results obtained on each test. It will be found that more sodium carbonate was used in the last test than in the others, due to the fact that more caustic soda was required for precipitation of the gold and silver. Therefore an excess of lime was added in starting the treatment, making it necessary to add more soda-ash to precipitate it. This gave the needed caustic. On a working-scale the solutions would have enough, and even less would be used. It is not necessary to have excess lime, unless required for settling pulp.

The solution coming from the pulp-press was run direct to an iron drum used for mixing the aluminum-dust. In practice it would be the contact-tank, but in that case it would be necessary to have two of them. Indeed, we should have used two, but this would have made more work for the shop, as the necessary connections would have taken time. The reason for using two tanks is that no air should come in contact with the precipitate after being formed. Having two tanks, the solution entering the top of the first, with the necessary aluminum-dust, is at once given violent agitation; the solution passes downward on its way to the outlet placed near the bottom, from which point it rises through a pipe to the level of the solution in the first tank, which it had just entered, and then passes downward to the next, where it enters the side near the bottom and is retained as long as necessary for precipitation, meanwhile being violently agitated to keep the precipitate well divided and to expose fresh aluminum-surface as the precipitate is washed from the metal-particles by the agitation. In using one tank it proved necessary to keep the solution agitated as much as possible by stirring with a wooden paddle. The amount of air taken into solution in this way and passed, after precipitation has taken place, to the vital part of the process, namely, the pressing, is open to question, but for small test-work the results as a whole are not bad. It must be stated, however, that an excess of precipitant was found necessary to bring the solution-tailing as low as we did. The clear solution from the presses would point to an exceptionally rich precipitate in practice. The ratio of solution to ore was 4:1, in order to be able to use a sufficient quantity for check titrations, assays, etc., in case of necessity, and also for the reason that, though in practice the ratio of pulp to solution in agitation is 2:1, in the mill the ore comes in contact with 7 to 10 times that amount of solution. In this test the amount of soda-ash used was twice what it would be in actual practice. In making small tests it seems impossible to secure total precipitation with the amount of aluminum-dust sufficient in large-scale operations. The proper amount must be ascertained in the works.

A lower strength of solution was used than is at pres-

ent employed in the mill while precipitating with zinc. If this should be found strong enough in actual practice with aluminum there is a further saving to be made in cyanide, and from the results on the four tests I see no reason why the lower strength could not be used. If a stronger one be employed the extraction should be even better. It must also be borne in mind that the ore used in these tests was finer than that treated in the large pachucas in the mill, that is, there was less plus 150-mesh material, though perhaps the quantity of minus 150-mesh was on the whole not so finely comminuted. The extraction in actual practice should, if anything, be a little better than that shown by the small tests, due to the fact that an excess of aluminum-dust is used for precipitation, and if there were a tendency for aluminum solutions to become foul it should show up here. As a matter of fact almost the same extraction was obtained in the last test as that in the first when the solution was new. I doubt that this could be done with zinc-dust, even using the exact amount necessary for precipitation, or using the same ratio as maintained in the mill, in spite of it being extremely low. The average extraction in the four tests, including the 50-hour agitation, was as follows: silver 92.59%, gold 98.48%, total 94.14%. This is the percentage dissolved up to the time the solutions are treated with soda-ash. If there is any great loss in the filters, or if no further extraction takes place there to overcome the loss, the foregoing figures would not hold on a working-scale, although that would not be due to any fault of the solutions.

The details for successful precipitation are hard to settle in these small tests. There are many things to be overcome on a laboratory test that are taken care of in practice by arrangement of the proper tanks, whereby no air may enter the solutions after precipitation begins. The rate of flow, length of contact, and amount of aluminum-dust fed are mechanical details that have been overcome and are now doing good work in several plants. To make a test that would overcome all these difficulties, it would be necessary to have miniature tanks, pumps, presses, dust-feeder, etc., with the necessary pipe-connections and valves, so that every stage of the process could be regulated as in large-scale work. If the least air is allowed to enter the press, or reaches the precipitate, there will be some precious metal re-dissolved and the tailing will run high. In making the small tests, everything possible was done to overcome this, the resultant tailing-solutions being generally low. Two of them were exceptionally low for this kind of work, but for some reason the gold would not come down like the silver. I am told that this is also true with the zinc-precipitate in present practice.

To arrive at the necessary amount of aluminum-dust that would be required to precipitate the gold and silver per ton of ore, a series of precipitation tests were run. On using up all the solution from the last test, that being the fourth time it was used, the residues were sent to the assay office. When the returns came it was seen that something had gone wrong with all but the first three.

On looking over the pump and press used for that test, a small hole was found in the rubber tubing employed as pump-suction. Beyond doubt that was the reason for the high tailing in all but the first three tests, though the amount of aluminum-dust used in most of them is lower than the previously estimated 0.43 lb. per ton.

The details of the tests are shown in the accompanying table:

Test No. 1. In starting the tests a new solution was made up, taking 88,000 cc. water, to which was added 172.48 grammes NaCN and 242 gm. lime. The solution was then mixed with 22,000 gm. battery-feed ground in the assay office, so that all of it passed 150-mesh except 2.67%. In this test, as well as in the other three, the ratio of solution to ore was 4:1. The soda-ash necessary in practice would have been 2 lb. per ton of ore treated. Agitation was accomplished in two small pachuca vats, using air, the time of contact being 60 hours. To test No. 1 was added aluminum-dust at the rate of 0.70 lb. per ton of ore. This was added little by little to the bottle in which the contact was being made, so that perhaps the third part was added during the last 5 minutes, the total contact-time being 15 minutes. The bottle was agitated by hand to wet the dust and then placed on the rolls.

Test No. 2. In this test the solution from No. 1, after precipitation, including the water-wash, was used. To bring this up to the necessary strength 58.64 gm. NaCN and 156 gm. lime were added. The water-wash was used to make up for that lost in moisture, in titrations, and for assay. The same amounts of ore and solution were employed. The treatment was also identical. The soda-ash in practice would have been equivalent to 1.5 lb. per ton of ore. Test No. 2 had the same amount of aluminum-dust added, but was violently agitated by shaking the bottle, this being kept up during the whole time, the dust having been introduced as a whole at the start, and the cork not being removed until it was time to pump through the press.

Test No. 3. For this test the precipitated solution from the previous test, with the wash-water, was taken. To bring this solution up to the necessary strength 45.74 gm. NaCN and 187 gm. lime were added. Just enough wash-water was forced through the pulp to make up for that lost in moisture, titration, and assays. The same ratio of solution to ore was used as in previous tests.

The soda-ash necessary to precipitate the lime after treatment, which is before aluminum precipitation, was at the rate of 0.9 lb. per ton of solution, and in practice would have been 1.8 lb. per ton of ore. The extra lime was added to bring up the strength in caustic. Test No. 3 was made in a smaller bottle and 0.35 lb. of aluminum-dust added. It was corked and placed on the rolls for one hour; then pumped through the press.

Test No. 4. The precipitated solution from the previous test was used, plus the wash-water that was passed through the cake in the presses to make up for the amount lost in moisture, titration, and assaying. To bring the solution up to strength 48.62 gm. NaCN and

242 gm. lime were added. The extra lime was used for the purpose of bringing the solutions at the end of the treatment nearer to the strength that would be used in actual practice. This necessarily demanded more soda-ash on this test, but in actual practice it would not, as the caustic that it is endeavored to get in this way would be in the working solutions. The soda-ash would be equivalent in practice to 2.50 lb. per ton of ore, but this would be less, as the necessary caustic would be present. In addition to the above, other tests were made which were faulty. The higher results were probably due to accidental admission of air. A résumé of results from the additional tests is given in the table below:

0.10 lb. lead acetate was added. It is suspected that the cork in this case may have been removed by an assistant. These tailing-assays are high, including those with an excess of aluminum-dust. Some precipitation-tests were made in pails, in which the aluminum-dust was added and stirred with a wooden stick for 35 minutes, but the resulting tailing was so high that they were valueless.

The conclusion to which the tests lead is that an important saving in cyanide is effected by using aluminum-dust for precipitation instead of zinc-dust. In summary, the advantage gained is approximately 1.6 lb. cyanide saved by regeneration in precipitation; 0.35 lb. saved in the washing in the presses; and an economy of 0.15 lb.

Number of test	Aluminum-dust used, lb.	Time of contact	Method of agitation	Tailing assay silver oz.	Tailing assay gold, oz.	NaOH
4	0.30	20 min.	Shake-rolls	0.53	0.021	0.0897
5	0.55	20 "	" "	1.66	0.011	0.0487
6	0.30	X 20 "	" "	0.49	0.020	0.0487
7	0.35	X 30 "	Shaking	1.05	0.032	0.0487
8	0.35	X 15 "	"	0.72	0.030	0.0487
9	0.65	X 60 "	Rolls	0.475	0.018	0.0487
10	0.35	X 30 "	Shaking	0.64	0.021	0.1300
11	0.35	X 15 "	"	0.45	0.019	0.1300
12 (lead acetate, 0.1 lb.)	0.35	? 15 "	"	1.84	0.030	0.0487

Those having X before the time-item had the cork in place during agitation, in order to keep the air out as much as possible. The only air admitted was that in the bottle, in the space allowed for agitation. In the last test

by reason of the lower permissible strength of solution for equivalent results. The total saving effected is, therefore, about 2.1 lb. in the case of the ore on which the experiment was made.

EXTRACTION OF PRECIOUS METALS BY ALUMINUM-DUST PRECIPITATION

Concentrates

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

CRITICAL TEMPERATURE is the point above which any substance will remain in a gaseous state without reference to pressure.

LITHARGE used by assayers always contains a small amount of silver and sometimes a little gold. The presence of these metals can be determined and proper allowance made by the assayer therefor.

MICA employed as an insulator in electrical work must be free from iron minerals and other foreign substances, or its value for this purpose will be impaired in proportion to the amount of foreign mineral present.

EXPANSION of alloys on cooling is sometimes important. A mixture of one part bismuth, two parts antimony, and nine parts lead will expand upon cooling, which makes it useful for certain purposes. Most metals and alloys shrink upon cooling.

THE PROPERTIES of ferrous oxide, FeO , according to Robert B. Sosman, are still practically unknown. Most of the methods by which it is prepared yield only a mixture of metallic iron, or of an iron carbide, with an oxide having a composition falling between FeO and Fe_2O_3 .

INSTEAD of inquartation a Central City, Colorado, assayer introduces into the assay-charge, after it has been put into the crucible, a measured quantity of standard silver-nitrate solution, then adding the salt-cover. The silver-nitrate solution is drawn into the charges from a burette.

HYDRAULIC-JACKS are among the handiest tools to have about a mine. Their usefulness cannot be overestimated. No mine should be without one or more of them. They are useful on the surface, but more so under ground. The common track-jack, though less powerful, is a most useful device, and there should be one of every level of a well appointed mine.

A BLAST-FURNACE was built several years ago at Butte, Montana, which was 72 inches wide at the tuyeres. It is said to have worked well with coarse ore, but was unsatisfactory with the usual run-of-mine ore, which contains a great deal of fine material. This renders successful smelting in so wide a furnace impracticable. The usual working height of the ore column in a blast-furnace over 36 in. wide at the tuyeres is about 14 feet.

RADIUM-BARIUM SULPHATES carrying considerable silica may be readily converted into carbonates by fusing with a mixture of sodium carbonate and hydrate, as determined by recent experiments in the laboratory of the

Bureau of Mines at Golden, Colorado. The amount of sodium carbonate required ranges from 10 to 15%. The reaction occurs at a low temperature. The product is easily washed free from sodium silicate.

CONCRETE in contact with sea-water undergoes serious changes in chemical composition. Concrete piers of a bridge across the Shrewsbury river, New Jersey, recently failed, and inspection showed stratification into alternate layers of a putty-like substance, sand, and gravel. Samples from the altered cement showed nearly equal parts of magnesium, calcium, and the oxides of iron and aluminum. The magnesium of the sea-water replaces the calcium in the cement.

PLACER MINERS give sluice-boxes a grade which in their judgment will accomplish satisfactory results, varying from 8 to 14 in. to the 12-ft. box. In some instances the grade is set lower than is deemed advisable owing to the low fall of the gulch or valley where mining is in progress. The boxes may be given a grade greater than the creek, in fact, this is generally necessary to keep the drainage clear. From 30 to 40 cu. ft. of water per minute is considered a 'sluice-head' for a 12-in. box.

DISCHARGE of water that will issue from the bottom of a tank or reservoir through a pipe of given dimensions depends upon the vertical length of the pipe, and the friction. A reservoir would be more quickly emptied if discharging through a 10-in. pipe, the lower end of which was 200 ft. below the bottom of the reservoir, than it would if the same pipe ended but 100 ft. lower than the bottom of the reservoir. Friction is a factor to be considered, particularly in long pipes.

OZOKERITE combines the chemical inactivity of paraffine with the physical properties of beeswax, that is, it possesses a peculiar plasticity that admits of its being kneaded. Its value is enhanced by the fact that its melting-point is higher than either paraffine or beeswax. Ozokerite, and its waxy derivative ceresin, are used in the manufacture of candles, as insulation for cables, and in shoe, stove, and floor-polishes. It is a hydro-carbon found in veins, and apparently formed as a result of distillation from highly altered carbonaceous shales and lignitic rocks.

PROSPECTORS who agree to go prospecting on a grub-stake cannot quit their backers at will. It is better to have a date distinctively stated limiting the term of partnership. Necessarily it involves honesty and fair dealing on the part of the prospector, who is supposed to search vigorously, using all the knowledge that his experience has brought him, for the common good. The prospector may find a rich deposit, and cover it up or fail to make the fact known until the term of his grub-stake agreement shall have expired, but an honest man will not attempt such meanness. In grub-staking the essential matter is a 'square deal' all around.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

LEADVILLE, COLORADO

IMPORTANT DISCOVERIES IN UNDEVELOPED TERRITORY.—PROPOSED TUNNEL PROJECT FOR PROSPECT MOUNTAIN.

What appears to be the making of one of the largest and richest mines in the Leadville district has recently been discovered near the Lackawanna, a territory that is rapidly coming to the front as an important gold producer. A large fissure-vein on the Ozark property adjoining the Mt. Champion has been opened within the last two months and an ore-shoot over 200 ft. long, 100 ft. high, and 2½ ft. wide has been encountered. The ore assays from 5 to 7 oz. gold per ton. The vein traverses the entire property of 98 acres and it is believed that the ore-shoot also will persist with the vein.

Shipping from the Ozark was started February 1, the first carload bringing a net return from the smelter of over \$3000. Since then, six other cars have been shipped, one of which, containing 35 tons, netted \$4100.

The Ozark is owned by John W. McMahon, B. H. Martin, John Cortellini, and Dorsey Almond. The property is under a five-year lease to the Mt. Champion Mining Co. and is being developed through advanced laterals from the workings on the third level of the Champion mine.

Other big veins are known to traverse the Ozark, and it is planned to undertake the development of a number of them during the coming summer. It is believed that this work will uncover several new ore-shoots of high value and place the property in the front ranks of the rich producers of the district.

The ore is white quartz containing free gold and occurs in big fissure veins in the granite.

For several years the Mt. Champion property has been producing a steady output of high-grade gold-bearing ore, some of which ran as high as \$1000 per ton. The veins from which this ore was extracted are the same as those that extend into the Ozark, indicating that continued development in the new ore-shoot will discover ore as rich as that found in the Champion.

The strike at the Ozark is undoubtedly one of the most important discoveries that have been made in the Leadville district during the last six months; a period during which some of the biggest and richest strikes in its history have been made. Interest and activity will surely turn to the Lackawanna territory early in the summer, as soon as surface work becomes practicable; and beyond doubt, the development then undertaken will uncover other rich shoots in the area surrounding the Mt. Champion and Ozark. The Lackawanna section offers numerous attractive mining opportunities, and the recent discovery will have a great bearing on their future development.

To keep pace with the rapidly increasing ore production from the district, the smelting and milling-plants are making the necessary extensions required for handling the tonnage. During the past year several important additions and improvements have been made at the Arkansas Valley plant of the American Smelting & Refining Co., and it is officially stated that others will be completed as soon as the equipment can be secured.

Simon Guggenheim, president of the A. S. & R. Co., accompanied by Edgar L. Newhouse, Carl Eilers, Henderson Green, and F. H. Brownell, president of the Federal Smelting & Mining Co., of Idaho, visited Leadville recently on a tour of

inspection and stated that extensive plans for increasing the capacity of the Leadville plant and carrying on the welfare work for the employees are now being perfected by the company.

"I am especially pleased to be able to announce that a fund of \$500,000 has been set aside for the welfare work in all of our plants, and while much has been done in the Leadville plant, we expect to add to this materially," Mr. Guggenheim said. "There will be shower-baths, club-rooms with pool and billiard-tables, and other accessories for improving the condition of the men. When necessary we will not only look after the welfare of our employees while they are at the plant, but will take an interest in those vital questions of home life and living conditions. Trained nurses will be provided when necessary, and other steps taken in looking after the families of our employees. We believe in dividing our profits with our men. Irrespective of this, wages have been increased in all our plants and every effort has been made to look after the best interests of our employees. It is the purpose of the company to increase the facilities for taking care of the increased production of ore which is being stimulated by the growing demand for metals. It is our aim to co-operate with the miners whenever additional extensions to our plants are required, for we fully recognize that their interests and our interests are identical. Of course, in times like the present, it is difficult to procure the necessary equipment for immediate delivery, but we are making special efforts in that direction. I find that the mines here are showing increased activity and that the town is more than holding its own. Leadville may well pride itself on being one of the premier metal-producers of the West, and our faith in its future is indicated by the fact that we are actively engaged in making whatever additions and improvements the conditions at our plant call for."

George Cramer & Co., leasing the Star No. 5, Ladder, Catalpa, Waterloo No. 1 and 2, and the Yankee Doodle, on Carbonate hill, are erecting a new jig-mill near their properties for the purpose of concentrating low-grade lead-iron ores, immense bodies of which have been found in those mines. The plant will be the first of its kind in the district, and has been demonstrated to be successful in handling this particular kind of ore. It is stated that the mill will begin with a 50-ton capacity but will be so built that new units can be added without difficulty. The plant will probably be ready for operation within two months.

The Western Zinc Oxide Co. has been considering a plan for increasing the capacity of their plant, and it is now reported that the work of enlarging will be undertaken this summer. As the plant now stands, it is capable of treating 60 tons of zinc carbonate daily. When the work of extension is taken up it is planned to install a roasting-plant so that sulphide ores also may be treated.

A large company, strongly financed, is being organized by A. A. Garrett, of Leadville, for the purpose of driving an adit into Prospect mountain from the Arkansas Valley side. The enterprise is regarded as one of the most promising in the district. The proposed adit will be several hundred feet below the workings in the Anderson tunnel, at Birdseye, or the Silver Spoon tunnel in the Big Evans gulch.

Ore has been encountered in the Silver Spoon, and during the past year a large tonnage was shipped from the property. At the present time, it is closed down, but it has been stated that operations will be resumed during the summer on a

larger scale than before. This indicates that the discovery in the tunnel was an important one, and adds materially to the possibilities of the deeper project from the Arkansas valley.

The strike at the Silver King property on Yankee hill is gradually growing in importance, and indications are that a strong ore-shoot will be discovered with continued development. The first shipment from the property will be made during the coming week.

UTAH

NEW MINE-TAX LAWS.—MINE LICENSES.—TAX ON NET PROCEEDS.—WORKMEN'S COMPENSATION ACT.—NET PROCEEDS OF MINES.—ELECTROLYTIC ZINC.—RADIUM MINING.

The legislature has finished its session and the mining industry now knows what it must face in the next two years. The income-tax bill was killed in the Senate after passing the House unanimously. Compensation and special-tax measures were passed. Prior to 1916 all property other than mines was taxed at 30 to 40% of its value, whereas mines paid taxes on their net proceeds, in addition to a valuation on the land and improvements. When in 1916 other property was assessed at full value, an attempt was made to assess mines at three times their net proceeds in addition to the other taxes, by means of an amendment to the constitution. That was overwhelmingly defeated at the polls. As a result the proportion of the total taxes derived from the mines was smaller than in preceding years. This, coupled with the war-time prosperity of the mines, engendered a feeling among representatives that some means should be found to make the mines bear as large a share of the burden of taxation as could be forced upon them, regardless of the lean years of the past. The failure of the constitutional amendment, and the fear that an attempt to apply the same method by statute would be declared unconstitutional, led to the enactment of another bill that seems no less discriminative and unconstitutional. It is called "An Act Providing for an Occupation and Privilege Tax on the Business and Occupation of Mining"; in other words, a license-tax aimed solely at the mining business, partaking of the form of an income tax. All persons, associations, and corporations engaged in the business of mining, as owners, operators, lessees, or lessors (employees and laborers alone excepted), unless location work or assessment work amounting to less than \$500 is being done, must pay a tax of \$1 each, plus 2% of the net proceeds of the mine. To make up for last year's deficiency the rate is to be 3% for this year. The mining companies are required to prepare complete statements of income and expense, in which all direct operating expense may be included except salaries of officials not on the mine. The usual penalty and forfeiture clauses are provided.

A constitutional amendment also is to be submitted to the voters providing that metal mines shall be assessed at \$5 per acre plus "some multiple or sub-multiple of the net annual proceeds thereof." All machinery and surface improvements would be assessed at full value. The State Board of Equalization is to be the assessing authority. All other mines, especially mines containing coal or hydro-carbons, are to be assessed at "full value." A compromise measure was passed at the end of the session providing workmen's compensation. State, mutual, and casualty insurance is provided, and financially responsible employers may carry their own insurance after satisfying the authorities as to their ability to meet the claims. Among the features of the new law are the following: "Employees may not pay dues into any company organized to provide compensation for injury or death; non-resident alien dependents are allowed but one-half the regular rate, with a maximum of \$1000; if the employer is not insured in the State fund, he must, in case there are no dependents, pay funeral expenses and \$750 into the State fund in cases of injury resulting in death; if death results within three years of the date of injury, the wholly dependent persons are to re-

ceive compensation at the rate of 55% of the average weekly wage, not exceeding \$15 per week, for a period of six years from the date of injury, but not less than \$2000 nor more than \$4500; benefits cover periods from 6 to 200 months; 10 days is the waiting period; medical aid not to exceed \$200 must be provided in cases of injury; a State Industrial Commission of three members, one of them the State Insurance Commissioner, is provided to administer the act; the offices of State Coal Mine Inspector and Commissioner of Immigration, Labor, and Statistics are under the jurisdiction of the Commission. In order to discourage litigation that might otherwise occur through a provision of the constitution that no statutes shall be passed depriving dependents of the right to sue an employer for injuries to a provider resulting in death, the Commission is given as full powers as possible to decide compensation-cases. Its denial of the right of the claimant to compensation on the ground that the injury was self-inflicted or that the accident happened out of and not in due course of employment, may be reviewed by the district court, and, on further appeal, by the Supreme Court of the State. Employers complying with the provisions of the act are not liable in damages for injuries not resulting in death. In case of death the dependents have the option of accepting the authorized compensation or suing in the courts, in which event all the common law defenses of the employer are made available. If dependents accept the provisions of the act, they are barred from any action at law, and, if they elect to try the case in the courts they cannot claim compensation under the act in the event of an unfavorable verdict. This law is regarded as one that fully protects the employee, without working hardship upon the employer, as would have been the case had the more radical proposals been incorporated.

The Ontario mine has won its taxation-suit. The county treasurer of Summit county had sued to collect taxes on an assessment of the Ontario drain-tunnel at full value, under the provision of the constitution that makes other property than the mine taxable at full value. The Supreme Court held that the tunnel was a necessary part of the mine and of no value except in connection therewith. Net proceeds of 54 mines, as reported to the State Board of Equalization, amount to \$38,299,516 in 1916. In this preliminary list are included 12 coal mines with total net proceeds of \$1,343,618; 15 Tintic mines, \$1,639,892; 8 Bingham mines, \$33,809,914; 2 Park City mines, \$257,183; 4 Stockton-Ophir mines, \$529,464; 3 Beaver county mines, \$87,194; 2 Cottonwood mines, \$402,161; and 4 mines producing asphaltum, gilsonite, and elaterite, \$116,565. The Park City sampling plant of the Utah Ore Sampling Co. has been dismantled and the business transferred to the enlarged plant at Murray. The Judge Smelting & Mining Co. has started the production of electrolytic zinc, but the exact production or the purity of the output has not been made public. The California-Comstock mines, connecting Park City with the Big Cottonwood districts, have been re-opened and development is proceeding on a large scale under new management. The property is well equipped with buildings and machinery. It was the scene of extensive development in earlier days, and several interesting geological problems now await solution. The Boston Development Co. has cut another large dike of granodiorite porphyry in the north-western part of the Maxfield mine in Big Cottonwood, and is driving both north-east and south-west seeking a favorable limestone bed in which to look for ore. The other large shoots of ore have been found near the porphyries that were cut in the eastern portion of the property. These pitched to the north-west. The company has expectations of finding another orebody in this part of the property where work is carried on 2200 ft. below the surface. Some good ore was found here in the early days. Fire in the stopes of the Utah-Apex at Bingham compelled withdrawal of the pumps so as to flood the mine. Over 400 men will be laid off for at least ninety days. The revival of the radium-mining industry that had been prophesied seems

to be near. The Consolidated Ores Co. has announced that work is to be resumed on its deposits near Moab, and other operators are expected shortly to resume.

JOHANNESBURG, TRANSVAAL

SUDDEN FLOOD OF WATER IN EAST RAND PROPRIETARY.—MINERAL OUTPUT OF SOUTH AFRICA IN 1916.—STATE MINING.

In a previous letter mention was made of a novel prospecting scheme at the East Rand Proprietary mines for proving the reef at a depth of 6000 ft. from the surface, at a point 2000 ft. south of the present workings, where development had given unsatisfactory results. The proposal was to drive a cross-cut from No. 27 level at a depth of 4000 ft. from the surface, for a distance of 2000 ft. and then sink 2000 ft. to the reef.

This cross-cut, however, had only just started when it tapped a body of water described as an underground river, the inrush of water being nearly 5,000,000 gal. in 24 hours. This is a great flow of water to be dealt with at a depth of 4000 ft., but with the concentration of the pumping-facilities, and by bailing in addition 1,000,000 gal. per day, the water was kept sufficiently under control to allow a bulkhead to be built at the entrance of the cross-cut. Even with a by-pass allowing a flow of 600,000 gal. of water per day, the pressure on the dam was 850 lb. per sq. in. Some of the water found its way into the incline shafts of the Angelo Deep, but the pumps responded well to the demand made upon them, otherwise the adjoining Hercules mine must have been flooded also. It was to obviate the water difficulty that the cross-cutting scheme was adopted, but this heavy in-flow of water came as a surprise, and it has become necessary to add to the pumping-facilities, which had been considered as adequate.

The total mineral production of South Africa reached last year a total value of £49,645,555, to which the Witwatersrand contributed in gold alone £38,094,786. The production of diamonds last year was 2,346,330 carats, valued at £5,582,976, being about the normal output, but at the present time all the diamond mines have resumed production, and this output is expected to reach a value of at least ten millions sterling. The coal output was 10,007,473 tons valued at £2,715,313, a record output, of which over 6,000,000 tons was produced in the Transvaal, and 3,000,000 tons in Natal. The total output of base minerals and metals other than coal, was valued at £1,751,184; copper, £1,132,140; and tin, £355,487, being the two largest items.

The tonnage milled by the Witwatersrand mines last year was 28,525,252 tons, as compared with 28,314,579 in the year 1915, and, considering the increased gold production, was more satisfactory than usual. The recovery per ton milled increased from 26s.3d. to 26s.8d., due probably to the increased tonnage from the Far East Rand mines that was milled during the year, where the value of the ore proved to be better than had been anticipated. Working costs increased from 17s.5d. to 18s.1d. per ton, due principally to increased cost of stores and allowances as a result of the War. Working-profits fell from £11,931,062 in 1915 to £11,630,001 in 1916, or from 8s.5d. to 8s.2d. per ton. These figures are exclusively those of the Rand and do not include the gold mines producing outside the Rand area, which during the year have fared badly.

The Far East Rand goldfield continues to attract attention, and now, that the Commission appointed to enquire into the Government working some of the areas has concluded the taking of evidence, its report is anticipated with interest. Since the Commission commenced its investigations, the controlling houses have shown a more ready disposition to tender for some of the Far East areas, probably because the conditions governing the tenders were made more elastic by the Government. Previously the conditions attached to the tenders were considered too rigid, and the minimum too high,

with the result that no tenders were submitted. It was this difficulty of obtaining tenders that led to the demand for a Government Commission to enquire into the advisability of the Government working the areas itself. However, as the recommendation of the Mines Department to ameliorate the conditions of tendering was adopted on the last occasion, the tenders handed in were more numerous, and the terms obtained by the Government as lessors were satisfactory. Providing similar terms can always be obtained by the Government the need for 'State mines' will not appear so pressing.

A variety of opinions has been expressed in the evidence submitted to the Commission as to the advisability of the Government adopting the principle of State mining. Some of the witnesses have expressed the opinion that the State ought to work the areas so as to receive the whole of the profits, no matter what tenders were submitted. Others recommended that only in the event of the Government failing to

A YOUNG MINE IN THE NORTHERN TRANSVAAL.

obtain suitable tenders should the question of State mining be considered. Other witnesses urged that it is the duty of the Government to do all it possibly could to induce the public to tender for the leases, even if it involved the prospecting of the areas and sinking shafts, before calling for tenders.

There is little doubt about the Far East Rand goldfield being of uncertain value. Dr. Mellor, as assistant director of the Geological Survey, put forward the view that the reef had been deposited in elongated patches with a south-east axis, and that where the reef is well developed and of fair thickness, it is generally profitable. Extensive areas occur where the reef is practically absent, the foot and hanging walls coming into contact in places. In his evidence before the State Mining Commission, Dr. Mellor recommended that the whole of the Far East Rand be prospected and proved before heavy expenditure in equipment or in working is incurred. At the last meeting of the Government Commission the Government engineer stated that if the Government went in for prospecting by sinking shafts before calling for tenders it might well go in for State mining. He also stated that in ten years' time he estimated that 27 of the existing producing mines will have been exhausted. As it takes eight to ten years to sink, develop, and equip these Far East Rand mining areas, it is evident that in a few years the output of the Rand must come to a standstill, if it does not decline, before some of these Far East Rand areas have become producing mines.

TORONTO, CANADA

IMPORTANT FINDINGS OF THE PROVINCIAL NICKEL COMMISSION.

LARGE ORE RESERVES AVAILABLE IN CANADA.—PLANS FOR REDUCTION AND REFINING.

The report of the Ontario Nickel Commission, which has been delayed for some time, owing to the illness of the chairman, George T. Holloway, of London, was presented to the Legislature on March 26. It is a document of 800 pages and covers practically every phase of the question. The commis-

sioners, or some of them, have visited the mines and works of the various nickel-producing countries in addition to making exhaustive investigations as to the present condition and possibilities of the Canadian nickel industry. The conclusion is that nickel can be economically refined in Ontario, and that owing to the extent and richness of the nickel deposits, the Province offers better facilities for the production of nickel at a low cost than any other country and has little to fear from competition. They report that while any of the processes now in use for refining could be successfully worked in Ontario, the most satisfactory method will be the electrolytic, in view of the facts that no chemicals are required, that it effects a greater saving of the precious metals, and that electric power is cheap and abundant. It is noted that the projected refinery of the British America Nickel Corporation, which will probably be placed near the Murray mine, in the Sudbury district, will use the electrolytic or Hybinette process. The drastic proposals to secure the refining of the entire Ontario output of nickel within the Province finds no favor with the Commission. They point out that the Provisional Legislature has no power to accomplish this directly by prohibiting the export of the ore, or imposing an export-tax, and that there is a grave doubt as to whether it would have authority to impose differential taxation in favor of the home-manufactured product. Government ownership would be impracticable, as it would cost about \$100,000,000 to expropriate the deposits and plants of the Sudbury district. The view is expressed that the completion and operation of the two plants now arranged for will go far toward a solution of the question of domestic production, and that the output of these refineries, together with the nickel now produced in Britain from Sudbury matte, will fully meet the requirements of the British Empire. The geology and mineralogy of the Sudbury nickel deposits is fully described, and the extent of the proved ore-reserves is estimated at 70,000,000 tons, while, if the probable and possible ore were included, there would be an aggregate of 150,000,000 tons. The present method of taxation on net profits is regarded as just and equitable and any change should be an increase of the rate rather than a change in principle, but the present rate of 3% should not be raised above 5%. The method in vogue of ascertaining the value of nickel-copper ore at the pits is not considered satisfactory. The profits to be taxed, it is recommended, should be fixed on the basis of the value of the refined product, less deductions, as at present, and such further deductions for the cost of actual treatment as can be established by the owner to the satisfaction of the mine assessor. The report is silent as to the charge that the International company has escaped with a very light tax contribution in the past, and contains no suggestion for the retro-active taxation measure promised by Hon. G. Howard Ferguson, Minister of Mines.

The 4-weekly statement of the Hollinger Consolidated for the period ended February 25, shows gross profits of \$210,868, from the treatment of 48,252 tons of ore of the average value of \$8.45 per ton, at a working cost of \$3.96 per ton milled. The mill ran 83% of the possible running time. Exaggerated statements of a very rich find on the Acme property that have been published have been denied by the management. It appears, however, that a vein on the 425-ft. level has been yielding some exceptionally rich ore, but the discovery is not a new one. At the McIntyre the main vein has been driven on for 900 ft. on the 1000-ft. level, the drift being in ore all the way. Cross-cutting at intervals shows that the orebody averages 28 ft. wide. The drift will be continued toward the Plenaurnum property, which is under option to the McIntyre, and explorations made. The shaft of the Jupiter, now down about 500 ft., is being continued to the 1000-ft. level. A diamond-drill hole on the east end of the Jupiter has cut a 5-ft. vein of high-grade ore at a depth of 735 ft. Harry Darling has resigned as manager of the Dome Lake and has gone to California on behalf of the Crown Reserve Company.

Now that Kirkland Lake district is obtaining a supply of electric-power, development is making rapid progress. The annual report of the Tough-Oakes shows earnings from production amounting to \$707,114 from the treatment of 39,863 tons of ore. Dividends amounting to \$365,235 were paid, and operating expenses were \$328,066. The deficit was increased to \$104,567. This unsatisfactory condition was due to the curtailment of operations for want of power. Some rich ore has been developed at the Hunton-Kirkland, where a vein 7 ft. wide has been stripped for 200 ft. The shaft is in high-grade ore for 18 ft. At the Wright-Hargraves, No. 2 shaft has reached the 100-ft. level and will be continued to the depth of 300 ft. It is in high-grade ore. At the Kirkland Lake, the vein at the 500-ft. level is stated to be from 20 to 30 ft. wide and richer than on the upper levels. The shaft is being put down to the 600-ft. level.

The main shaft of the Temiskaming has reached the 1600-ft. level and has been connected with the workings of the Beaver.

CRIPPLE CREEK, COLORADO

THE DISTRICT NOW PRODUCING OVER A MILLION A MONTH.—DEEP MINING FROM THE ROOSEVELT TUNNEL.

The production from the mines of the Cripple Creek district for the month of March, as reported by the mills and smelters, was as follows:

	Tons	Value per ton	Total value
Golden Cycle M. & R. Co.....	34,000	\$20.00	\$680,000.00
Portland G. M. Co.....	10,367	17.08	177,068.36
Smelters, Denver and Pueblo...	2,500	55.00	137,500.00
Portland, Victor	18,600	2.34	43,524.00
Isabella Mines Co.....	1,600	3.00	4,800.00
Worcester-Ruble mill	400	2.90	1,160.00
Gross value	67,467		\$1,044,052.36
Average value per ton, \$15.47.			

A new company composed of Chicago and Denver men recently has been organized to operate the properties of the Last Dollar Gold Mining Co. on Bull hill. The new company will be known as the Catherine Gold Mining Co. Charles Walden, of Victor, will be manager.

The Vindicator Gold Mining Co. has men at work constructing dams in Grassy gulch to impound the tailing from the new flotation-plant. Some of the slime has already escaped into West Beaver creek and ranchers in that vicinity are contemplating damage suits against the company to force the latter to keep its tailing where it belongs.

Negotiations are under way between the Raven & Beacon Hill Gold Mining Co. and the Elkton Con. M. & M. Co., looking to the exploitation of the estate of the Raven & Beacon Hill G. M. Co. from the Roosevelt-tunnel level of the Elkton shaft.

Dividend 54 of the Cresson Con. G. M. & Dev. Co. will be paid April 10. The amount of the dividend is \$122,000 and the total paid by the company will be \$4,709,162.56.

It is expected by the middle of April the new Independence mill of the Portland Gold Mining Co. will resume the treatment of low-grade ores.

On March 26 the American Smelting & Refining Co. officially announced a reduction in treatment-rates on ores from the Cripple Creek district. The new rates become effective immediately, and are as follows:

Ore to the value of \$30 per ton, \$5, including freight and treatment.

Ore of value between \$30 to \$40 per ton, \$5.50, including freight and treatment.

Ore of a value in excess of \$40 per ton, \$6, including freight and treatment. This means a reduction of from \$1.50 to \$2 per ton.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

(Special Correspondence.)—Forty-five men are blocking out ore in the Willow Creek district for the early spring run and teams are busy hauling mining timbers and supplies to the mines; recently the Talkeetna Mining Co. landed its new mill at the mines.—The new town Wassilla, on the main line of the Government railroad, will be the supply station for the Willow Creek mining district the coming season, being only 15 miles from the mines.

Knik, March 1.

TOLAVANA

At the beginning of its third year this camp is showing great activity. "From No. 2 Below Discovery, to No. 21 Above, the pay-channel has been proved on the third-tier bench, right limit of Livengood creek, and there are about 50 plants hoisting pay-gravel. There is also some work being done on creek-claims, on the upper end of the flats, Below Discovery, the Keystone drill is again in operation after recovering the bit which was stuck 140 ft. from the surface and which had to be dug out. Pay has been found on all of the left-limit tributaries of Livengood creek from Good-luck gulch, near the head to Lillian creek at the lower end, with Amle, Gertrude, and Ruth creeks between—five creeks in all. Considerable prospecting is also being done on Goldstream and other tributaries of Mike Hess creek, where good prospects are being found, but so far no pay has been discovered. Across the ridge, on the Tolovana river, right-limit, is Olive creek, which has been producing the past two seasons, but will be worked more extensively this season, as Jim Hudson has recently discovered pay-gravel 40 ft. thick. The next creek up-stream is Esther, where pay has also recently been found. Near the heads of Ruth, Olive, and Lillian creeks, C. E. Lang and C. A. Frank are developing a group of lode-claims. They have traced the lode over a mile and get good pannings—some of them high—across a width of 600 to 700 ft., but so far they have not found either wall. All things considered, the district looks good and there is still room for a large increase in its size, as many of the adjacent creeks that show good prospects have by no means been thoroughly prospected.

ARIZONA

MOHAVE COUNTY

(Special Correspondence.)—Negotiations are under way for a consolidation of the Big Jim and Tom Reed mines, or the purchase of the former by the latter on a basis of exchange of stock. There has been some ill feeling between the two companies and some talk of extra-lateral rights on the part of the Tom Reed. It is said, however, that an agreement has been reached to arbitrate the apex-claims if a consolidation is not effected.

Ore assaying \$4.90 to \$13.60 per ton across 6 ft. has been struck in the Telluride property at a depth of 535 ft. On the level 60 ft. above, the vein is practically barren. The shaft is being sunk to 600 ft. where still better ore is expected. The property is on the south side of the easterly end of the Tom Reed mine, where ore has been developed for 1100 ft. J. H. McIver, who opened-up the United Eastern, is in charge of operations.—The United Eastern gives the following as the production of that mine for January and February: The mill started January 4. Inclement weather hindered work and resulted in a low extraction, 92.8% for the month; 3800

tons of ore was milled of an average value of \$21.86 per ton, with a gross recovery of \$83,089.58. Conditions improved in February, and the extraction was 95.2% from 5383 tons, averaging \$22.33 per ton, realizing \$120,176.36. Unofficial reports give the daily output for March at \$5500.—The Adams east drift on the 400-ft. level is in low-grade ore 210 ft. from the main cross-cut. The company expected to cut the downward extension of an ore-shoot at about 220 ft.—Connection has been made between the Big Jim and the Aztec workings on the Tom Reed at a depth of 400 ft. Both companies are in ore of excellent grade at the point of connection. The foot-wall drift on the 600-ft. level of the Big Jim is in 150 ft. The average for the first 70 ft. was \$18.14. Superintendent Keating reports the same grade of ore throughout. At 100 ft. in the drift a cross-cut was driven to the hanging wall. The vein is 35 ft. wide.—The annual stockholders' meeting of the Tom Reed Gold Mines Co. has been postponed from March 31 to April 30. It is understood that important matters, not yet settled, will be taken up by the directors before the date of the meeting. Machinery for the addition to the mill is being installed and the company expects to have the plant in operation within thirty days.

Oatman, April 2.

(Special Correspondence.)—Secretary Warmbath, of the Big Jim Gold Mining Co. has wired as follows: "United Eastern this afternoon bought the Big Jim and Monarch claims of the Big Jim company, paying for the same with United Eastern treasury stock. Full details will be given as soon as the deal is completed." The United Eastern report of December 11, 1916, showed 300,000 shares in the treasury. The company is producing over \$150,000 monthly. Big Jim is credited with ore estimated at \$2,500,000 exclusive of that on the 600-ft. level recently opened. Both mines are on the same lode, though one mile apart.

Oatman, April 4.

(Special Correspondence.)—An experienced flotation-man has been employed by the United States Smelting, Refining & Mining Co., stationed at the company's smelter at Needles. He is engaged in experimental work on ore from the company's Gold Road mine, five tons of ore having been sent to the smelter last week. The mine is equipped with a 300-ton cyanide-mill, which has been idle since July 1, 1916.

Oatman, April 3.

YUMA COUNTY

The steamer 'Iola' recently brought the first consignment of ore from the mines of the Western Arizona Copper Co. and unloaded it on the river bank near the Santa Fe railroad bridge at Parker. The ore carries about 12% copper and \$4 gold per ton. This ore was sorted from the run-of-mine rock taken out in driving an adit, which was in 60 ft. April 1. The adit follows the foot-wall of a vein, shown to be 20 ft. wide by cross-cutting. It is expected regular shipments will be made.—The Copper Basin shaft is down 300 ft. Sulphide copper ore was found at 90 ft. depth, where the first sign of water appeared. Since then the influx of water has steadily increased and now amounts to 2500 gal. daily. Pumps have been ordered.—A churn-drill for the Mammoth has arrived at the mine, and will be employed in prospecting the ground before the site for the proposed 3-compartment shaft is chosen. There is stated to be 20,000 tons of ore on the dumps, and shipments are to be made.

CALIFORNIA

Development work in the California oilfields during the first quarter of 1917, as shown by the reports of the State Mining Bureau, amounts to twice that done during the corresponding period last year. This year there have been 287 new wells started. The other work passed on by the Bureau engineers, such as tests of water shut-off, deepening, re-drilling, and abandoning wells, has increased in like proportion. Statistics indicate that the present rate of production for the average well is slightly lower than it was during the past year, which, in conjunction with the constantly decreasing stock of stored oil indicates no immediate cessation of drilling activity. The price of crude oil at the wells averages about 40% higher than it was a year ago. The cost of material and labor in the fields has also advanced nearly as much. The report for the week ended March 31 shows 17 new wells, 27 tests of water shut-off, 25 deepening or re-drilling, and 6 abandoned.

EL DORADO COUNTY

GARDEN VALLEY. The Cincinnati mine, $1\frac{1}{2}$ miles south of Garden Valley, has been under development for some time by San Francisco and Berkeley owners. An adit is now in 200 ft. on the foot-wall of the vein. The widest part of the vein from which assay-samples were taken was 60 ft. between walls. The average value of the ore was \$1.65 gold per ton. A width of 12 ft. gave average returns of \$5.17 free gold, and 2 ft. on the hanging wall averaged \$114.19. A cross-cut at the 150-ft. station in the tunnel shows 16 ft. of good average pay-ore; and a cross-cut at the 200-ft. station, at a vertical depth of 80 ft., shows a body of dry decomposed yellowish ore 11 ft. wide that averages \$8 free gold per ton and also contains a fair average of high-grade sulphides. The vein extends 2000 ft. on the Cincinnati, running east-west across the formation.

INYO COUNTY

Work is moving along on the plant of the California Alkali Co., at the south-west corner of Owens lake, says the *Inyo Register*. The frame-work of some of the buildings is up. The plant will have excellent shipping facilities, its nearness to the railroad avoiding the transshipment necessary for the plants situated on the east side of the lake. The Foundation Company, of San Francisco, has the contract. A fourth plant is a possibility. Porfirio P. Garcia, of San Antonio, Texas, was recently at the lake with assayers and chemists, and shipped a carload of the alkaline deposit and a quantity of lake water to an Eastern point for analyses.

MARIPOSA COUNTY

Rudolph Schweitzer and a partner, who for two years have been working a mine on the Mariposa Grant, the property of the Mariposa Mining & Commercial Co., report finding very rich gold ore in their lease, and that to keep the discovery a secret and secure, on April 3 they placed a heavy door in the tunnel. The following morning when the men returned to work the ore had all been stolen. Mr. Schweitzer says that not less than a ton of the quartz, worth \$10 per pound, had been taken, thus losing \$20,000.

MONO COUNTY

(Special Correspondence.)—The Masonic district is again displaying activity after several years of quiet, with the outlook favorable for a brisk summer. At the Serita, operated by the Serita Mining Co., controlled by Stall Bros., 60 to 75 men are constantly employed. Ore is sent to the Pittsburg-Liberty 10-stamp mill, which was acquired by the Serita Co. last year and tube-mills added to the cyanide department. Rich ore is said to have been found recently in the east vein. This property, composed of the Serita, Serita No. 1, Bull Moose, and Friday claims, has yielded well in the past year. Mine and mill equipment is operated by electricity, the power-plant being owned by the company.

John D. Martin and associates of San Francisco are working the New York group, adjoining the Serita. The main shaft is down 190 ft., but work is chiefly confined to the 150-ft. level, where a wide vein of good ore is exposed. The pump is operated by a gasoline-engine. The same people have taken a bond on the Snowshoe claim.

The Lakeview property has been taken under bond by E. C. Easton, of San Francisco, and preparations have been made for vigorous work.—Conway & Fredericks, formerly of Sweetwater, Nevada, are working the Pittsburg-Liberty under bond and lease. Ore indications are reported encouraging, and it is planned to carry the workings deeper in hope of again finding the main orebody.

The Masonic Mines Association has arranged for work on a large group of claims, under the management of George Burris. A double-compartment shaft will be sunk 200 ft. to intersect the Masonic lode, which is believed to pass through the property.—The Sally Degner claim is being worked on lease by Hayes brothers.

Masonic, April 7.

PLACER COUNTY

(Special Correspondence.)—Recent development work on the Morgan asbestos mine, at Lover's Leap, on the middle fork of American river, has resulted in the discovery of a large vein of long fibre (slip-fibre) asbestos. The company is to be re-organized and suitable machinery provided to prepare the mineral for market. Mr. Werner is in charge.

Towle, March 26.

SHASTA COUNTY

(Special Correspondence.)—The Bully Hill group of copper properties, near De Lamar, is being re-opened by Eastern capitalists, under the management of Walter Arnstein. The group comprises 23 claims. The development has been mostly in the Bully Hill, Winthrop, Rising Star, and Baxter mines. The Bully Hill has been opened by a 1000-ft. adit and 800-ft. three-compartment shaft, the latter sunk from the adit 900 ft. from the portal. This shaft is equipped with a double-drum electric hoist and two electric plunger-pumps with a capacity of 700 gal. of water per minute. The Rising Star mine has been opened to a depth of 800 ft. by a three-compartment shaft and is well equipped. When last operated, six years ago, the property was producing approximately 5,000,000 lb. of copper per annum. Work was discontinued because of the high zinc content of the ore, and also trouble with Federal authorities over smelter-smoke. With the ordinary blast-furnace smelting, Captain De Lamar estimated the daily loss by waste of the zinc at approximately \$1000. The company recently perfected an electrolytic process for extracting the zinc, leaving copper, gold, and silver to be recovered by smelting. The zinc-process is embodied in the \$350,000 electrolytic plant recently completed near Kennett by the Mammoth Copper Co. The old smelter has two blast-furnaces, of 350 to 400 tons daily capacity, McDougall roasters, a reverberatory-furnace, and converting-plant. It is reported that the new management plans the building of an electrolytic zinc-plant, and that flotation equipment may also be provided.

The Arps Copper Co. has started work near the Baxter mine of the Bully Hill group. In addition to the copper-bearing ore, silver ore has been lately discovered, and plans are being made to open the mine to greater depth and install more equipment. Superintendent Henry states that shipments of selected ore will be made regularly to the Mammoth smelter until the company installs a flotation-equipment.

A lower adit is being driven at the Shasta Belmont, near the Arps, and the management expects to reach the main orebody within 100 ft. Ore will be shipped to the Mammoth smelter until the company can provide a flotation-unit. Negotiations are proceeding for the bonding of the property to a company of Eastern people.

It is stated at Ingot that operations will be resumed at the

Afterthought copper mine within 60 days, and that plans have been arranged for construction of a large flotation-plant, to cost approximately \$100,000. The railroad from Bella Vista to Anderson is being placed in shape for shipment of ore and supplies. Miners have been re-timbering the workings. Leaching-equipment will probably be provided to handle the zinc-bearing ores, of which a large tonnage is exposed.

Reading, April 6.

SISKIYOU COUNTY

(Special Correspondence.)—The Mason Valley Mines Co. has constructed a camp at the Gray Eagle property, near Happy Camp, improved the roads, and otherwise arranged for large-scale work. Mine developments are said to be satisfactory, and shipments will be made this spring to the smelter near Thompson, Nevada. It is stated the company plans to erect flotation-equipment at the mine, which contains upward of 4,000,000 tons of ore. Several nearby properties have been taken under option and are receiving attention.

Recent reports that the Blue Ledge Copper Co. was planning immediate work at its mines in the northern part of this county appears to be erroneous. Until a railroad is extended into that district transportation problems heavily handicap production. A line has been surveyed to Medford, Oregon, and may be built this summer. Should this be done the Blue Ledge district promises to become one of the most active copper regions of the West, as large deposits of fair-grade ore has been discovered there.

Yreka, April 5.

TUOLUMNE COUNTY

(Special Correspondence.)—Taxes for seven years, amounting to \$6000 on the Clio group of mines, were paid and title to the property passed to Minnie Grauer, of Oakland. The transfer was first made by the Ora Mining Co. to Otto G. Freyer-muth, of San Francisco, who deeded the property to M. Grauer. It is said that operations will be resumed under the direction of Robert Grauer, who has spent much time in recent years in exploring the property.

The Rawhide mine will soon have been unwatered to the bottom. While the water was being pumped out, levels were being cleaned and repaired, and as a result exploration and mining work will not much longer be delayed.

It is reported that good ore has been discovered in the Confidence mine, 12 miles east of Sonora, operated by the Confidence Mines Corporation, recently organized under the laws of Virginia. The mine was re-opened during the latter part of last year, and has been equipped with machinery for development.

A gasoline-engine and an air-compressor have been installed at the mine on the Soulsby ranch being operated by Harris, Moore & Baker. The stoping from the rich shoot lately found will begin soon.

A vein 8 to 16 ft. wide, just west of Sonora, is being prospected by C. E. Rives. Several shafts, the deepest 125 ft., have been sunk on the vein and good ore has been found in each. At the south end, where the vein is 16 ft., it is stated assays show an average of \$5.70 per ton. A streak a few inches wide goes as high as \$96 per ton. About the middle of the property the vein is 8 ft. wide and the assays run up to \$16. On the north end, at a depth of 20 ft., there is 6 ft. of quartz. No assays have been made of the ore at this point.

Work has been resumed at the Addis mine, near Confidence.

Mining for chrome and magnesite is becoming an important industry near Chinese. All the chrome ore that can be mined on the property of Simon Goudge and George Egling during a period of 12 months has been contracted for, and shipments are being made from other properties also.

Sonora, April 4.

COLORADO

A meeting of all tungsten operators and others concerned in the industry will be held in Denver in the rooms of the

State Mining Commission, for the purpose of furthering interest in the bill that was introduced by Congressman Timberlake, providing for a tariff on tungsten and which he now has support enough to pass should an extra session of Congress be called. According to word from Congressman Timberlake, the bill now has the support of California, Arizona, Pennsylvania, New Mexico, and New York, besides a scattered support from other States.

The tungsten miners declare they will be forced to close their mines should the War end and the embargo on shipping be declared off. The industry is now producing thousands for Western States, they say, and should be protected until the place is reached where the mines of this country can compete in efficiency and low-cost production with other countries. The tariff asked by Congressman Timberlake's bill is \$10 per ton on the ore and \$1.25 per pound on the finished product. This tariff, they assert, would enable them to compete with foreign products and keep open their mines, even though the present price of tungsten were reduced materially.

Naturally, in the event that the United States takes the sweeping steps planned for preparedness, tungsten will become one of the most important products in the entire West and the tungsten miners declare their properties are capable of wide development.

The meeting of the operators will be held in a few weeks.

IDAHO

SHOSHONE COUNTY

Greater milling capacity than was first contemplated and an expenditure of \$200,000 or more is proposed by the Nabob Consolidated Mining Co., at Wallace, according to H. T. Irvine. The intention to erect a concentrating-plant having a capacity of 200 tons or more daily was announced several weeks ago. It was stated then that Manager Beaudry of the Stewart company was gathering a large quantity of machinery and materials of which use would be made promptly after the transfer in equipping the Nabob property.

It is probable that a sorting-plant will be established at once on the Denver section of the Nabob property to take advantage of current prices for the metals, says the *Spokesman Review*. The concentrating mill should be in operation within three months. In the meantime an important output can be made from the new workings, while development of the resources there, already large, is proceeding. An advance of the lower Nabob adit to the Denver claim, which would be penetrated at great depth, is among the projects.

A party of 15 students and instructors is visiting the Bunker Hill & Sullivan mine, mill, and smelter at Kellogg, and several of the mines and mills in the neighborhood of Wallace and Mullan. This is the annual spring excursion of the college of mines of the University of Washington.

MISSOURI

JASPER COUNTY

The production of lead, blende, and calamine of the zinc-lead mines of south-west Missouri and the adjacent field in Kansas and Oklahoma in 1916 was \$34,961,993, and the total production of the region since its discovery has reached \$328,453,558. In 1915 the production was \$26,038,650.

MONTANA

FERGUS COUNTY

(Special Correspondence.)—At Hanover 150 men have been employed all winter by the Three Forks Portland Cement Co. A 24-room hotel, large office building, and two apartment-houses have been finished and work has started on a number of store-buildings. A reservoir and water-system to supply water to the town and the plant are nearly completed. A complete machine-shop and store-room is about finished and will

be equipped with machinery in time to hasten construction of the cement-mill on which work will be started at once. Besides the deposits of limestone, shale, and gypsum near Hanover, there is plenty of sand-rock, brick-clay, and gravel for construction work.

There is still much snow in the mountains and many prospectors and miners are waiting for the snow to melt before reopening their properties.

In the Little Belt mountains zinc ore is being produced regularly at the Neihart mines and shipped to Great Falls. The Butte & Great Falls is among the shippers. Some copper and zinc ore is also being produced on Wolf creek, where a dozen men have been doing development work all winter. Shipments of ore are expected to be made from some of the old mines in the Castle mountains this summer.

In the Cumberland mine, at Maiden, the lessees have been sinking a shaft. Some good ore has been found during this development, but a strong flow of water was encountered that has flooded the mine. A pump will be installed as soon as possible and a drift will be run on the ore as soon as the water can be controlled.

Lewistown, April 3.

NEVADA

CLARK COUNTY

(Special Correspondence.)—The main cross-cut tunnel at the Yellow Pine mine has reached a point below the ore deposit on the 300 north sub-level, 1000 ft. from the portal. Connections have been established and all ore from the upper levels is now handled through the tunnel. The company has resumed production and plans to increase its output, also to ship from the Charleston property. Fred A. Hale, Jr., is manager.

The Hoosier lead-zinc mine has been sold to E. S. Armstrong and associates of Pasadena, California, for approximately \$40,000 by Harry Josephs and Claudia Morris, of Salt Lake City. It is planned to install a dry-concentrating plant, as a large tonnage of good ore is blocked out. N. Touroff has been appointed superintendent.

Ore running high in copper and cobalt has been uncovered at a depth of 60 ft. in the Red Streak claim, owned by N. B. Price and worked under lease by Smith Bros. The discovery was made in a winze from the old adit. A new lower adit will be driven. The Yellow Pine Co. has leased its Porter and Prospect claims, in the southern end of the district, to R. C. Lochridge, who has started work with Phil Ryan in charge. The claims yielded some rich lead-zinc ore ten years ago, but have been given little attention of late.

C. L. Hyde, of San Diego, California, has started work on the Milford group and expects to begin shipping to custom plants by way of Roach, the nearest railroad point. The Milford adjoins the Ingomar and has produced much shipping ore.—Important discoveries have been reported in the past week from the Boss Extension, Ironsides, and Paymaster properties. Goodsprings, April 4.

ESMERALDA COUNTY

(Special Correspondence.)—The flotation-plant of the Goldfield Consolidated is extracting 90% of the gold content of ore, and practically all the copper, according to general manager J. W. Hutchinson. The copper concentrate is sent to smelters, and the gold-silver concentrate is treated in the local refinery of the company. Hereafter the company plans to treat 500 tons of oxidized ore daily with cyanide, and 500 tons of sulphide by flotation. In addition to the Consolidated product, considerable custom ore will be handled, a contract having been recently signed to treat 100 tons daily for the Atlanta Co. It is officially stated that ore conditions in the Aurora Consolidated property are improving, and that this mine is earning profits. Several properties are being examined with a view to their purchase.

Ore shipments from the Atlanta in February totaled 250 tons,

with returns defraying all operating costs. The ore was drawn from the 1750-ft. level of the Merger shaft, where a 5-ft. vein of \$30 smelting ore is under development. It is intended gradually to increase the output of smelting ore, and to start the delivery of 100 tons of \$15 to \$20 ore per day to the Goldfield Consolidated flotation-plant.

Control of the Manhattan Mustang mine, at Manhattan, has been obtained by L. K. Koontz of Goldfield, and his Nevada and Eastern associates. Work on company account will soon start. The Train-Chase lease has been operating on the Mustang for two years, in which time \$35,000 has been extracted. The lease is well equipped and plans for work on a broader scale have been considered. The Koontz people are heavily interested in the Big Four and Morning Glory, two prominent Manhattan mines.

The Nevada Douglas Copper Co. is shipping three carloads of ore daily to smelters, from which about \$60,000 per month net is said to be realized. Capacity of the leaching-plant is being forced to 250 tons per day, the ore treated averaging close to 3%. The output of smelting ore will be increased as soon as the second furnace of the Mason Valley smelter is blown in.

Goldfield, April 8.

(Special Correspondence.)—The Goldfield Consolidated company reports for February as follows: Ore milled 21,000 tons, for \$19,220.98. Development work, 1698 ft. at a cost of \$5.53 per foot.

The operating costs were as follows:

	Per ton ore handled	Per ton total ore
Mining:		
Stopping	\$ 2.503	
Development	23.396	
Total mining	\$ 2.921	\$2.787
Leasing expense	9.741	0.050
Dump moving	0.508	0.019
Tailing dump moving	0.135
Transportation	0.086	0.086
Milling	2.274	2.274
Marketing	0.029	0.029
General expense	0.414	0.414
Bullion tax	0.028	0.028
Filter royalty	0.050	0.050
Flotation royalty	0.057	0.057
Surface	0.064	0.064
Total operating costs		\$5.858
Miscellaneous earnings		0.113
Net operating costs.....		\$5.745
Construction
Net costs		\$5.745

During February, lessees produced 108 dry tons of ore having a gross value of \$2696.02, of which the company received \$1531.16.

Goldfield, April 5.

HUMBOLDT COUNTY

(Special Correspondence.)—The contract for the 300-ton mill of the Rochester Combined Mines Co. has been let to K. Freitag, 1008 Hobart building, San Francisco, who will have charge of mill construction. J. W. Wilkey is general manager for the Combined Mines Co.—The capacity of the Packard mill will be increased to 150, and possibly 200 tons, daily before July. Jay A. Carpenter is in charge of the property.

The Nanzel Crown Point Mining Co. will begin construction of a 100-ton mill about May 1. It is reported that K. Freitag is to have the design of this mill. The office of the company is at Rochester.

Lower Rochester, March 26.

LYON COUNTY

A 600-ton sampler will be built at Hazen by the Western Ore Purchasing Co. to care for the large ore output of the State. F. M. Manson, manager for the company, states that plans are being considered for building the new plant. The company is now operating a 300-ton sampler at Hazen and the new plant will give the company a 900-ton daily capacity. The sampler will be equipped to handle all kinds of ore.

WASHOE COUNTY

(Special Correspondence.)—The Standard Metals Co. of Reno is sinking a shaft in this county on a vein containing good value in copper and silver. The shaft, which is vertical, is down 200 ft., and it is expected that the vein will be cut in 50 ft. more, when a station will be cut, and a drift started. Sinking will then be continued. A jack-head pump was placed in the shaft some time since, and for a while it handled the water readily, but lately the inflow of water has increased and the pump now is holding it until a heavier plant can be secured. The mine makes 100 gal. of water per minute, though a much larger quantity is anticipated in greater depth. The formation is grano-diorite and meta-andesite. The work is under the direction of John R. Meaker.

Reno, March 26.

NEW MEXICO

GRANT COUNTY

(Special Correspondence.)—The Calumet-New Mexico Mining Co. did 600 ft. of work during 1916, and has increased the working-force since the first of the year. Most of the work has been in or near the vein on the 200-ft. level, where a drift was run along 2½ ft. of ore the most of which carries zinc, lead, silver, and gold to the value of \$75 to \$100 per ton. It is intended to build a mill the coming summer. At present selected ore is being shipped.

Silver City, April 4.

(Special Correspondence.)—Carlisle Mining Co., at Steeple-rock, reports the Pilot mill operating at a capacity of 75 tons daily. The mill-heads average about 80c. per ton gold, 2 oz. silver, 1.25% copper, 7.5% lead, and 7% zinc. The lead and copper recovery is excellent, that of the zinc yet to be determined. The mill is producing regularly several tons of copper-lead concentrate, which assays \$8 per ton gold, 12 oz. silver, 10% copper, 50% lead, and 7% zinc. The property is now on an earning basis.

Steeple-rock, April 7.

SOCORRO COUNTY

(Special Correspondence.)—E. L. Starr, representing Dowst & Co., Inc., of New York, has made an inspection of the camp preliminary to underwriting a large block of the new securities issued by The Oaks Company.

The Mogollon Mines Co. is developing its 900-ft. level both west and east. The mill, on the night of March 29, was threatened by fire, started by a short-circuit in an electric-solution heater.

The Oaks Co. is increasing its crew at the Maud S. mine and is making a shipment of ore to a custom-mill. Work continues at both the Clifton and Eberle properties.

D. E. Bearup is meeting encouraging results in the development of his Eureka group in the west part of the district, both milling and high-grade shipping-ore being produced.

The local power interests of B. W. Hills and associates have been taken under option by Charles E. Stewart of New York, who proposes to complete the hydro-electric installation.

Mogollon, April 6.

NORTH CAROLINA

BUNCOMBE COUNTY

(Special Correspondence.)—At Sylva and Spruce Pine, the Harris Clay Co. operates kaolin mines successfully and is said

to be making money. C. J. Harris, of Sylva, North Carolina, is the owner of the enterprise. At Hewitts, Frank Hewitt, of Asheville, has mined talc for a number of years with success but his mines are reported to be so flooded with water that they cannot be operated longer successfully.—J. F. Conroy, of Sylva, is promoting some zinc and iron properties in East Tennessee.—The Carolina Barytes Co., of Stackhouse, and G. Anson Betts, have been interested in barytes mining at Stackhouse, but neither of these mines is in operation, though B. W. Gahagan is now operating his mines and shipping barytes.

The Shut-In Iron Mines, Inc., owned by G. Anson Betts, has just completed a hydraulic plant at Hot Springs, for the mining of brown iron ore.—The Marble Mining Co., of Marble, also owned by Mr. Betts, is installing a plant for the mining of iron ore.—The Gardner Hill Gold & Copper mine, near Greensboro, has been opened after an idleness of over 50 years.

Asheville, March 26.

OREGON

BAKER COUNTY

The Ben Harrison mine, 28 miles by road from Sumpter, is reported sold to E. H. Dewey, of Nampa, Idaho. The mine is near the head of Clear creek, at an elevation of 6500 ft. The vein has been stoped for 400 ft. above the 200-ft. level, and is said to have produced \$300,000. The ore is a mixture of sulphides in quartz—pyrite, chalcopryite, stibnite, and sphalerite, with silver sulphides, and gold. The value is uneven in its distribution. The machinery equipment consists of a gyratory-crusher, 20 stamps, a tube-mill, classifier, and Isbell concentrators.

JACKSON COUNTY

(Special Correspondence.)—The Cheney, Simmons, Ray and Haff group of quartz claims, three miles north-east of this city, have been operated by H. A. Ray and G. L. Haff the last two years. They were the owners of these properties excepting the Simmons and Cheney claims, which they operated under a lease from the owners. This property has been sold to Sacramento, California, people, who have been represented here by J. W. Davies, of that city. The consideration is stated to be \$80,000. The vein contains quartz carrying pyrite; this lode-matter contains gold and silver to the value of \$3 per ton. The high-grade ore occurs in boulders, at a depth of 80 to 100 ft. Sulphide ore begins to appear at 160 ft., and the vein is 5 ft. wide at 225 ft. depth. The hanging wall is a slate, and the foot-wall is limestone. The greatest depth attained on this vein is 600 ft., where it is 25 ft. wide. The discovery, in March 1916, of scheelite with the gold ore in this mine was announced. The mineral is a small stringer with quartz. Samples have been taken that run as high as 40% tungstic acid, but it is claimed by the management that the vein as a whole runs less than 2%. The discoverers of this vein, William Cox and George Lyman, two local miners, in 1896 mined a pay-shoot that netted them \$8000 in gold. This shoot occurred where a fault displaced the vein at a depth of 35 ft. Two years later they disposed of the claim to Elisha Ray, of this city, who began operations by driving 16 ft. and striking the continuation of the vein and removing a pay-shoot containing \$4800, at a depth of 25 ft. This claim has been owned and operated by the Ray family since that time, and they have realized various sums while developing the vein. Most of the permanent development work is on the Simmons and Cheney claims, which are generally known as the Sylvanite mine. The Sylvanite lessors, who were Canadians, fully equipped these two properties several years ago with a modern mill, hoists, and other machinery, all operated by electric power. Later, financial troubles caused the suspension of their operations, and the machinery was sold in the courts to satisfy their creditors. The new owners will start an adit at the foot of the hill and extend it to the vein, 1200 ft. This will give them a depth of 500 ft. Operations will begin at once with new ma-

chinery, operated by electric power. George Stone, recently of Colorado, will be general manager and G. L. Haff will be superintendent.

Gold Hill, April 3.

SOUTH DAKOTA

PENNINGTON COUNTY

Preliminary arrangements for starting work on the pipeline which will carry the water to the new hydro-electric generating plant of the Homestake Mining Co., soon to be erected in Spearfish canyon, have been made, says the Lead Call. For several days men connected with Frank G. Baum of San Francisco, electrical engineer in charge of the work, have been engaged in arranging for a camp headquarters in the canyon, and William B. Arndt, rock contractor of San Francisco, arrived recently to get his part of the work in progress at the earliest possible date. The Burlington station site at Maurice has been leased and will constitute the general headquarters of the construction people, while the pipeline work is in progress. The Homestake company has also leased the buildings of the Victoria Mining Co., to be used as camp quarters for the various crews of men employed on the job.

Mr. Arndt has the contract for driving one mile of tunnel and probably will be engaged for the entire job of grading, which will be practically all rock work, a distance of nearly 5 miles. The water will be conducted from the dam through a continuous wood-stave pipe, 52 in. diam., to the generating plant, where it will have a pressure of about 500 feet.

WASHINGTON

CHELAN COUNTY

The Lookout Mining & Milling Co. has uncovered a fine body of copper ore on its property in Methow valley, near Twisp.

FERRY COUNTY

(Special Correspondence.)—Since the resumption of operations in the Tom Thumb mine two weeks ago, the output of ore has been 550 tons. During the week ended March 29 the ore shipments from other mines were: Knob Hill, 230 tons, Lone Pine, by the Northport Smelting & Refining Co., 400 tons. The average output of the Knob Hill mine is now 30 tons or more daily. The Lucille Dreyfus mine, that for several years has been idle, is again in operation and putting out ore for shipment. The property is situated near Danville.

CANADA

PORCUPINE. The Hollinger, Acme, and the Consolidated Company (Hollinger Consolidated), has produced to December 31, 1916, \$15,466,444 and paid in dividends \$7,456,000. The deposits were discovered in 1909 and production began in 1911. The Hollinger output in 1911 was \$46,082.

HONDURAS

During 1916 the New York & Honduras Rosario Mining Co., at San Juancito, yielded an average of 150,600 oz. of silver and 1280 oz. of gold per month, from 10,565 tons of ore. The value averaged \$125,000. The December output was 11,600 tons for 182,000 oz. of silver and 1550 oz. of gold, valued at \$165,000. In 1915 the average monthly yields were 9815 tons, 145,659 oz. of silver, and 1267 oz. of gold, valued at \$97,125. Silver in 1915 realized 50.1c. per oz.; in 1916, 66.6 cents.

KOREA

The February clean-up of the Oriental Consolidated mines amounted to \$132,232.

TRINIDAD

The Trinidad Leaseholds (Ltd.) of London reports the oil production of the company for February at 4520 tons.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

JULES LABARTHE is at Juneau.

J. M. CALLOW was here this week.

MORTON WEBBER is at Grass Valley.

CHARLES BUTTERS has returned from New York.

GEORGE O. BRADLEY has returned from Salt Lake City.

GEORGE F. BRIDGER has gone to Baguio, Philippine Islands.

W. DEL. BENEDICT has returned from Monterey to San Francisco.

SPENCER C. BROWNE has returned to New York from California.

WALTER G. PERKINS has opened an office at 462 Mills building, San Francisco.

JAMES S. DOUGLAS, manager of the United Verde Extension mine, is at New York.

HERBERT STONE has joined J. M. HYDE and is in the Mills building, San Francisco.

MARK R. LAMB was in Oruro, Bolivia, recently; he expects to reach New York this month.

L. B. SPENCER & Co. have removed their laboratory from Hawthorne to Mina, Nevada.

H. E. DENNIE, is now Western manager for the Imperial Belting Co. at San Francisco.

T. A. RICKARD will deliver the Commencement address at the Colorado School of Mines on May 25.

WALTER KARBI-DAVIES and WILLIAM W. MEIN have opened an office in the Mills building, San Francisco.

J. F. MITCHELL-ROBERTS sails on the 'Tenyo Maru,' leaving San Francisco on April 12, returning to Korea.

T. D. REES, formerly with the Utah Copper Co., has joined the Stimpson Equipment Co. at Salt Lake City.

W. H. SEAGRAVE and W. T. DUNKLE have formed a partnership as consulting engineers at Seattle, Washington.

D. L. H. FORBES, recently construction engineer and metallurgist at the Chuquicamata mine, of the Chile Copper Co., has returned to New York.

FRANK C. LAURIE has been appointed general superintendent for the Freeport and Tampico Fuel-Oil Corporation, with headquarters at Tampico, Mexico.

E. R. JONES, until recently assistant superintendent of the Mass copper mine, has gone to Asbestos, Canada, to take a similar position with the Johns-Manville Company.

JESSE C. PORTER and JOHN B. STEWART are now in charge of the business of the C. L. Constant company of New York, in the National Bank building at Calle Cuba, Havana, Cuba.

FRED F. MELOCHE and STANLEY M. TIFFANY, who have been attending the last semester of the University of Washington, will leave for the north coast region of British Columbia on an exploring and prospecting tour.

HENRY J. GIFFORD is retiring from the superintendency of the Champion Reef mine, in India, and will be succeeded by C. F. HEATHCOTE, formerly manager of the Tasmania gold mine at Beaconsfield, in Tasmania.

F. G. CLAPP, managing geologist of the Associated Geological Engineers, has gone to Arkansas; M. L. FULLER, the other managing geologist, is making new explorations in West Virginia; C. T. GRISWOLD, geological engineer, is in southern Oklahoma; ERNEST MARQUARDT, geological engineer, in Wyoming; E. B. HOPKINS, geologist, has returned from Mexico to Texas.

THE METAL MARKET

METAL PRICES

San Francisco, April 10

Antimony, cents per pound	24
Electrolytic copper, cents per pound	38
Pig lead, cents per pound	9.25—10.25
Platinum, soft and hard metal, per ounce	\$105—111
Quicksilver, per flask of 75 lb.	115
Spelter, cents per pound	12
Tin, cents per pound	50
Zinc-dust, cents per pound	18—20

ORE PRICES

San Francisco, April 10

Antimony, 50% metal, per unit	\$2.00
Chrome, 40% and over, f.o.b. cars California, per ton	18.00—20.00
Magnetite, crude, per ton	8.00—10.00
Tungsten, 60% WO ₃ , per unit	16.50—18.00
Molybdenite, per unit for MoS ₂ contained	40.00
Manganese, 50% (under 35% metal not desired)	29.00
Manganese ore, 40 to 45%, sells f.o.b. Chicago at 58c. per unit with a penalty of 50c. per unit for more than 8% silica.	

Tungsten: The past week has shown further great activity in the tungsten market, which, however, becomes more and more difficult on account of the many demands by buyers for guarantees against impurities, and only well-known marks that have reached this market continuously of approximately the same quality can be readily sold at the top prices. Other marks can only be sold at concessions, and therefore it will be found that the prices for tungsten ore range, according to degree, from \$18 per unit for high-grade wolframite and scheelite down to \$16.50 for material that, on account of impurities, has only a limited market. A large amount of business has again been done for home consumption. France and Italy have been in the market. Besides, forward material has had ready buyers and it was impossible to fill an order for 100 tons of spot delivery wolframite, as such a quantity was not available for prompt delivery. The prospects for the market are good and present prices should be maintained.

EASTERN METAL MARKET

(By wire from New York)

April 10.—Copper is weak and dull. Lead remains unchanged at 9.35c. Zinc is slightly lower, at 10.50c. Platinum is unchanged at \$105 to \$111.

The Standard Silver-Lead Mining Co. has declared a quarterly dividend of 5c. per share, payable April 15 to stock of record March 31, putting the stock on a 20% annual dividend basis. From September 1915 until December 10, 1916, when last monthly payment was made, the company paid a regular dividend of 2½c. per month, or 30% per annum.

Heavy buying of silver on United States Government account has played no small part in the recent recovery in price of the white metal.

May	39.28	49.10		Nov.	39.50	44.12	
June	40.26	42.07		Dec.	38.71	42.55	

The tin market continues on the advance with difficulties in getting quotations from the other side. Prices have now reached 56½ to 57c per pound for spot delivery and the prospects are that these high prices will be maintained for some time to come.

ANTIMONY

In New York spot antimony (metal) is scarce and quoted at 35c. This is extraordinary as material now afloat since February and due any time in New York is obtainable at 20c. April-May shipment can be had at 13½c. per lb., and this wide margin between spot and forward must soon disappear, as it is an unhealthy condition. Needle antimony is offered for forward delivery around 8½c. per pound, but there has been no business during the past week. Antimony ore remains as scarce as ever and no business is reported though inquiries are in the market from many quarters.

PLATINUM

Platinum remains unchanged at \$105 per oz. for soft metal and \$111 for hard.

Eastern Metal Market

New York, April 4.

International and national uncertainties continue to dominate the entire metal market and to cause a waiting attitude by all concerned. Until a definite policy is adopted by the Government there can be no clarity to the market nor much activity. Buying is only spasmodic and based on actual needs.

Copper is inactive and weaker with declining prices.

Zinc continues lifeless and stagnant with prices practically unchanged.

Lead is firmer than most of the leading metals but the market is dull and at a standstill.

Tin continues strong and is firmly controlled, though it too is inactive and lower.

Antimony is still scarce and nominally higher.

The absorbing topic in the steel-market is the amount of steel the producers are to sell to the United States Government and particularly the price. There will be no 50% reduction from present levels, as in the copper deal, because cost prices are proportionately much higher and some steel-makers would lose money on such an arrangement. The problem is not a simple one. A steel-plate price of 3c. instead of 6c. would mean a fraction of a cent above cost to a mill paying \$35 per ton for basic pig-iron. March exceeded any month since November, 1916, in pig-iron output, the total having been 3,250,757 tons, or 104,862 tons per day, compared with 94,473 tons per day in February. Many steel and pig-iron prices continue to advance.

COPPER

The uncertainty in international and political affairs has halted transactions to such an extent that the market is dull and inactive. No one wants to buy under present conditions. Some re-sale and first-hand metal is being offered daily which, with other influences, has caused a declining tendency. The market is really so heavy that it falls naturally itself. The quotation for spot and early-delivery electrolytic has declined steadily until on Tuesday it had reached 34c., New York. There is no considerable buying for either second or third quarter, despite reports to that effect in the daily press. Second-quarter metal is held at 33 to 34c. It is reported that the United States Government will buy at least 90,000,000 lb. more copper, besides the purchase made in March. It is expected that the same low price of 16.67c. per lb. will prevail. It is pointed out that because of continued success on the Western front the Allies will not make any purchase for the last half before May, anyhow. One prominent dealer is quoted as saying that he would not be surprised to hear of large sales of electrolytic at 25c. for last-half or last-quarter delivery. Exports for March are estimated at 31,250 tons, in the absence of prohibited official returns. The average price of copper for March, as quoted in *The Iron Age*, was 35.85c., New York, for both Lake and electrolytic.

LEAD

Last week, up to March 31, there was a better demand than for some days, but it was spotty, or irregular. Export requirements were good and demand from sheet-lead manufacturers was fair. Total sales for all of last week probably reached 4000 to 5000 tons, most of it for late delivery. Some spot-lead sold at 9.62½c., New York. For early delivery 9c., f.o.b. Chicago, was quoted, with 9c. for Eastern shipment in May. This week the market has been decidedly quiet and buying has halted, influenced probably by national events. The railroad situation has righted itself almost completely so that all anxiety has been eliminated as to arrivals from the West. The quotation yesterday was 9.35c., New York, or 9.15c., St. Louis, for early delivery. If producers have made any arrangement to furnish

the United States Government with lead needed for war purposes, the fact has been kept quiet. There is no change in the price of the American Smelting & Refining Co., which is 9c., New York.

TIN

Business in the past week has been almost nothing. The entire market is very dull, influenced by the same important factor that has dominated other markets. On March 28 excessive dullness prevailed, the only business done being about 20 to 25 tons of off-grade metal. On March 29 perhaps 100 tons in all was sold and the demand for spot declined to nearly nothing. Since then the market has been absolutely listless and the present condition could not be any more lifeless than in mid-summer. The effect of recent fairly large arrivals, and the slight demand, have caused a recession in the quotation for spot Straits to 54.25c., New York, yesterday. The London market has eased off to £214 2s. 6d. for spot Straits, which is about £4 lower than a week ago. Arrivals thus far in April are 275 tons with the quantity afloat reported at 2226 tons. In March total American deliveries were 4804 tons, of which 1404 tons came through Pacific ports, the unusual heavy arrivals there being accounted for by the probable selection of the safest routes. The average price for tin in March was 54.38c., New York. Tin in stock and landing on March 31 was 3362 tons.

SPELTER

There has been more activity the last two or three days as to inquiries but very little is reported sold. The market continues dull and stagnant and price changes are insignificant. The quotation for prompt and April prime Western is still 10.50c., St. Louis. For May and June 10.25c. is asked with 10c. quoted for July. The high price of ore continues its influence as a steadier of prices, some producers of spelter having a small margin of profit under present conditions. The first change in 11 weeks in the official price of British spelter was made April 2 by an advance of £8 per ton on both prompt and future deliveries. Zinc ore is reported as having fallen \$5 per ton last week to \$88.40 for high-grades and \$85 for assay-base, 60% zinc.

ANTIMONY

Despite fairly large arrivals of Chinese and Japanese grades the spot market continues nominally high at 36c. with the metal very difficult to obtain. Spot demand at present is small. In futures March shipments hold the centre of the stage at 16 to 16.50c. c.i.f. in bond, New York.

ALUMINUM

The market is uninteresting and quiet with no change. The quotation for early delivery of No. 1 virgin metal, 98 to 99% pure, is 59 to 60c. Some sellers expect the Government to buy soon.

ORES

ANTIMONY. Antimony ore is scarce. While there are considerable inquiries reported no business has been transacted.

MOLYBDENITE. There is little change in the market position. The prices previously quoted are fully maintained but business is impossible to secure as buyers now insist upon guaranty of manufacturers to supply old contracts. New business is impossible to secure, as buyers now insist upon guaranties of delivery.

TUNGSTEN. Both the domestic and foreign demand continues excellent. France and Italy are both in the market and considerable has been sold to domestic consumers at \$16.50 to \$18 per unit, depending on the quality, quantity, and delivery. Demand for ferro-tungsten is good with the quotation at about \$2 per lb. of contained tungsten.

Company Reports

AMERICAN SMELTING & REFINING CO.

The eighteenth annual report announces earnings for the year 1916, after deducting general expenses, fixed charges, and corporate taxes, of the handsome sum of \$25,242,297. The increase in net receipts amounts \$8,999,877 over those for 1915, and to \$14,430,382 over earnings made in 1914. A depreciation charge, including depletion of ore-reserves, of \$1,990,047, was deducted from the net earnings, in addition to \$575,000 distributed as employees' bonuses, \$275,000 appropriated for pension-fund, and \$150,000 for welfare-work. After meeting obligations on account of preferred stock, there was left applicable for dividends \$16,158,991, being in excess of 30% on the outstanding shares, in addition to the regular quarterly dividends at the rate of 6% per annum. A sum of \$6,000,000 was carried forward in the reserve fund for enlargement and extension. The prevalent high prices have stimulated production of ore and bullion, and the smelting and refining operations of the company have correspondingly increased. At the same time the cost of fuel, miscellaneous supplies, and the wages paid to labor, have advanced to such a degree as to make the management of the complex operations of the company most difficult. Some departments of this group of related industries have been unprofitable, but there have been compensating gains in other departments. The policy of the company is declared to be one of expansion, so that a large proportion of the abnormally high net earnings will be devoted to preparations for more diversified production in the future, so as to insure a continuance of earnings which could not otherwise be expected. None of the Mexican smelting plants of the company were operated during the year 1916, but a few of the mines were worked, entirely under Mexican supervision. In efforts recently made to resume normal operation at the Monterrey and Matehuala plants it has been found necessary to move all materials with the aid of locomotives and cars belonging to the company. The Board of Directors, however, expresses the opinion that "all business in Mexico must expect to be greatly hampered by high costs, especially in taxation and freight." In Chile a policy of general expansion has been decided upon, and the company has purchased the Caldera smelters, "together with a highly mineralized zone, including many mines, which are but imperfectly developed. There has been purchased also the stock of the Carrizal Smelting Co. An important and favorably developed mining property in Mexico adjoining the mines of the company at Parral was secured at a value which was believed warranted, even if operations may be considerably delayed."

More than \$5,000,000 was expended in betterment of the copper-smelting and refining plants, owing to the increasing demand for electrolytic copper. By the middle of this year the company will have a capacity for producing 1,300,000,000 lb. of electrolytic copper per annum. The large decrease in supplies of lead ore formerly derived from the Coeur d'Alene mines has led to the expenditure of about \$750,000 in the development of the company's properties in Missouri. A sulphuric acid plant, with a capacity of 50,000 tons per annum, has been completed at Salt Lake, and this will be duplicated as soon as a market for the acid can be found. An appropriation has been made for a research laboratory having in view the development of chemical industries in which larger quantities of sulphuric acid may be utilized. Closer attention is also being given to the saving of the minor metals and valuable non-metallic substances present in the ores treated at the company's works. The magnitude of a great smelting industry is illustrated by the cash receipts during the year of \$358,117,836, and from the striking comment in the report regarding metal-stocks, as follows: "At no point in the accounts sub-

mitted is the enormous increase in business being done at the ending of the year, as compared with the beginning of the year, so vividly portrayed as in the inventory-value of metal-stocks. The book-value of ore, bullion, and factory-products on hand and in transit on December 31, 1916, less treatment-charges accrued but not earned, was \$105,254,064.81 as compared with the value of the same stock at the end of the preceding year, \$58,582,142.69, or an increase of \$46,671,922.12. This increase is very largely in the weight of metal carried in the normal business of the company, as the average inventory-price at which metals are carried has not been increased during the year. Of this enormous increase, however, \$42,813,133.96 is for account of mining companies. The increase in inventory value of metals held at the risk of the company during the year is \$3,858,788.16, which is only the normal increase made necessary by the total increase of material delivered to the smelting and refining works, together with the added carry, on account of delays in transit from smelters to refineries, due to the congestion of traffic, with which the whole country is acquainted.

ISLE ROYALE COPPER CO.

The directors of the Isle Royale Copper Co. submit the following report of the operations of this company for the year ended December 31, 1916:

Gross value of fine copper produced:

12,412,111 lb.	\$3,209,537.18	
Silver sales	53,086.76	
		\$3,262,623.94

750,000.00

PHELPS, DODGE & CO.

Earnings of Phelps, Dodge & Co. for the year 1916 amounted to \$24,030,905, an increase of 140% over the previous year. On the stock there was earned last year 53.4%, against 24.4% in 1915 and 14.8% in 1914.

The income account compares as follows:

	1916	1915	1914	1913
Net earnings ..	\$24,030,905	\$10,981,512	\$6,664,839	\$9,407,710
Dividends	14,625,000	9,000,000	6,300,000	7,425,000
Ore depl. and plant dep. ...	2,056,642	1,261,037	*1,500,000
Surplus	7,349,263	720,475	364,839	482,710
Previous surplus	8,337,864	7,617,389	6,646,270	6,163,560
Total surplus.	15,687,127	8,337,864	7,011,109	6,646,270

*Depreciation in value of stocks owned.

At the end of 1916 Phelps, Dodge & Co. had current assets of \$24,482,131 of which \$7,746,520 was cash, \$3,062,032 market-

able securities, \$4,031,300 accounts receivable and \$7,993,924 representing metals in process of treatment and on hand. The balance of \$1,648,355 was merchandise held for sale. Current liabilities totaled \$5,826,777 of which the largest item was \$3,830,597 representing accounts payable. President James Douglas says: "Production of copper for the past year has greatly exceeded any in the company's history. The metal produced from the ores of the constituent companies of Phelps, Dodge & Co., Inc., was 152,263,729 pounds of copper, 10,404,341 pounds of lead, 1,642,055 ounces of silver and 28,873 ounces of gold; and in addition there was purchased or smelted on toll at the reduction works of the company ores yielding 37,823,828 pounds of copper, 588,327 ounces of silver, and 7802 ounces of gold. Including copper received from other sources, 247,303,587 pounds were sold and delivered to buyers at an average price of 24.48 cents per pound net cash f.o.b., New York:

	Pounds
To domestic trade	176,468,527
To foreign trade	70,835,060
Total deliveries	247,303,587

Phelps, Dodge & Co. sold	
Of their own mine product	138,968,320
Of copper from ores purchased	34,742,080
Of copper on commission	73,593,187

"The stimulation of high prices, together with the satisfactory settlement of the labor difficulties in Morenci, improved political conditions in Sonora, and the inception of production at the Burro Mountain property, served to increase over 1915 output of copper 25,492,039 lb. and a total of 48,957,135 lb. from the reduction plants, which includes ores purchased or smelted on tolls."

CALUMET & ARIZONA

The Calumet & Arizona Mining Co. reports for 1916 net earnings of \$17.36 per share, from which dividends of \$9 were paid. The income account and production figures compare as follows:

	Received for copper, gold, and silver	Operating expenses	Net income
1916	\$20,495,430	\$11,156,835	\$11,155,005
1915	11,647,415	6,225,595	5,453,881
1914	8,518,999	5,303,375	3,085,535
1913	9,181,995	4,960,528	4,074,637
1912	9,131,967	4,547,973	4,550,883

Operating statistics:

	Copper, lb.	Cost copper per lb., c.	Silver, oz.	Gold, oz.
1916	74,898,788	9.04	1,863,149	43,378
1915	65,268,910	*	1,381,078	35,264
1914	52,667,929	8.19	922,143	24,122
1913	56,987,383	7.65	880,915	19,989
1912	53,108,628	7.02	594,319	22,881

*Not reported.

Underground development work during the year aggregated 125,282 ft. as compared with 93,789 ft. in 1915.

Under the sliding scale of wages the miners received a maximum of \$5.85 per day in December as against \$3.60 per day in 1914.

BRUNSWICK CONSOLIDATED MINING CO.

The annual report of the Brunswick Consolidated Gold Mining Co. of Grass Valley, California, shows a total production of the mine from 1893 to December 31, 1916, of \$1,582,846.90. Nine dividends have been declared, aggregating 51 cents per share. There have been levied also 42 assessments, amounting to a total of \$1.22 per share. During the year 1916 a total of 34,091 tons of ore was crushed, producing \$196,520.99; of which \$166,573.51 was in bullion and \$29,947.48 was from concentrate. The average assay-value of the ore was

\$6.435 and that of the tailing \$0.671. The average extraction of value was 89.5%. Costs were distributed as follows:

General expense	\$0.5896
Mining	3.8745
Milling	0.8304
New shaft	0.2491
Repairs	0.1530
Improvements	0.2011
Total	\$5.8977

OSCEOLA CONSOLIDATED MINING CO.

The Osceola Con. Mining Co. of Michigan reports for the year ended December 31, 1916, as follows:

Gross value of fine copper produced	\$5,040,012.69
Interest	25,121.32

\$5,065,134.01

Running expenses at the mine	\$1,744,884.22
New construction	66,057.90
Smelting, freight, commissions, etc.	478,032.34
	2,288,974.46
Net profit	2,776,159.55
Dividends (4) during the year	1,826,850.00

Increase in current assets	\$ 949,309.55
Balance of assets December 31, 1915	2,166,646.51

Less not included in current assets:

Wood and timber lands	\$ 37,309.18
Mineral Range railroad stock	341,100.00
Lake Superior Smelting Co. stock	60,000.00
	438,409.18
Balance of current assets December 31, 1915	1,728,237.33

Balance of current assets December 31, 1916	\$2,677,546.88
---	----------------

SILVER KING CONSOLIDATED MINING CO

The Silver King Consolidated Mining Co. of Utah reports for the year ended January 31, 1917, as follows:

RECEIPTS

Balance February 1, 1916	\$232,644.72
Ore sales	500,498.52
Miscellaneous income	175,746.71
Total	\$908,949.95

DISBURSEMENTS

General expense	36,107.00
Mining	110,432.25
Other expenses	47,571.06
Surface improvements	102,035.64
Dividends	294,561.56
Miscellaneous	318,242.44

Total

YUKON GOLD

The Yukon Gold Co. reports for the year ended December 31 last as follows:

Received from gold operations	\$4,383,595
Operating expenses	2,291,235

Operating income	\$2,092,359
Other income	9,342

Total income	\$2,101,701
Charges	994,191

Balance

Recent Patents

1,209,835. PROCESS OF TREATING MATERIALS ELECTROLYTICALLY. William E. Greenwalt, Denver, Colo. Filed May 13, 1913. Serial No. 767,392.

1. An electrolytic process which consists in maintaining separate the anolyte and catholyte with a suitable diaphragm, simultaneously agitating both the anolyte and catholyte and withdrawing the electrolyte from one compartment and passing it through the other compartment without mingling with the electrolyte of the other compartment.

1,209,934. CONCENTRATING-TABLE. Emil Deister, Fort Wayne, Ind., assignor to Deister Machine Company, Fort Wayne, Ind., a Corporation of Indiana. Filed June 15, 1916. Serial No. 103,809.

1. A transversely inclined concentrating-table having a deck, means for vibrating the deck, riffles arranged on the deck substantially parallel with the direction of vibration, means for feeding the material onto the head of the table, said table being downwardly inclined from the head to the tailings discharge edge, but substantially level in the direction of vibration, the riffles having their upper surfaces in a plane substantially parallel with the main surface of the deck for substantially their entire length, in combination with a plateau, substantially parallel with the main surface of the table and arranged along the mineral discharge edge, and an inclined surface arranged diagonally across the deck for causing the valves to move up above the surface of the material overlying the main surface of the deck and onto the plateau.

1,211,828. APPARATUS FOR THICKENING AND AGITATING PULP. John Van Nostrand Dorr, Denver, Colo. Original application filed Sept. 9, 1912. Serial No. 719,465. Divided and this application filed June 26, 1913. Serial No. 775,884.

Apparatus for thickening and agitating pulp, comprising a series of vessels each provided with a separator having on one side a chamber in which the pulp is agitated and on the other a space for quiet settling, means in said chamber for thoroughly agitating the thickened pulp, means connecting the agitating chamber of one vessel with the settling space of another, and means for conducting the clear liquid from

one vessel to and mixing it with the thickened agitated pulp passing from the agitating chamber of another vessel in the series before said agitated pulp descends to another settling area.

1,207,127. METHOD OF AND APPARATUS FOR OBTAINING ZINC. Edward S. Berglund, Trollhättan, Sweden, assignor to Trollhättans Elektrotermiska Aktiebolag, Trollhättan, Sweden. Filed Sept. 15, 1914. Serial No. 861,758.

1. In extracting zinc in an electric furnace the method of reducing and purifying the metallic vapors developed in the furnace, consisting in passing said vapors after leaving the furnace and on their way to the condenser, over a layer of reducing material, without passing them through such material and heating them above the condensing temperature.

1,210,017. ELECTROLYTIC RECOVERY OF ZINC FROM ORES AND OTHER ZINC-BEARING MATERIALS. Urlyn Clifton Tainton, Johannesburg, Transvaal, South Africa. Filed Aug. 10, 1915. Serial No. 44,837.

1. A continuous electrolytic process for the extraction of zinc from zinc-bearing material which consists in forming therefrom a concentrated solution of a zinc-salt containing an excess of acid, electrolyzing the solution with a current of high density, regenerating the said solution by dividing it into two portions in such proportions that, when the acid in one portion is neutralized by the addition to it of a charge of zinc-bearing material and the resulting solution separated from the residue and mixed with the other portion of the electrolyzed solution which has been retained, the acid-content of the final solution shall be approximately the same as that of the original solution and then electrolyzing the regenerated solution with a current of high density.

1,205,944. PROCESS FOR SINTERING FINE ORES, FLUE-DUST, PURPLE ORE AND THE LIKE. Carl Giesecke, Bad Harzburg, Germany. Filed Aug. 30, 1916. Serial No. 117,735.

1. The herein-described process of sintering finely-divided material containing iron, which consists in mixing such material with slimes; agglomerating the mixture; and heating the agglomerate, together with finely-divided fuel, in a shaft furnace.

2. The herein-described process of sintering finely-divided material containing iron, which consists in mixing such material with slimes containing a high percentage of clay; agglomerating the mixture; and heating the agglomerate, together with finely-divided fuel, in a shaft furnace.

1,207,243. PROCESS FOR THE RECOVERY OF METALS FROM ORES AND THE LIKE. Charles S. Vadner, Butte, Mont. Filed May 23, 1916. Serial No. 99,465.

1. In the art of recovering copper and other metals from mineral matter and the like consisting in treating the naturally oxidized or sufficiently roasted sulfid ore with sulfurous gases and the like in the presence of heat and a solution containing at least one of the common chlorides that can react, for the purpose of effecting the desired reactions, leaching out the metals from the mineral matter eliminating excess acidity of solution, passing air through same thereby precipitating iron as ferric oxide, eliminating same, further eliminating excess acidity of solution and sufficiently heating same whereby copper is precipitated as cuprous chloride.

Mining Decisions

OIL LEASE—NATURE OF LESSEE'S TITLE

An ordinary oil lease vests no title in the lessee to the real estate, but only the right to explore for and extract the oil.

Kelly v. Harris (Oklahoma), 162 Pacific, 219. January 23, 1917.

MINING ROYALTIES—CLASSIFIED AS LAND RENTS

Royalties from a mine were held to be "rents and profits from lands" in construing a trust.

In re Petit's Estate (Minnesota) 161 Northwestern, 158. January 26, 1917.

STATE LANDS—LEASE OF MINERAL RIGHTS

Under a statute providing for leases of unencumbered mineral lands, the State cannot make a lease of mineral rights on oil lands which have been previously sold under contract with a reservation to the State minerals, unless provision is first made to compensate the surface purchaser for damages from drilling operations.

State v. Savidge (Washington), 161 Pacific, 471. December 12, 1916.

MINING CONTRACT—SUIT FOR ROYALTIES

The parties defendant entered into an agreement to buy a mine for a certain price in cash, balance to be paid in royalties. The cash price was paid and the deed delivered but the defendants never commenced mining, nor was there any specific provision in the agreement that they must commence work within a given time or at all. Held, on a suit for recovery of the balance of the purchase price that the defendants were not required to pay it unless they elected to commence mining operations.

Johnson v. Geddes (Utah), 161 Pacific, 910. December 28, 1916.

PATENT PROCEEDINGS—THEORETICAL EXCLUSIONS

Where exclusions are made from the application for patent of mining claims of supposed conflicts with a prior patented claim, and the position of the prior patented claim as actually marked, defined and established upon the ground is not identical with its position as represented upon the plat and described in the field notes of survey, and the supposed conflicts have no existence in fact, the areas represented by such theoretical exclusions pass under the patents to the claims and are therefore not subject to appropriation by subsequent location.

Wasatch Mines Company (Land Department), 45 Land Decisions, 10. March 15, 1916.

RAILROAD PATENT—MINERAL CHARACTER—BURDEN OF PROOF

The return of the Surveyor-General as to the character of land in an application for patent of a railroad listing constitutes a small element of construction where the question as to the character of the land is at issue. Where the question of mineral or non-mineral character is put in issue by the report of a special agent, the burden is upon the railroad company to show by clear and convincing evidence that the land is non-mineral. It is not incumbent upon the government to show a discovery of mineral such as would serve as a basis for mineral patent. It is sufficient to justify denial of the railroad patent if the land be shown to have a prima facie mineral character and a prospective value for minerals greater than any other known value.

Central Pacific Railway (Land Department), 45 Land Decisions, 25. April 7, 1916.

Recent Publications

THE MINERAL RESOURCES OF OREGON. Vol. 2, No. 4. A handbook of the mining industry of the State, with a description of mining districts. By H. M. Parks, State Geologist, and A. M. Swartley. Pp. 306. Maps, Ill. Oregon Bureau of Mines, Corvallis, 1916. This work, the latest of the monthly publications of the Oregon State Bureau of Mines, is a valuable and timely compilation of the mines, quarries, and mineral-producing industries of that State, alphabetically arranged. Many of the more important mines are carefully described, and the descriptive text of some of them is illustrated by line drawings, maps, and half-tones. The geology of the principal mining districts is also gone into, and on the whole the book will be found an acceptable addition to scientific mining and geological literature of Oregon.

REPORT OF THE ROYAL ONTARIO NICKEL COMMISSION. Pp. 528. Ill. and maps. Toronto, 1917.

This valuable volume contains the findings of the Commission appointed by the legislative assembly of Ontario, to investigate thoroughly the nickel industry of Canada, including mining and reduction of the ores and refining of the metal. The Commission visited the nickel mines of the world, and investigated the nickel industry from every point of view, and their findings are of value to all interested, not only in the production of nickel, but in every industry wherein nickel is used in any form. The two questions given the greatest weight during the investigation were, can nickel be economically refined in Canada? and are the nickel deposits of Ontario of such a character that the Province can complete successfully as a nickel producer with any other country?

WEST VIRGINIA GEOLOGICAL SURVEY, Morgantown, W. Va., comprising the detailed geology of Jefferson, Berkeley, and Morgan counties. By G. P. Grimsley, pp. 644 + XXVI. Ill., with maps. Price, with case of maps (delivered), \$2.50. Extra copies of map, \$1.

THE PRODUCTION OF CEMENT, LIME, CLAY-PRODUCTS, STONE AND OTHER STRUCTURAL MATERIALS IN CANADA IN 1915. Department of Mines, Ottawa, 1916.

THE PRODUCTION OF COPPER, GOLD, LEAD, NICKEL, SILVER, ZINC, AND OTHER MINERALS IN CANADA IN 1915. Department of Mines of Canada, Ottawa, 1916.

Commercial Paragraphs

The LUNKENHEIMER Co., of Cincinnati, Ohio, states that during the past year, there was a great demand for valves made entirely of iron for use in handling cyanide and other solutions which attack metals having copper as their basic element, and which consequently could not be handled by brass-valves or valves having any part made of brass. This company supplied a large number for use in dye and chemical manufacturing plants, but the demand was not confined to these sources, as quite a number were also supplied for use in mines, oil-refineries, tanneries, pulp and chemical fiber-mills, canning and packing-establishments.

Bricks recovered from the walls of old buildings have for years been cleaned by men who laboriously chipped off the tightly adhering mortar. This method has been superseded by the air-hammer, which quickly removes the mortar and renders the brick as good as new. Old paving-bricks also can be renovated in the same manner. The work is generally accomplished by means of a small portable compressor, such as the Sullivan 15-hp. class WK-3, a portable single-stage machine, operated by a gas-engine, as described in *Mine and Quarry* for March. The hammer used is the Sullivan DA-15, 25-lb. plug-drill, and a Sullivan DB-13 hand-pushing machine, equipped with bits like those on a cold-chisel.

EDITORIAL

T. A. RICKARD, Editor

SPEAKING of patriotism, we confess to admiration of *The Spectator*, that lineal descendant of the paper founded by Addison and Steele, for its present proprietor, being called upon by the new regulations of the British government to decrease the number of pages in his periodical and so save freightage on paper-pulp, cut out his advertising pages.

THE PRESIDENT has called upon every citizen to co-operate in the national effort to wage an effective war "for democracy and human rights." He appeals, among other elements in the population, to the miner in these words: "To the miner let me say that he stands where the farmer does. The work of the world waits on him. If he slackens or fails, armies and statesmen are helpless. He also is enlisted in the great service army." What he says about extravagance, personal and industrial, should be noted in every mine, mill, and smelter: "This is the time for America to correct her unpardonable fault of wastefulness and extravagance. Let every man and every woman assume the duty of careful provident use and expenditure as a public duty, as a dictate of patriotism which no one can now expect ever to be excused or forgiven for ignoring."

ON another page we give information concerning the enlistment of men for the Engineer Reserve Corps of the Army, so that those willing to serve may know to whom to apply and under which branch of this particular service to enroll themselves. As soon as they are needed they will be called into active service. Undoubtedly a large proportion of the personnel engaged in mining, from trapper to manager, can find suitable and congenial employment in the Engineer Corps and we recommend it to them as being preferable to enlistment in the line. Without unduly depreciating the patriotic sentiment expressed by the organization of home guards, troops for State defence, and the like, we venture to lay stress on the need for meeting this crisis in a truly national spirit rather than as citizens of any political or municipal sub-division of our country. This War can be brought to a successful issue only by a loyal and co-ordinated effort on the part of all its citizens without distinction of town or State.

MISUNDERSTANDING exists as to the ownership of the Cottrell patents. Mr. F. G. Cottrell assigned the right to administer his patents for all smoke-work throughout the United States, except in Arizona, California, Oregon, and Washington, to the Research Corporation, acting in behalf of the Smithsonian Institution. The right of application to industrial smokers in the four

States excepted is held by the Western Precipitation Company, which also retains the right to apply these patents to the cement industry throughout this country. This company likewise controls the foreign patents to the Cottrell inventions, and recently sold its rights in Japan for a handsome sum to a syndicate composed of four well-known Japanese smelting companies. To this we may add the news that the Anaconda Copper Mining Company has decided to proceed with the erection of a big Cottrell equipment, the first being designed to treat 3,000,000 cubic feet of gas, this plant to consist of 20 units, each capable of treating 150,000 cubic feet per minute at a velocity of six feet per second. In the newer plants the detaching of the sublimate from the tubes is effected by a lever, so as to obviate the crude method of employing a man to hammer the tubes in order to collect this product. Noise and smoke usually indicate rudimentary or incomplete metallurgical processes.

CRITERIA for distinguishing, by a study of the ore-minerals in a deposit, the conditions under which deposition occurred are of the highest practical value to engineers entrusted with the responsibility for developing mines. Astute recognition of the criteria means correct inferences as to probable structural habit of the orebody and its relationship to the associated rocks. Rightly or wrongly, all men, from the prospector to the trained economic geologist, judge the ores they meet in their work and draw conclusions from what they see as to the place and character of the ore unseen. Such a contribution to the interpretation of genetic evidence as that contained in the paper by Messrs. C. F. Tolman, Jr. and Austin F. Rogers, published on another page of this issue, will be eagerly received. It throws new light upon magmatic segregations of sulphide minerals, and adduces proof that such concentrations represent a closing phase of the consolidation of the magma, and even follow the solidification of the quartz, but that they are not to be confounded with hydro-thermal deposits, which may be formed either at a still later stage, or entirely beyond the limits of the rock from which the mineralizing agents proceeded. Opportunity to observe the peculiarities presented by ores of the character under discussion coming from exceptionally deep Californian mines adds further significance to the discriminations that these investigations offer as a guide to geologists.

AMONG the curiosities of promoting 'literature,' we may mention the prospectus of the Arizona-Tonopah Mining & Co. company as published in a pamphlet entitled 'Facts.' Among sundry glittering statements concerning the dividends paid by famous mines the reader is

assaulted by an electric sign telling him to "Watch Arizona-Tonopah go to a dollar per share" and similar electrifying assertions. We are told that whereas railroads return 3% on the capital invested in them and National Banks 6½, it is a 'fact' that mining pays 182% on the capital invested. This cheerful lie is said to be based on "some Government data." *Some data!* Among other romantic yarns, we are told that a "railroad engineer now living in Pueblo, Colorado, let a friend talk him out of buying \$300 worth of Mollie Gibson at 1½ cents per share. This same man saw Molly Gibson stock advance to \$15 per share in less than a year, and today grieves over the fact that he let a friend talk him out of \$372,000 which his own conscience told him to buy." No wonder his conscience was grieved—also his pineal gland. But how about the thousands of men that bought other stock at \$1.50 on the same kind of tip and saw it go to 1½ cents per share? Ask George Graham Rice and the gentlemen that play the 'game' of peddling wild-cat stocks. Instead of reports by well-known engineers the possible speculator is given the story of the cabalistic signs deciphered by "the most eminent entomologists." The signs on the rocks were examined by these 'entomologists'—a good word, having something to do with bugs, in the head or elsewhere—and they pronounced the meaning of the inscriptions to be 'Great Mines' or 'Rich Mines.' That, of course, settles it—what could be better than this laconic report written 000 years ago. The cabalistic signs pointed in the direction of "the veins or leads of ore." Thereupon, of course, the original discoverer, who is also the general manager and treasurer—especially treasurer—of the company proceeded to uncover the Aztec treasure-house in which, dear reader, you and we are given the opportunity to acquire such wealth as will give us greater ease and dignity without unnecessary fuss.

EVEN clever people make simple mistakes. We have been surprised repeatedly to find how many of the Japanese gentlemen that come to this country on a mining and metallurgical tour are unable to speak English with any comfort or success. It would appear to us, judging from our own experience, that a round of visits of observation to mines, mills, or smelters might be ineffective as a means of collecting accurate information so long as the visitor is unable either to ask precise questions or to understand specific replies in the language of the country. The chances for misunderstanding must be enormous and we can quite imagine that some of the younger Japanese engineers return home with a weird assortment of undigested data. We mention the matter in the interest of all concerned, not only the visitors but the managers of mines and smelters to whom the lack of an effective medium of speech is an insuperable block to the giving of mental hospitality. We are fully aware that this criticism in its rebound strikes a national weakness of our own. Probably not one American out of ten thousand that has visited Japan went equipped with a dozen words of Nipponese. Our

conceptions of the Mikado's empire, its ideals, and its purposes are consequently a mixture of conjecture, sentiment, and official misinformation. We have but little more to our credit as regards comprehension of the institutions and the peoples of Latin America. Our merchants have sent hordes of commercial travelers into South America and they have developed no important trade; our periodicals have repeatedly commissioned correspondents to reveal to us our southern neighbors, and they have either maligned them or treated them as a joke, at the same time filling columns with meaningless statistics of trade opportunity abstracted from the files in the Bureau of the American Republics at Washington. Although there exists a large body of American mining engineers who possess a moderate command of the Spanish language, the majority of mining enterprises in the countries to the south have suffered through the inability of those in charge to use the current medium of communication. A great part of the general imputation of inefficiency on the part of Latin-American labor, and of corruption on the part of the officials, has its origin in failure to understand; the man who is not alert to the thought of those around him offers temptation to profit at his expense.

CARRANZA has donned a garment of neutrality, but it was clearly not cut to measure. It is a cheap 'hand-me-down,' which fails to cover the naked truth of his international policy. Little more than a month ago he was posing as a pacifist, declaiming against the barbarisms of war and proposing by a circular letter to all the republics of America that they refrain from the exportation of munitions and supplies to Europe. This is the kind of neutrality that is meant to neutralize the efforts of one belligerent for the advantage of the other. The inspiration for this species of fraternal affection is not difficult to trace. Meanwhile evidence has accumulated showing that he has allowed Mexican ports to be used as a base for German submarines, and that more recently he has connived at the use of a Mexican railroad with shops and terminal facilities in promoting a submarine campaign in the Pacific aimed primarily against the shipping of this country. This is in striking contrast with his obstinate refusal to permit the American troops to use the railroads in Chihuahua when sent in pursuit of Villa, who was then assumed to be the common enemy of the United States and of the so-called *de facto* government. At the same time it is noteworthy that by nationalizing the oil-fields, subjecting them to bureaucratic control under the provisions of the mining law, he is preparing to take advantage of any technical opening that could be found for harassing American and British interests. The old adage, "He that is not with us is against us," would seem to apply with peculiar force to our 'neutral' neighbor. No one can mistake the hostile purpose conveyed in the cryptic response of Carranza to the diplomatic representatives of this government, expressing regret that the United States should have been unable to solve its difficulties

with Germany in a peaceful manner, and assuring us that Mexico would omit no effort to contribute to the bringing about of peace. It assists to an understanding of this mellifluous phrase to recall the sanguinary significance of 'pacification' as used in Hispanic military decrees. Concurrently with other disquieting news come reports of more than five thousand Mexicans quitting work in southern California within the last two weeks and withdrawn to their own country, from which most of them had fled as political refugees or to avoid military service with the revolutionary factions. Coupled with persistent reports of the pernicious activity of German agents in Mexico City, the address by Carranza at the opening of congress, wherein he sets forth his grievances at labored length, intensifies the prevalent distrust of his motives. He accuses the United States of official misrepresentations, and sullenly characterizes the late punitive expedition as war upon Mexico. These are not words of peace coming from the man who owes his present position to the active support of this Government. A cordial understanding between the United States and Mexico at this time would instantly lead to the rehabilitation of Mexican industry and finance and would strengthen the hands of the existing government. It must be assumed that the acts of Carranza are dictated by his vision of selfish interest.

Business Not As Usual

Several of our Eastern contemporaries, not fully realizing the extent of the industrial re-organization that military preparation must involve, have made what we venture to call the serious mistake, on the morning of the declaration of war against Germany, of going out of their way to recommend 'Business as Usual,' in the course of which they re-iterate the slogan adopted by the British at the beginning of hostilities. The advice to keep cool, not to slacken routine effort, to throw fresh energy into constructive work, to expand business with a view to "giving strength to the man who actually fights," and so forth, is well enough in its way, but it is only too likely to be converted into selfish detachment and crass self-interest. The Great War has given us three infamous or pitiable sayings—each reader may select his own adjective, gently or strongly opprobrious, as he sees fit—those three are "a scrap of paper," "business as usual," and "too proud to fight." Two of them have gone to the scrap-heap; the first has yet to be driven down the throat of him who uttered it. "Business as usual" is not for us to echo. When the guns of Liège could almost be heard in England, the business was considered so usual that young men played cricket and older men played golf as if nothing had happened. They have learned since then how their unpreparedness has cost the lives of thousands of brave men and prolonged the War by months and years. They have atoned honorably and gloriously for their early mistake; we shall have no excuse for committing a like blunder, for their example is too recent. Let us imitate not the blunder

but the splendid rectification of it. The business in which we are engaged is most unusual and we should realize it every moment of our day. All that we do should have a newer meaning and a deeper purpose—to serve our country, to work for a great cause, to do our share in promoting the only result that will make the world a fit place where free men may live and pursue happiness in an orderly way.

Mining Law Revision

Revision of the mining law will be taken up at the long session of Congress in December. This news comes from Washington upon the authority of Dr. Martin D. Foster, chairman of the committee on mines and mining. Dr. Foster has expressed distaste for the inactivity that has been forced upon his committee in the past. He complains that demands for revision were made, and that as soon as the committee showed signs of taking seriously such requests from men interested in mines, insistent demands for delay came from other equally important groups. He also made the remark, not without a smile, that while no constructive aid broadly representative of American mining was offered the congressional committee in framing a bill, lively interest in the movement for new legislation was taken as soon as a proposal was submitted for a junketing expedition to visit the leading mining centres of the West at Uncle Sam's expense, ostensibly for the collecting of evidence as to the specific needs of mine-owners and operators, and the difficulties to be overcome by a new statute. We have criticized the Foster bill, which was drawn up solely to stimulate discussion. The committee and its chairman desire to make progress toward revision, and they have earnestly invited those whose business gives them an understanding of the needs of the miners to submit one or more bills for consideration, based upon which a workable mining law may be framed. They appear, however, to underestimate the value of the suggestions, going so far as the drafting of new regulations, proposed by the committee of the Mining and Metallurgical Society and they overlook the work done by numerous committees, one of the more important being that selected by the American Institute. Apparently there is a lamentable failure to co-operate between the mining societies and the gentlemen in Congress. They do not appear to have such sympathy and respect for each other's efforts as is necessary to effective legislation. Dr. Foster himself acknowledges that he knows nothing about mining; he is a physician by profession; he claims, however, to have an open mind and to be willing to listen to good advice. As we have suggested more than once, any radical change in the mining law will be dangerous unless it comes as the logical consequence of a thorough revision of the entire system of land laws, after these have been studied carefully by a commission specially qualified to pass judgment. We are glad to state that Senator Smoot has seen the error of his ways and abandoned his scheme of piece-meal revision; he has now in-

troduced a bill providing for a commission of three experts, giving them a year to study the mining laws of various countries before formulating suggestions for a new code. The present law is faulty in many ways, but the intent of it has been clarified by a long series of court decisions so that the miner knows fairly well just where he stands in relation to the Government and his fellow citizens. To repeal the 'law of the apex' without a thorough revision of the other regulations will land the mining community in a new maze of lawsuits and leave us worse confounded than before. Dr. Foster and his committee had better not 'monkey with a buzz-saw' until they know more about the mechanics of the thing. The duty of those who are interested in the industry is manifest. The campaign for new legislation will end in a joke or a disaster unless the men who have the matter at heart lay aside questions of pique and precedence, and work in harmony.

Deeper Mining at Treadwell

Our readers will be interested to learn that plans for the deeper development of the Treadwell group of mines are being put into effect. This is in accordance with the recommendations of the president of the three consolidated companies, Mr. F. W. Bradley, as embodied in his report of October 20, 1916. A constructive programme was summarized in that report, including the equipment of the Combination shaft, first with a man-hoist and then with an ore-hoist. In 1916 the Alaska Treadwell earned \$432,670 and the Mexican \$5760, while the United made a loss of \$129,530, this last being due to the unusual proportion of underground work in the 700 claim and the new shaft on the Ready Bullion. The diamond-drilling of the deeper ground was completed recently, the first 345 feet of the last bore, which started from the 2300-ft. level, cutting through ore averaging \$2.42. The diamond-drilling campaign has developed 3,887,000 tons of \$2.25 ore between the 2300 and the 2700-ft. levels. A similar stretch of ground in the upper levels would have shown 5,600,000 tons of \$2.63 ore. However, the progressive improvement in the deeper workings since the poor zone was entered at 1750 feet is shown by the sampling and drilling, the averages being:

1750-ft. level	\$1.46
1950 "	"	0.65
2100 "	"	1.65
2300 "	"	2.06
2500 "	"	2.21
2700 "	"	2.44

The economic limit is an assay-value of \$2 per ton, from which 90% is extractable. What may be the cause for the higher gold-content on the deepest levels is not known. The wall-rocks are the same. The orebodies consist of the gold-bearing portions of an albite-diorite dike. A flattening of the dip below 1600 feet and a straightening of it at about 2100 feet is associated with changes in the grade of the ore. The shortening of the ore-bearing ground in depth is due to the position of

the Star dike, which is pushing into the ore-bearing dike. The mine has had its vicissitudes. The ore exposed at the surface was profitable down to 450 feet, while another and northern orebody was poor at the surface, becoming workable at a depth of 350 feet. This northern orebody was stoped down to 750 feet, where it became poor, continuing so for 325 feet (to 1075 feet) and then became rich enough to stope from this point down to just below the 1400-ft. level. From there it has been unproductive in the Treadwell mine. Meanwhile the south, or main, orebody was poor from 450 feet to just above the 600-ft. level; from there to a point mid-way between the 1600 and 1750-ft. levels this orebody was highly productive. Below this point neither orebody was any good until about 2100 feet from the surface was reached. The poor zones in the higher levels, notably at 750 feet, were not emphasized by any diminution of output because new ore-ground was opened up so rapidly, and sufficiently in advance of mill requirements, that there was no trouble in maintaining the regular production. It requires from five to seven years to open and draw the ore between two levels. In passing we may note that much of the so-called quartz associated with the gold in the Treadwell dike is a feldspar, albite. Some streaks and patches of pay-ore have been found above the 2100-ft. level, but it is intended to leave the 200 to 250 feet of ground below the 1750-ft. level as a sheet-pillar to protect the mine from caving or inundation. The next level, at 3000 feet, will be driven from the Combination shaft, for which a powerful man-hoisting engine has just been ordered. This is a Nordberg double-drum hoist to be operated electrically by a Westinghouse 450-hp. induction-motor through a single reduction of herringbone gears. Later, an ore-hoisting engine will be erected at this shaft; it will have a capacity of 4000 tons per day from as deep as the 4200-ft. level and will be operated by a 2000-hp. induction-motor capable of being overloaded to 4400 hp. The skips will hold 8 tons of rock and will be larger than any hitherto used, so as to decrease the proportion of ore that has to be broken underground. The Central shaft has been deepened to 2700 feet and levels are now being extended. The Combination shaft, which is 1700 feet away and well outside the stoping-area, is down to 2100 feet and will be deepened forthwith, so as to facilitate the completion of the necessary connections underground. The lowest stopes are at 1600 feet, leaving 1100 feet virgin, of which about 500 feet is believed to be workable at a profit. The main orebody has shortened from 2000 feet to 1400 feet, but the area of ore, which averages 84 feet in width, is still such as to give ample scope for large exploitation. It is evident that the management is hopeful in a sanely scientific way, and the improvement in the grade of the ore in the bottom of the mine justifies reasonable optimism. It is not often that a mine 'comes again,' but signs are multiplying that the Treadwell is one of this rare kind. We join with the mining community on this Coast in best wishes for a rehabilitation of this splendid enterprise.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Difficult Mine-Sampling

The Editor:

Sir—The sampling of cinnabar ores might be mentioned in connection with the letter contributed to your issue of March 17 by W. H. Storms.

As channel-samples cut from cinnabar ore are most unreliable the sampling of the Black Butte quicksilver mine in Lane county, Oregon, was accomplished by a method which subsequent furnace-recovery is confirming.

The formation is altered andesite in which particles of cinnabar are disseminated. The best ore lies on a wall which apexes along the ridge of Black Butte and dips with the northern slope of the mountain. The assay-values shade from the wall out toward the surface. In sampling the mine an arbitrary width of 10 ft. was assumed and a 3-ft. cut of that width was taken from the backs of all the drifts. After being crushed to $1\frac{1}{4}$ inch the ore was transported to the Scott furnace by aerial tramway. On its way to the furnace every twentieth bucket was dumped into a small Gates crusher, which reduced the ore to half-inch and delivered it on the sampling-floor. The tramway-buckets carried about 100 lb. and a day's run resulted in a sample weighing several tons. This was cut down in the usual manner and the pulp assayed by the distillation method.

As no more than enough ore for one day's run was allowed to accumulate in the loading-bin, it was possible to calculate from which particular part of a drift the day's sample came and the number of feet it represented. This method of sampling in conjunction with the furnace-recovery for the entire sampling-period gave results that were higher than returns from channel-samples which previously had been taken at 5-ft. intervals over the same ground.

Mining Law

The Editor:

Sir—In your editorial columns of December 30, I see quoted Sec. 14261 of the California state mining law, which is there referred to as a much-needed provision, and under the head of 'Discussion' in your issue of January 13, 'Nil Desperandum' considers it a "bully" law. As a prospector who has followed the game for more than 34 years in practically all the Western mining territories and States, from Texas to Kotzebue Sound, from Mexico to Canada, I call it a super-freak. I consider the person capable of conjuring such a hybrid

fully entitled to a medal. So far as I know, California was the first State to hatch this disqualification egg; but since then its legitimate offspring, in a somewhat degenerate form, has invaded this beautiful northern land. I hope there will be room in the Hall of Fame for the originator, as well as the imitator of the above law. I will try to show from personal experience how Sec. 14261 works in practice. A few years ago I was prospecting in the Sierra Nevada, in California, where I discovered a promising so-called 'blind' gold-bearing vein, after driving an adit some 20 ft. into the alluvial overburden. It being then late in the fall, and as that section is noted for heavy snows, I was obliged to go out. As there was no outcrop, I located one claim only, taking the precaution, however, to cover as much as possible all evidence of mineral by caving the roof of the adit, and burying float, etc., intending to locate additional ground the following season, if further prospecting would justify. I then rushed out. Circumstances over which I had no control prevented me from returning the following season. When my three-year sentence of disqualification expired, I found myself in Nome. I may or may not see that prospect again. Some other prospector may discover it. If not, and if there is a mine cached there, the State is a loser. I am punished. Let the State kill this 14261 thing and require the prospector who re-locates his claim to expend at least \$300 in development work immediately after re-location to acquire title. Such a law would eliminate the claim-hog, benefit the State, and might occasionally be the means of bringing in a new mine, and at the same time punish the prospector.

NIGGER HEAD.

The Propeller-Agitator

The Editor:

Sir—In your issue of March 24, 1917, I notice a communication signed 'An Old Subscriber,' in regard to the Devereux propeller-agitator described in your article on the Nickel Plate mill at Hedley, and also by Roscoe Wheeler, superintendent of that mill.

'An Old Subscriber' quotes from an article in the MINING AND SCIENTIFIC PRESS of September 17, 1904, describing a similar agitator, for the expressed purpose of preventing any of your readers from believing that this is a new device. Unfortunately, the name of the author of the communication quoted is not given, and I have not a copy of the PRESS of September 17, 1904, available, but I believe the agitator described is the De-

vereux agitator, and is the same as that with which the Nickel Plate mill has recently been equipped. This agitator, which consists of a propeller revolving horizontally in a tank a sufficient distance above the bottom so that the settled solids do not interfere with starting and used in conjunction with a baffle-board to prevent the contents of the tank assuming a rotary motion, was invented by W. B. Devereux in 1902, for the purpose of agitating slime-concentrate at the mill of the Melones Mining Co., and patent was applied for in January 1904. These agitators have been used continuously by the Melones Mining Co. since that time, but notwithstanding that fact, they are comparatively new to the public, as until recently their successful application has not been generally known. Agitation by means of a propeller is not a new idea, but the combination of a propeller, so situated above the bottom as not to interfere with the starting by the settled solids, and a baffle-board, formed the novelty of the invention. The machines were built at one time by the now defunct Fulton Iron Works, and it is quite possible that the article in question originated with them, but in any event, whoever the author, it is probable that the article is a description of the original agitators installed by the Melones Mining Company.

WILLIAM G. DEVEREUX.

Melones, California, March 27.

[We do not doubt the correctness of Mr. Devereux's surmise. It is altogether likely that the description of the agitator in our issue of September 17, 1904, did come from the source indicated.—EDITOR.]

Bonus System in Milling

The Editor:

Sir—Referring to the letter in your issue of March 17 on this subject, I believe this should have been called 'Wrong Bonus System in Milling.' The writer of that letter stated the principles on which the bonus system was based and then pointed out the effect of the same, which, no doubt, proved disastrous. Any person who has had any experience with bonus systems could see at a glance that the principles of the one under discussion were wrong and that the effects of same could have been nothing but disastrous. According to your correspondent, the bonus system paid a bonus only to the mill-man showing the highest tonnage crushed and only to the mill-man who produced lowest-grade tailing. Bonus systems based on the principle that only the men who produce the highest results should be paid a bonus, in most cases, as in the case referred to, produce dangerous competition and eliminate true co-operative team-work of the various men on the various shifts, for the simple reason that in order to earn the bonus they must defeat individuals on opposing shifts and the human tendency is to try to produce this defeat by any sort of means available, whether they be legitimate or not. If any man discovers an improvement in the process whereby he can increase the output, it would be entirely to his disadvantage to let the members of the opposing crew

learn of this improvement, for then he would be really working against his own personal interest as far as receiving the bonus is concerned.

All successful bonus systems are based on the recognition of individual effort, but they are so designed and applied that they promote, rather than retard, co-operative team-work, and it is by the correct application of the right type of system that co-operative team-work is produced toward the ultimate prosperity of both the employer and the employee.

Sulphur From Pyrite

The Editor:

Sir—With interest I have read, in your issue of March 17, M. G. F. Söhnlein's inquiries regarding recovery of sulphur from pyrite, and your discussion of the problem is illuminating. Mr. Söhnlein is correct in his assumption that pyrite itself may be used as source of heat in the production of sulphur from this compound. In Sweden and other countries where native sulphur does not occur but where large quantities of pyrite are available, a simple method of production has been developed. A furnace similar to a small lime-kiln has been used. Grate-bars are placed in the bottom and the pyrite in large lumps is piled loosely upon them. To ignite the charge in the kiln a layer of wood and shavings is placed on the grate, by which the initial heat is developed. Once ignited, the kiln will burn continually. At a suitable height on the kiln-wall is an opening, by which the sulphur-vapor can be withdrawn and condensed. From time to time the cinder is drawn from the grate-bars and fresh pyrite charged at the top. It is reported, that a kiln operating in this manner delivers half of the sulphur present in the pyrite, while only one-third is obtainable when pyrite is heated in a closed retort. As to the manufacture of the calcium hyposulphite, it is a simple undertaking. Wooden towers from 30 to 90 ft. in height and 6 ft. in diam. can be used for this purpose. The towers are provided with heavy wooden grates in the bottom. These towers are filled with limestone. The sulphur di-oxide, produced by burning sulphur, is admitted at the bottom, while water is kept continuously trickling down over the limestone. Thus calcium hyposulphite is produced, which is stored in suitable vats. The limestone is gradually consumed and must be replenished from time to time. Neither of these chemical processes are novel. They have been in practice for many years. The above method of producing sulphur has been used for hundreds of years in Sweden, and the method described of producing hyposulphite has been employed ever since sulphite paper-pulp has been manufactured.

J. W. BECKMAN.

San Francisco, March 20.

GOLD PRODUCTION in Oregon last year amounted to \$1,861,796, being the output of 95 mines. The silver yield was 117,947 fine ounces.

THE ALASKA JUNEAU AND EBER MINES, ALASKA.

Methods of Mining Big Orebodies

By ROBERT A. KINZIE

INTRODUCTION. At the present time, there is a great deal of interest in the mining methods that are to be adopted in the mines on the mainland near Juneau, Alaska. This awakening of interest is due to the recent financial prominence of the Alaska Gold Mines Co. and the Alaska Juneau Gold Mining Co., and also to the magnitude of the proposed operations and the low cost of mining estimated by the engineers in charge of the work.

The operations of the Treadwell group and the stoping experiments made in the Perseverance mine of the Alaska Gold Mines Co. pave the way for the mining methods that will ultimately be used in all of the large low-grade ore deposits in what is known as the Juneau Gold Belt. The work done on Douglas island has made available a large number of accurate data of methods and cost that can be utilized as a guide when discussing the possible methods and costs of mining the ore on the mainland. There is one most important fact to keep in mind when using these data: that the problem of removing the ore from the mixed slate and meta-gabbro bands in the vicinity of Juneau is a much more difficult matter than that of mining the remarkably uniform and homogeneous diorite intrusions of the Treadwell and adjoining mines.

The importance of designing and operating a method of stoping that, while safe, will be cheaper than that in use on Douglas island becomes imperative when it is realized that the recoverable gold-content of the ore from

the Juneau belt is only about one-half that yielded by the ore of the Treadwell group.

The portion of the Juneau belt in which the principal mainland mines are situated extends from Sheep creek on the south to the valley of Salmon creek on the north, a distance of $5\frac{1}{2}$ miles. While the zone of mineralization has a maximum width of 3000 ft. the workable orebodies are confined to the foot-wall portion, with a maximum width of about 900 feet.

The rock forming the foot-wall of the ore-zone is meta-andesite, locally known as 'greenstone,' which has been converted into chloritic schist at the contact with the foot-wall orebodies. The ore-zone is composed of bands of altered sediments, locally called 'black slate,' which have been intruded by dikes of meta-gabbro. These dikes are generally parallel in strike and dip with the slaty cleavage. The dip varies from 65° , in the Perseverance and Alaska Juneau mines, to 35° , in the vicinity of Mt. Juneau. The meta-gabbro dikes, as well as the black slate of the foot-wall country, have been crushed and sheared, and the crushed areas are highly mineralized.

Both the black slate and the meta-gabbro are cut by numerous stringers or small lenticular quartz veins. When the sulphides of zinc and lead are present, the general rule is that the gold content of the ore varies directly with the proportion of quartz, but when the sulphides are absent, the quartz is usually barren. Undoubtedly there is a distinct genetic connection between

the ore and the meta-gabbro dikes. When the stringers of quartz extend into the black slate to distances of 30 or 40 ft. from the meta-gabbro dikes, the galena and blende disappear and the rock becomes too poor to be mined.

The ore-zone has been cut by several large faults, the Silver Bow fault, which crosses the Alaska Juneau ground, being by far the most important, both with respect to its magnitude and possible economic effect. Next in importance is the Nugget Gulch fault, which can be traced from the summit of the ridge dividing the basins of Sheep and Gold creeks to the bed of Gold creek, a short distance north-west from the Ebner workings. It is along the line of this fault that practically all of the known orebodies in the different mines are found. When the faults have black slate on one or both walls, the slate has been badly crushed, thereby forming a 'gouge,' or clay band, from 3 to 30 ft. wide. This gouge will be an important factor when stoping methods are to be selected.

Contrary to generally accepted ideas, the gold in the ore is not uniformly distributed, as in the diorite dikes of the Treadwell mines, but is confined to nearly parallel bands. The ore in these bands forms elongated lenses and the bands themselves are separated from one another by waste. The maximum width of the ore-lenses is from 10 to 100 ft., while the intervals of waste separating them vary from 30 to 200 ft. In the so-called ore-bands, there are numerous tongues of waste that will have to be mined with the ore. I do not think that the entire width of the ore-zone (say, 300 to 900 ft. wide) can be considered as 'ore,' nor can any scheme of stoping that includes the mining of it as a whole be conducted at a profit, on account of the large amount of waste-rock that will have to be handled.

Considering the ore-zone as differentiated from the mineralized zone, there is no distinct hanging wall. The gold-content simply fades as the distance from the foot-wall greenstone increases, resulting in an area of practically barren rock, made up of black slate and dikes of meta-gabbro between the ore-zone and the schist hanging wall of the mineralized zone.

The best method of stoping for any particular mine is the one by which the highest extraction of ore can be made at the lowest cost. Here the word 'stopping' is used in its broadest sense, and includes all necessary development and preparatory work.

In the mines near Juneau the low gold-content eliminates at the outset any consideration of those methods of stoping in which timber is used to support the ground.

In a broad sense the Juneau ore deposits can be considered as lodes—having an average dip of 55°—of known width, great length, and unknown depth. It will, therefore, be seen at a glance that they differ in the most essential details from the disseminated-chalcocite deposits of the West and resemble closely the ore deposits of the Homestake in South Dakota and the Treadwell in Alaska. A large proportion of the ore cannot, however, be mined by the methods in use in the two mines cited, for physical as well as economic reasons.

The stoping methods adopted will vary in the same mine on account of the physical characteristics of the ore, that is, whether the ground to be stoped is meta-gabbro, mixed meta-gabbro and slate, or slate. It is a fortunate coincidence that the gold-content of the different classes of ore varies directly with the probable cost of mining, and this means that the richest and most consistent orebodies are in the meta-gabbro, while the poorest and most erratic are in the slate.

As all of the known orebodies will be developed by means of adits driven at depths varying from 1000 to 2000 ft. below the outcrop, it is axiomatic that any method of stoping will depend for its success on the effective ventilation of, and easy access to, all the working-faces of the mine and the efficiency of the methods of transporting the broken ore from the stope to the mill-bins.

Before the work of 'blocking out' the ore and starting the stopes can begin, a raise or shaft should be driven to connect the adit with the surface. This shaft should be used only for ventilation and for the transportation of men and supplies, and be excavated—if possible—in the hard and tough meta-andesite of the foot-wall, thus ensuring its permanence and freedom from accidents on account of the movements of ground due to stoping operations. It is probable that the vertical distance between levels will vary from 200 to 300 ft., depending on the character of the ore to be mined, that is, whether meta-gabbro or slate predominates. This being the case, man-way-raises should be driven connecting the levels every 400 ft. As the raises are being driven, short intermediate drifts should be run at intervals of about 30 ft. These short drifts would connect with the stopes when they reach each succeeding intermediate level and would serve as man-ways. By running the stub-intermediate drifts when the manway-raises are put up, the danger of breaking ladders and pipes by blasting, when connecting from the stopes to the manway-raises, is obviated. If the main shaft is placed near the middle of the orebodies, the best position for the first raise to be used for transferring broken ore from the various levels to the main-haulage level is parallel with and about 50 ft. from the shaft. This ore-way need only be run to the top level. To avoid packing of ore in the ore-ways, the descent of rock should be controlled by by-pass gates at intervals of, say, 300 ft. If these gates are placed on each level and made part of the station ore-bin, much trouble and expense will be saved. It is quite probable that there will be some seepage of water through the ore-ways after the upper levels have been stoped and caved, so as to increase the liability of packs or hang-ups in the ore-ways. For this reason alone it is desirable that intervals not longer than 300 ft. should be allowed between the control-gates. If the ore-ways are driven in the foot-wall, it will be a simple matter to drain all the water from the upper stopes.

The gold-bearing meta-gabbro ore is a tough homogeneous material, free from cracks and slips when not in the close proximity to faults, and affording, therefore,

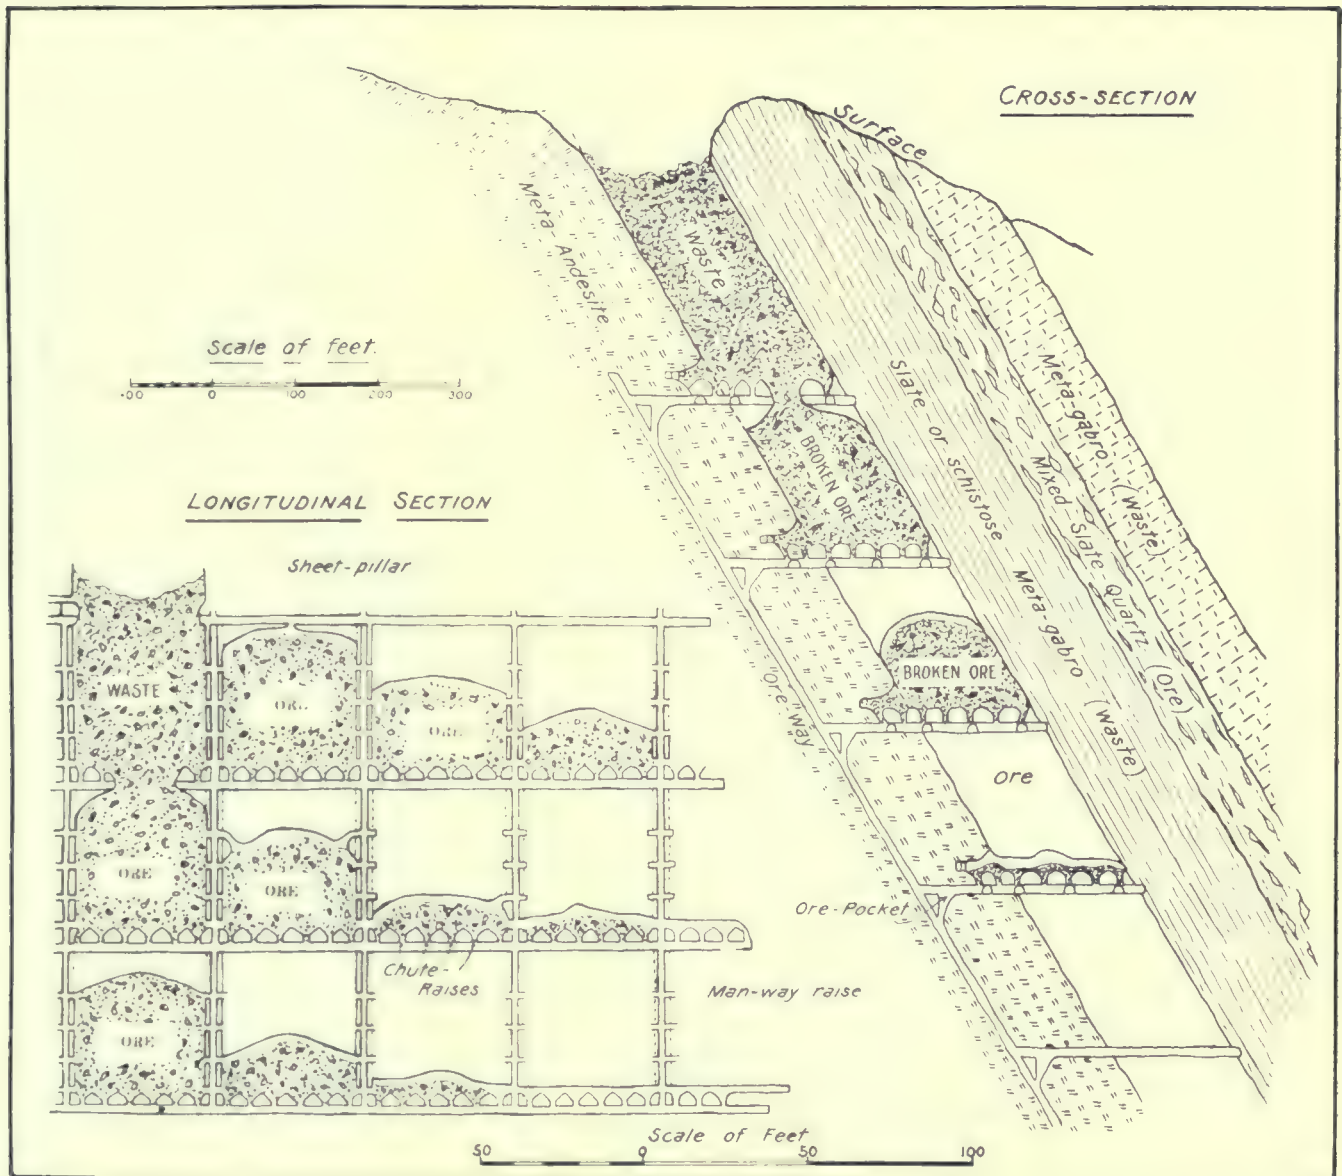

FIG. 1. SHRINKAGE METHOD.

excellent standing-ground. It will not cave or slough if ordinary care is exercised by properly trimming the stopes after blasting.

The methods used at Treadwell for stoping the ore and reclaiming the pillars are peculiarly adapted to the mining of the meta-gabbro ore, particularly when the 'bulldozing-chamber,' as now perfected, is considered as part of the scheme of mining.

It will be noted that in all the descriptions of stoping methods that follow, the so-called bulldozing-chamber is a most important factor. It was adopted in the mines on Douglas island to reduce the cost of bulldozing and sledging in the stopes and also to purify the air in the principal working-places, by reducing the fume due to blasting and also to cut down the number of men working in each chamber. Any mining engineer knows the lost time, accidents, and reduction of efficiency due to the above causes, and will be interested to know that the bulldozing-chamber has been the means of reducing the above evils to a minimum. This chamber can be used to ad-

vantage in conjunction with any of the various forms of the shrinkage or caving methods of stoping. It consists of a chamber cut in the foot-wall or in the sides of a stope, and is connected to a haulage-level by means of chute and man-way raises. The chute-raises are used to transfer the broken ore to the haulage-system and the man-way-raises for means of communication and ventilation. There should always be two means of ingress and egress to the chamber on account of the liability of a rush of rock blocking the passage to the man-way or ventilating raise. If there is but one means of communication, the chamber should be cut wide enough to insure a safe passage at all times. However, since good ventilation is such an important factor, two means of communication should be provided if possible. The side of the bulldozing-chamber facing the stope is cut away and connected with the stope throughout its entire length. The height and shape of the roof of the chamber, on the stope side, is regulated by the character of the ore handled and should be so proportioned that the broken ore in the stope will

flow freely to and over the entrances to the chute-raises. This allows the powder and block-hole men to work in a protected place, while breaking the large pieces of ore to the desired size. In the Treadwell mine, where caved ore is being handled, the bulldozing-chambers are from 50 to 100 ft. long, 20 to 30 ft. wide, and the height will vary from 9 ft. in the back part of the chamber to 50 ft. where it connects with the stope.

While describing various methods of stoping I shall ask the reader to keep in mind the fact that their ultimate success depends on the work being started on the top level and proceeding downward as the ore is exhausted, allowing the walls to cave and form a mattress over the broken ore below. Although they will permit of stoping to a limited extent from any level, the final success of the system absolutely depends on starting stoping at the upper portion of the orebody and working downward, not starting at the level of the main haulage-way and working upward. It would, of course, be possible after the shaft and ore-ways are completed to carry the stopes through to the surface from the main haulage-level, but this would tie up an unwarranted sum of money on account of the immense tonnage of broken ore that would remain in the stopes until the whole operation was completed. This tonnage would amount to at least 65% of all the ore broken, as it is only possible to draw off 35% of the broken ore and leave sufficient head-room for the men to work. Furthermore, in the slate stopes, a long continued exposure of the hanging wall to the air would cause it to cave, thus mixing with the broken ore a prohibitive amount of waste rock.

Even when the above suggestions are carried out, there are certain conditions and limitations that restrict the application of the shrinkage system of stoping and, to my mind, these conditions exist to a marked degree in the Juneau belt.

It is axiomatic that, before starting any form of caving or shrinkage stoping, there must have been completed an accurate survey and geological study of the orebody and that the permanent centre-line of all stope-pillars has been selected so that the pillars on each level will be in a vertical plane, no matter how deep the workings are carried. There is a great temptation to change the position of certain pillars on account of their containing ore richer than the average. The yielding to this temptation has been the most fertile cause of the failure of this form of stoping in a large number of mines.

Where wide bodies of ore are being extracted, the next most frequent cause of trouble is the failure properly to support the walls after the ore has been drawn. If the angle of dip is more than 45° the stopes can often be filled with waste from the surface by simply allowing the hanging wall to cave and follow down on top of the broken ore as it is drawn. This method works fairly well where the orebody is wide, down to a depth of 1000 ft., but it is extremely hazardous to depend on it for greater depths, because the filling has a tendency to pack and hang up—then, when a large open space has occurred, to let go suddenly and carry away all supports

in the stopes below. If the angle of dip is less than 45° the stopes will have to be filled by some other method.

When the dip of the orebody is less than 60° the efficacy of any shrinkage method of stoping is materially reduced and should not be adopted unless there are other conditions that offset those due to dip. There is a mistaken idea that the broken ore in a stope will flow freely to a chute or other opening. As a matter of fact the broken ore drawn through any one chute can be represented by a cylinder whose diameter is the same as the opening of the chute and whose height is the depth of the broken ore in the stope. It is for this reason that the chutes should be as close together as possible and that their openings in the bottom of the stope should be so flared that the stope-opening of any one chute would intersect those of its neighbors. Also when the dip is less than 60° the levels have to be run at shorter vertical intervals, and this added cost will often counter-act the economies of any shrinkage or a combination of shrinkage and caving method of stoping.

When proposing and describing the following methods of mining, as applied to the low-grade meta-gabbro slate orebodies in the vicinity of Juneau, I do not lay any claim to originality, but do say that, in their modified form, they are in my opinion suitable for the work for which they are recommended. This opinion is not based on theory alone, for all four methods have been tried in practice in a number of mines under my direction, and some of them, in a modified form, are now being extensively used in the district under discussion.

1. Shrinkage (as in use on Douglas island). For stopes in compact and uncrushed meta-gabbro. See Fig. 1 and 2.

2. Combined shrinkage and stoping and caving of pillars. For stopes in meta-gabbro where the ground has been somewhat crushed or faulted, or in mixed meta-gabbro and slate. See Fig. 3, 4, 5, and 6.

3. Combined shrinkage and caving of pillars. For stopes in crushed meta-gabbro or slate, when the ore will not stand exposure to the air without caving. See Fig. 7.

4. Combined shrinkage and caving. For stopes in heavy ground, where the foot-wall is good and well defined. See Fig. 8, 9, and 10.

FIRST METHOD. This method of stoping is applicable to the orebodies in compact and uncrushed meta-gabbro, lying next to the meta-andesite foot-wall and to a less extent to the more or less crushed meta-gabbro orebodies situated at a distance from the foot-wall, but having walls of fairly good standing rock. While the method can be used to advantage when the orebodies have widths of 30 or 40 ft., the most economical stoping-width is from 100 to 120 feet.

Since the dip of the meta-gabbro orebodies will average 55° , the most economical vertical distance between levels is taken as 200 ft. This spacing of levels can, of course, be changed to suit the varying conditions in the mine. If the distance is increased, it means a less development cost per ton of ore stoped, but on the other hand it ties up a larger amount of ore in the form of broken ore in

stopes for a time varying directly with the increase in the height of the stopes, because the miners employed in the stopes work on top of the broken ore and, since only 35% of the ore can be drawn and preserve the desired working conditions, it means that 65% of the cost of stoping must be charged against the broken ore remaining in the stopes until such time as the stope is carried up to the next higher level and completed, when all the broken ore can be drawn.

If the height of stoping is decreased, it means an increased development cost per ton of ore stoped, for the development and preliminary work is practically the same, irrespective of the distance between levels.

When the orebody has been reached and its width determined by a cross-cut from the main shaft, the first work is the connecting of the level with the main trans-

and the bulldozing-chambers, is in ore. In the Treadwell mine the dimensions of the drifts and cross-cuts are 7 by 9 ft. and the manway raises are 5 by 7 feet.

All the drifts should be connected by cross-cuts at intervals of at least 400 ft. In addition to furnishing ventilation, they afford an excellent opportunity for accurate sampling.

As the stope-pillars on each level are laid out so that their centres will lie in the same vertical plane, at right angles to the strike of the orebody, the position of the chute-raises is known and they should be put up as the drifts progress. The chute-raises are 5 by 6 ft. and run with an inclination of about 60°. The height of the raise depends on the thickness of the pillar left between the bottom of the stope and the level. As soon as the chute-raises are completed, the chutes are con-

FIG. 12. DOUBLE-TRUCK SIDE-DUMP CAR. CAPACITY 130 CU. FT.

fer-chutes or ore-ways and the starting of a foot-wall drift in opposite directions from the main cross-cut. It is of prime importance that the foot-wall drift be kept on the foot-wall, thus defining one limit of the orebody, for the reason that the position and direction of the other haulage-drifts and raises, as well as the intermediate drifts and bulldozing-chambers, are determined from it.

At intervals of 400 ft. manway-raises are put up from the foot-wall drift and connected with the next higher level. These raises are used as means of communication and ventilation, while the development work is in progress, and afterward as means of ingress and exit to and from the stopes. As the raises are driven, stub-drifts (15 ft. long) are run at intervals of 30 ft. and the manway-raises are equipped with permanent ladders, air and water-pipes, and station-platforms are built at the level of each stub-drift on both sides of the raise.

When the foot-wall drift is far enough advanced to determine the strike of the foot-wall, parallel drifts are started from the main cross-cut with 60 ft. centres. It is desirable to make these large, since all of the development work, with the exception of the foot-wall drifts

constructed. In the foot-wall drifts, the chutes are all on the foot-wall side and are spaced 20 ft. centres; in the other drifts and cross-cuts, they are spaced 30 ft. centres, but are put up from both sides of the drifts and are staggered, so that each interval is really 15 feet.

The work of stoping is started by driving a drift at the level of the floor of the proposed stope, from the manway-raise and connecting it with the top of the nearest chute-raise. This intermediate is continued until at least two or perhaps three chute-raises are connected. The intermediate drift is then widened out until the entire width and length of the stope is cut out and connections made with the tops of the chute-raises previously excavated. If the ground stands well, the chamber will average about 7 ft. in height—if the ground is bad, the roof is arched, the height and position of the arch depending on the character of the ground. As the cutting-out of the stopes progresses, the tops of the chute-raises are widened by machine-drills working on a tripod or by hammer-drills set up in the raise. Thus, the final shape of the chute-raise resembles a funnel, the outer edge of the rims of each parallel row of chute-raises in-

tersecting. This allows a larger area of the stope to be drawn from a single chute and greatly reduces the work of 'picking in' as the stopes are drawn. On account of the men working and blasting on the surface of the broken ore, it packs into a compact mass, and when it is drawn, it flows to the chute through a cylindrical space, the end area of the cylinder coinciding with the area of the top of the chute-raise, instead of the inverted cone that would be formed were the broken rock loose and free to flow. The stope is increased in height by drilling and blasting from the back and along the sides of the pillars.

The drilling can be performed by either reciprocating or hammer-type drills, the footage being the same for both classes of machines, but the cost is decidedly in favor of the hammer-type. Close attention and super-

with the regular drilling-crews and the added danger of a ragged 'back' and an increased number of men exposed to the risk of accident.

As the stopes grow in height, they connect in succession with the stub-drifts driven from the manway-raises at the time they were put up, and in the same order the lower stub-drifts are blocked with broken ore until such time as the surface of the broken rock again reaches its level in the process of being drawn from the stope after it has been carried up to the next higher level and completed. A detail of construction in connection with the manway-raises and stub-drifts that has an important bearing on the drilling efficiency in the stopes, is to carry the main compressed-air pipe *down* the manway-raise, leaving a connection opposite each stub-drift, instead of up the manway-raises, as is ordinarily done. When the pipe comes down the raise, any water in the air can easily be drawn off at the bottom end and, as the stope gains in height, the lower sections of the pipe can be removed and used in other places. Also the danger of broken pipes, due to blasting in the stopes or to objects falling down the shaft, is greatly reduced.

The work of stoping by blasting down the back, breaking up the larger pieces of ore and drawing off one-third of the broken ore, is continued until the apex of the arched back of the stope breaks through into the next higher level. The method of breaking through from an uncompleted to a completed stope is clearly shown in Fig. 1. The machine-drill men work from the centre of the stope in all directions toward the walls under the protection of the sheet-pillar, gradually enlarging the opening between the stopes by drilling inclined holes and blasting the ore from the sides of the opening until about 85% of the ore left between the bottom of the level and the sill-floor of the stope above has been recovered.

In some instances, it may be possible to recover the stope-pillars, but on account of the low grade of the ore and the danger attached to its removal, it may be found more economical to leave them in place.

If the hanging wall is good enough to prevent caving while the stope is being carried up, it is possible to recover about 75% of the ore by this method of stoping.

After the stope has been connected with the next higher level, all the broken ore in the stope can be drawn, thus allowing the broken waste that caves from the walls to fall on top.

The proportion of broken ore in the stopes that can be drawn through the bulldozing-chambers and stope-chutes will depend on the dip of the foot-wall, but in any event there will be a small proportion of the broken ore that will not be recovered until the stope from the next lower level breaks through and the bottom of the stope is removed. In the Treadwell mine a large part of the broken ore in the corners and between the chutes is shoveled into the chutes, but it is dangerous work and I am doubtful if it will be found economical to follow this method in the mines on the mainland.

(To be Continued)

FIG. 2.

vision should be given to both the recorded results and the manner of performing the drilling, and the men in the mine should know the results of not only their own work, but of similar work in the same mine or elsewhere. The holes should be drilled to a depth of about 7 ft. and be so pointed that the bottom of the hole will be about 3 ft. from the back of the stope. These dimensions will vary from week to week in the same stope and the miner will learn from experience the best-breaking depth for any particular rock. The holes should be drilled at a fairly flat angle, for the object is not only to break a large tonnage of rock, but to so blast it down that it will break in pieces that can readily be handled either in the stopes or bulldozing-chambers. The unaltered metagabbro is an exceedingly difficult rock to break with hammers. It is, therefore, advisable to so regulate the drilling and blasting that only such pieces of rock as will readily pass through the stope and thence into the bulldozing-chambers will be excavated. If large masses of rock are broken, it means more men in the stope and more powder-fume, to say nothing of the interference

The Engineer Enlisted Reserve Corps of the United States Army

The Engineer Corps in our army corresponds to the famous Royal Engineers of the British army, that branch of the service which builds roads and bridges, fortifications for defense and tunnels for offense, and various other duties. To them is due the wonderful system of field-fortifications that enabled the British to withstand

Topographical draftsmen are wanted to trace the field-maps of surveyors. Mechanical draftsmen will find employment in making drawings of armored trains, armored trucks, and other mechanical devices used in war. Photographers are needed for the reproduction of maps in connection with photographic surveys.

the enemy's onslaught during the last two years and a half. The United States of America is now at war and there is no time to train engineers for such work; the men of the Engineer Corps for the new armies must be taken from the ranks of civil, mining, mechanical, and electrical engineers, as well as machinists and other skilled trades.

The Engineer Corps of the army needs topographical surveyors, sketchers, and instrument-men for the highly important technical work of making contoured military maps of the field of war, laying out battle positions, roads and highways, systems of trenches, and drainage lines.

Lithographers, zincographers, blueprint-men, and others skilled in the various processes of reproducing photographs and drawings, are required to reproduce and publish engineer-maps of battlefields and the general theatre of war operations.

Miners and quarry-men skilled in handling explosives and in underground-mining form one of the most important elements in the personnel of the Engineer Corps. The engineers dig the tunnels under the enemy's trenches and destroy them with dynamite and other high explosives. They dig the underground galleries and bomb-proofs that conceal and protect the armies occupying their own trenches.

. Military demolitions such as the destruction of bridges, bridge-piers, railroads, and road-beds, as well as land-mines, are effected by the Engineer Corps.

Carpenters and woodworkers of all classes are needed for the timberwork in trenches and bomb-proofs.

Millwrights and bridge carpenters are especially valuable in the construction of bridges, which the Engineer Corps must build rapidly and of sufficient strength for the passage of army trains, great guns, and for the rapid transport of marching troops over streams and ravines.

Blacksmiths handle the ironwork, including the manufacture of forgings of various kinds in connection with bridge-work, trench-work, military demolitions, and also in the repair of entrenching tools, which the Engineer Corps is called upon to supply to the fighting army.

Plumbers and pipe-fitters lay the pipes in connection with sewage and water-supply systems for the trenches and fieldworks.

Electricians wire the trenches for electric lighting, operate the electric-light plants and power-plants, and operate the great search-lights and other electric illuminating devices used to light the area in front of the trenches. The electrification of barbed-wire entanglements forms a vital element in the defence of modern trenches. For this work electricians are required. Steam and gas-engine operators, fire-men, and machinists are needed in connection with the construction and operation of power-plants, steam and electric pile-drivers, the great caterpillar-trucks, and machine-shops.

Axe-men and millwrights work on the spar-bridges and clear space in front of trenches of trees, brush, wire entanglements, and timber structures.

Boat-men, riggers, and caulkers handle the floating bridge-equipage, which engineers carry in their trains and with which they bridge the widest streams.

Masons and concrete-men construct the permanent work on trenches and gun emplacements, sewage-lines, water-supply, and revetments.

Horse-shoers, farriers, packers, teamsters, and saddlers are needed in connection with the operation of wagon-trains and pack-mule outfits. Every engineer company has a section of 24 mounted men, and these, of course, are picked from among such as know how to ride and understand handling horses or mules.

Clerks, of course, are needed also, as there is a vast amount of clerical detail.

Cooks and assistant cooks are a vitally important element, for obvious reasons, in the personnel of an efficient and contented engineer company.

Musicians and signal-men are needed in every company to blow calls, act as messengers, and do the signalling.

There is hardly a phase of civil engineering-practice that is not carried on during the operations of a company of the Corps of Engineers in war-time.

The illustrations shown herewith are actual photographs of military engineering work conducted by the Corps of Engineers in the field.

The classes of men required may be briefly summarized as follows:

- a. Topographical surveyors and sketchers, including instrument-men
- b. Draftsmen, topographical and mechanical
- c. Photographers and blue-print men
- d. Lithographers and zincographers
- e. Quarry-men (skilled in explosives)
- f. Miners
- g. Skilled carpenters
- h. Bridge-carpenters
- i. Blacksmiths
- j. Plumbers and pipe-fitters
- k. Electricians
- l. Enginemen, steam
- m. Enginemen, gas
- n. Fire-men
- o. Machinists
- p. Masons
- q. Caulkers
- r. Riggers
- s. Expert axe-men
- t. Boat-men
- u. Horse-shoers
- v. Farriers
- w. Packers
- x. Teamsters
- y. Saddlers
- z. Cooks
- aa. Assistant cooks
- bb. Clerks
- cc. Musicians
- dd. Signal-men, as required by Army Regulations

An Engineer Company is composed of 109 engineer-soldiers, graded as follows:

3 Sergeants, 1st Class	1 Horse-shoer
1 Supply Sergeant	2 Buglers
12 Corporals	1 Mess Sergeant
2 Cooks	6 Sergeants
59 Privates	1 Saddler
1 First Sergeant	19 Privates, 1st Class
1 Stable Sergeant	

Sergeants must be at least 30 years old and have sufficient education to perform the duties of the grade, and must hold, in civil life, a position equal to or of the same importance as overseer in the Engineer Department of the Army, and shall be expert in one or more of the special qualifications listed above.

Corporals must be at least 25 years of age and must hold, in civil life, a position equal to or of the same importance as foreman in the Engineer Department of the Army, and shall be expert in one or more of the special qualifications listed above.

Privates must have one or more of the qualifications in the trades listed above.

The rates of pay are as follows:

	Per month
Master Engineer, senior grade	\$75
Master Engineer, junior grade	65
Regimental Sergeant Major	45
Battalion Sergeant Major	45
Regimental Supply Sergeant	45
Battalion Supply Sergeant	45
Color Sergeant	36
Sergeant Bugler	40
First Sergeant	45
Mess Sergeant	36
Supply Sergeant	36
Stable Sergeant	35

	Per month
Sergeant, 1st Class.....	\$45
Sergeant	36*
Corporal	24
Cook	30
Bugler	15
Horse-shoer	30
Saddler	21
Wagoner	21
Private, 1st Class	18
Private	15

In addition to the pay, all subsistence, equipment, uniforms, and transportation are furnished by the Government.

The War Department desires to secure immediately a large enrollment of enlisted men in this Corps. All enrollments are desired for war service and none will be accepted for less than the period of the War. The recruiting office for the Engineers Section Reserve for Central California is at 204 Pine street, San Francisco, California, and is open every day, including Sunday, and until late at night. As soon as qualified men are enlisted, they will be assigned tentatively to engineer companies, whose personnel will be called later into active service, armed, equipped, and trained as their services are needed at the front. Ten thousand engineers should be raised in California alone, and of these a large number should be secured from among those engaged in engineering and similar occupations in the vicinity of San Francisco bay. Suitable men are urged to make application, either by mail or in person, to one of the following officers:

- District Engineer Officer, 204 Pine St., San Francisco.
- District Engineer Officer, 723 Central Bdg., Los Angeles.
- District Engineer Officer, 602 Burke Bdg., Seattle.
- District Engineer Officer, First District, 806 Couch Bdg., Portland.
- District Engineer Officer, Second District, 321 Custom House, Portland.
- District Engineer Officer, Third District, 405 Custom House, San Francisco.
- District Engineer Officer, Eureka, California.

or, to any officer of the Engineer Section of the Reserve Corps, who have already been commissioned or recommended for commission, all of whom are authorized to secure applications.

The following is a list of reserve engineer-officers residing on the Pacific Coast already commissioned or recommended for commission:

CALIFORNIA

- Major Seeley W. Mudd, 2232 Harvard Boulevard... Los Angeles
- Major Geo. S. Binckley, Central Bdg..... Los Angeles
- Major Wm. A. Cattell, Foxcroft Bdg..... San Francisco
- Major H. H. Wadsworth, 405 Custom House.... San Francisco
- Capt. Carl A. Heinze, 1415 W. 49th St..... Los Angeles
- Capt. John A. Griffin, 428 E. 52nd St..... Los Angeles
- Capt. F. J. Fitzpatrick
- Capt. Walter H. Adams, 1661 Rose Villa St..... Pasadena
- Capt. K. D. Schwendener, 2158 W. 29th St..... Los Angeles
- Capt. J. L. Bacon, 1101 American Nat. Bk. Bdg..... San Diego
- Capt. Delmar S. Clinton
- Capt. C. R. Adams, 912 Griffith-McKenzie Bdg..... Fresno
- Capt. Carl E. Grunsky, Jr., 57 Post St..... San Francisco

- 1st Lt. William Hague Grass Valley
- 1st Lt. C. A. Meyer, 633 W. 18th St..... Los Angeles
- 1st Lt. Ross Henry Rock, 1443 W. 37th Drive..... Los Angeles
- 1st Lt. C. C. Bartlett, P. O. Box 308..... Corona
- 1st Lt. Kirby B. Sleppy, 1019 Florida St..... Los Angeles
- 1st Lt. Earl W. Fassett, 723 Central Bdg..... Los Angeles
- 1st Lt. E. E. Schliwen, 927 Gratten St..... Los Angeles
- 1st Lt. D. J. Young, 935 6th St..... San Diego
- 1st Lt. Wm. P. Belcher, 405 Custom House..... San Francisco

- 2d Lt. R. F. Dean, % Pacific Power & Light Co..... Seattle

SULPHATE OF AMMONIA to the extent of 500,000 tons per annum could be recovered from the coal now being coked in bee-hive ovens in this country, by the general adoption of by-product coking. The waste of materials useful for munitions of war as well as for constructive industry through the continuance of bee-hive coking in America may be appreciated when it is realized that the present loss of these valuable products exceeds the total consumption of such material by Germany in the war she is waging.

ZINC SULPHATE is not only a preservative of wood, but also of leather and other organic matter. A practical use of it is to saturate the soles of shoes and boots with a moderately strong solution of the salt. Thus treated the sole-leather resists wear to an extraordinary degree. Fabrics saturated in zinc-sulphate solution and then dried are resistant to fire, that is, though they will char on being heated, they will not transmit the flame by becoming ignited.

Characteristics of Magmatic Sulphide Ores

By C. F. TOLMAN, Jr., and AUSTIN F. ROGERS

*The term 'magmatic deposit' should be limited to segregations of ore-minerals that take place under the influence of, or closely connected with, the molten stage of the parent rock. Ore deposition accompanied by destructive pneumatolytic action, or when formed by the agency of hydro-thermal solutions, is not to be classified as magmatic, even though closely related to or closely following the magmatic period. The latter class of deposits is connected with acid rocks, while the typical magmatic deposits are confined to basic rocks. Contrary to general opinion, the magmatic sulphides are formed by replacement of the silicates after the solidification of the igneous rock. Notwithstanding this, the term 'magmatic ore deposits' is retained for the types of ores described in this paper, because they have a close genetic relation to the intrusive rock in which they occur, and because they are formed within the magmatic stage as herein defined. Regardless of any theory as to their genesis, however, these deposits have definite and easily recognizable characteristics, which distinguish them from all other types of ore deposits. The characteristics of the magmatic sulphide ores, as brought out by our study, may be summarized as follows:

(1) They occur in sub-silicic rocks of the norite, gabbro, peridotite, or related families.

(2) In most occurrences the containing rock is either dominantly sub-silicic, with minor amounts of complementary per-silicic differentiates (Insizwa), or occurs as lenses of mafic rock in a large granitic intrusion (Golden Curry).

(3) The sub-silicic rock occurs generally as small dikes, sills, or stocks, and rarely as a large laccolith (Sudbury).

(4) In most cases the ore-bearing rock has undergone marked differentiation, and the differentiated portions are sharply separated and do not grade into each other (Ookiep).

(5) The ore may occur in any variety of rock produced by differentiation, but in any one locality the ore shows marked preference for certain types of rock, and occurs sparingly in others (Ookiep).

(6) Pegmatite and aplite dikes often cut, and are therefore later than the orebodies (Erteli).

(7) The ore is generally segregated at the margins of the intrusives, but occasionally occurs as lenses or tabular ore-shoots well within the intrusive magma (Engels). In sills, the ore is usually at the base of the intrusives (Insizwa); in dikes, it often is formed along

the foot-wall (Sohland), or as columnar or irregular shoots occupying the entire width of the dike (Copper Cliff).

(8) Very often the ore is concentrated in those portions of the intrusive which have suffered brecciation during intrusion (Sudbury).

(9) The ore migrates only a short distance into the adjacent rock, from a few inches to a few score of feet at most (Sudbury).

(10) The 'offset' deposits, formed in dikes at some distance from the main intrusive, are accompanied and cut by veins carrying ore and gangue minerals of hydro-thermal origin (Sudbury).

(11) There is no essential distinction between the sulphide group and the magnetite-ilmenite group as to the origin or the relation of the ores to the silicate minerals. In all the magmatic ores examined, ore deposition takes place at the close of the magmatic period.

(12) There are two general classes of the magmatic sulphide ores: (a) pyrrhotite-chalcopyrite deposits, and (b) chalcopyrite-bornite deposits.

(13) The so-called pyritic intrusive ores are not magmatic.

(14) The principal ore-minerals of the magmatic period include magnetite, ilmenite, hematite, pyrrhotite, pentlandite, chalcopyrite, and bornite.

(15) Pyrrhotite and bornite have not been found together in magmatic ores.

(16) Pyrite is not a typical magmatic mineral.

(17) The ore-minerals are formed at a late magmatic stage by a partial replacement of the silicate minerals. The ores surround, embay, and cut all the earlier silicates. They penetrate the cleavable minerals. They occasionally occur as sharp veinlets which lead out from the larger sulphide masses. Selective replacement is shown by the preservation in the ores of an original graphic texture of the rock.

(18) There is a definite order of formation of the principal magmatic ore-minerals. This order is as follows: magnetite-ilmenite (intergrowth), hematite, pyrrhotite, pentlandite, chalcopyrite, and bornite.

(19) There is evidence of the replacement of one magmatic ore-mineral by another.

(20) Euhedral magnetite and probably other minor accessories occurring in euhedral crystals, such as apatite, zircon, titanite, etc., are also formed at a late magmatic stage.

(21) There is clear evidence of the magmatic alteration of pyroxene to hornblende prior to the introduction of the ore-minerals.

(22) Hydrothermal alteration, although seldom lack-

*Abstract: 'A Study of Magmatic Sulphide Ores,' 76 pp., 20 plates and 7 text-figures; Leland Stanford Junior University Publications, 1916.

ing in magmatic ores, is relatively insignificant, and is distinctly later than the magmatic ore period. The silicates of the hydrothermal period include tremolite, anthophyllite, sericite, chlorite, and serpentine. These secondary silicates often replace the magmatic ore-minerals in veinlets and in sharp lath-shaped crystals without causing any change or migration of the ore-minerals.

(23) The attention given these alteration-products in order to determine their relative age, may have produced an erroneous impression as to their relative abundance. In most of the ores studied they are present only in minor amounts. Many of the magmatic ores are as free from alteration products as the average unmineralized igneous rock.

(24) A minor amount of rearrangement, however, consisting in the production of microscopic crystals of pentlandite and chalcopyrite of the second generation, has been detected in the pyrrhotitic ores. In the chalcopyrite-bornite ores there has been some migration, resulting in the formation of minor amounts of covellite, chalcocite, and chalcopyrite of the second generation. This alteration is only prominent where there has been an abnormal development of sericitization.

(25) The rôle of mineralizers in magmatic differentiation has not been sufficiently emphasized. The crystallization of the early-formed minerals in the magma involves the complementary process of the 'squeezing out' of the residual fluid. This process is not merely a mechanical one, but is also due to gaseous extraction.

(26) The typical magmatic deposits, unaccompanied by high-temperature alteration, with the exception of magmatic hornblende, are chiefly developed in basic rocks. Ore deposits genetically related to per-silicic rocks show intense rock alteration, probably the result of mineralizers more active than those accompanying the sub-silicic rocks.

(27) There is a parallelism between the various groups of high-temperature deposits, of which the magmatic ores are one division. In all groups, high-temperature silicates precede the introduction of the ore, and hydrothermal stages follow. In contrast with the magmatic deposits, the non-magmatic ores are characterized by a complex set of pre-mineral silicates, and the hydrothermal stage is generally the most important period of ore introduction.

(28) The temperature at which the introduction of ore-minerals is initiated is about the same for all the high-temperature deposits; probably not higher than 300-400° C.

(29) Gradations between the typical magmatic ores and other high-temperature deposits are shown by the local development of garnet and tourmaline. Further, the gradations of these into intermediate-temperature and low-temperature deposits is strong evidence of the magmatic origin of ore deposits in general.

(30) The following orderly series of events is recognized in magmatic deposits:

- (a) Crystallization of primary silicates;
- (b) The development of hornblende and biotite, and

occasionally tourmaline and garnet, as magmatic-alteration products;

(c) The introduction of the ore-minerals;

(d) A small amount of re-arrangement of the ores and the development of secondary silicates by hydrothermal solutions.

Canadian Mining Regulations

The Governor-General-in-Council has issued an order affecting mines during the existing War, the essentials of which are as follows:

1. No assignment of any right in waters, lands (mining or other) may be permitted except to persons who were at the beginning of the War subjects of Great Britain or citizens of the Allied Powers.

2. In case of transfers of this nature through error or fraud, they shall be void and any fees paid shall be forfeit.

3. No company other than those of Great Britain or Canada may acquire or hold any such rights. The restriction extends to companies controlled directly or indirectly by foreigners.

4. No changes may be made in the articles of association, constitution, or by-laws of any company without consent of the Minister of the Interior. Infraction of this regulation will result in declaring the company to have ceased to be a British company, and in forfeiture of its rights, powers, and benefits.

5. Prescribes the procedure for cancellation of the company's rights by the Minister of the Interior.

6. Provided always that where any entry was granted for Dominion lands, or where any grant of any right, power, or benefit hereinbefore referred to was made before the passing of the order in council of the 14th day of December, 1916 (P. C. No. 2614), to a person who, after the passing of the said order in council, would have been debarred from making entries or acquiring such right, power, or benefit, a patent may be issued in the case of Dominion lands, and a lease, license, or certificate, as the case may be, may be granted for such right, power, or benefit in ordinary course upon proof being submitted in each case that the conditions requisite for the granting of such patent, lease, license, or certificate, as the case may be, have been fulfilled and performed, and, in the case of Dominion lands, upon evidence being also furnished satisfactory to the Minister of the Interior that the holder of the entry is a British subject.

IRON ORE to the extent of 200,000,000 tons has been estimated by geologists and engineers to be available in Canada, the greater part of which, however, is low-grade. The annual production of iron ore in Canada is about 400,000 tons, and its present blast-furnace capacity is 1,500,000 tons yearly, though the actual output of the Canadian iron-furnaces is about 1,000,000 tons. About 75% of all the iron and steel, and iron ore as well, required in Canada is imported.

The Nature of Chromic-Iron Deposits

By SAMUEL H. DOLBEAR

The following paragraphs are written with the hope that they may help the miner of this mineral to understand the nature and occurrence of such deposits. Fortified with this information he may better judge the advisability of prospecting certain areas, and furthermore there will be less likelihood of over-estimating the quantity of ore when only outcrops and other superficial evidence are visible.

It seems remarkable that so few miners of chrome ore understand the character of the deposits. I think that in most cases the miner considers he is opening an ore-body occurring in more or less irregular veins, and that the origin of the ore is similar to that of quartz veins. Outcrops may be found for a distance of several hundred feet, and in such alignment as to give the impression that the deposits are continuous. The handy pencil is then put to work to calculate that the average width of the orebody is, say, 11 ft., the 'vein' can be traced for 800 ft., and the ore ought to persist at least 20 ft. below the surface, giving, therefore, a total of 176,000 cu. ft.; which, at 10 cu. ft. to the ton, makes 17,600 tons of ore. This amount is then offered for sale.

So many estimates of tonnage based on such false hypothesis have been submitted to me, that I have had to establish the safety-first rule of catechizing each miner. His conception of the origin of chrome deposits determines, in a large measure, the accuracy of his estimate. This misunderstanding is not confined to miners alone; I have on file many reports made by those who choose to call themselves engineers, in which the same error is made. In one which was recently sent me the writer of the report became enthusiastic because "the formation had been broken by movement of the rocks thereby creating large channels through which the groundwaters could circulate, depositing chrome ore on their walls!"

ORIGIN OF CHROME DEPOSITS. To understand why estimates of chrome cannot be prepared in the above manner, it is necessary to know something about its origin.

When two substances, one of which is more soluble than the other, are dissolved in water, and the water is then evaporated, the least soluble substance will crystallize out first. During the period when the earth's crust was forming, chrome was in solution, not in water, but in the molten magma which formed rock on cooling. Chrome being more insoluble than other substances present, was one of the first materials to crystallize from the magmatic solution. During this crystallization, the particles aggregated in irregular masses due to a force known in nature as cohesion. When the cooling process was complete, and the entire mass was solidified, these

irregular bodies, which are designated lenses, were probably near the bottom of the formation in which they are found. As the weight of chrome ore is much greater than that of the rocks in which it occurs, it seems probable that it settled near the bottom during its aggregation. If this is to be accepted as correct, the question arises, "How did it reach the surface?" Folding, fault-

Fig. 1

Fig. 2

Fig. 3

■ Chrome Ore

ing, and weathering are the forces responsible for its exposure to the surface.

In Fig. 1 the lens of ore is shown in its normal position on cooling; later folding resulted in the mass assuming the position shown in Fig. 2; dynamic agencies, including erosion, resulted in conditions such as appear in Fig. 3. The dotted lines indicate the former position of

the rocks that concealed the deposit as shown in Fig. 1 and 2. The dark portion represents the consolidated mass of ore, surrounded by smaller bodies and segregated particles, which, attracted toward the main orebody, have not reached it because the progress is impeded by gradual solidification of the magma into solid rock.

All chrome miners are familiar with the gradual increase in the amount of waste-rock in their ore as the limits of their deposits are reached. Occasionally a deposit is found in which the line between the ore and wall-rock is distinct, sometimes separated by 'gouge' or 'miner's tale.' When no chrome ore is found in the wall-

ium is more soluble in basic than in acid magmas.

DISTRIBUTION OF CHROME IN CHROME DEPOSITS. All parts of chrome deposits are not of equal grade. The question has been asked, "What may be expected to be the highest grade?" In most deposits the ore near the walls or bottom is less pure than that in the main ore-mass. In the latter, however, there is much variation; and there is no rule to follow concerning its chrome-content. This irregularity is probably due to minor influences during the period of formation. The principal impurity is not necessarily silica; it may be iron, magnesia, or alumina. If iron be present as magnetite, the ore may be heavy and black, and appear to the eye to be

CHROME ORE IN MAGNESITE

VAUGHN CHROME OUTCROP

rock immediately adjoining the orebody, and gouge is present, it may indicate that the original wall-rock has been removed by displacement. The ore along the wall may be fluted or grooved, and if the disturbance has been sufficient, the orebody may be coarsely fractured, or even so finely crushed as to make it friable in the hand. Otherwise, if no chrome is present in the wall-rock, it may be due to earlier genetic causes. Some magmas were undoubtedly more fluid than others, just as some smelter slags run freely while others are so sluggish that they freeze readily at the tuyeres. In a particularly fluid magma there would be flow-currents just as there are in water, these tending to carry away chromite particles which had not yet consolidated with the main chrome mass. For this reason I conclude that the largest chrome deposits were probably formed in magmas relatively free from flow currents.

Chrome ore, when found, is always present in basic-igneous rocks, such as peridotite or its altered form, serpentine. This is probably due to the fact that chrom-

high-grade, yet be low in chromic oxide. Some good ore is found with a film of magnesium carbonate, so that it is white in appearance, and such ore has been condemned because, for that reason, it was considered to contain too much silica. It is important to remember this: "you cannot make an optical analysis of chrome ore."

FIELD DETERMINATION OF CHROMITE. Familiarize yourself with the appearance of typical chrome ore. Scratch a piece of the suspected ore with a knife, deep enough to penetrate any surface film of foreign material. If the streak is dark-brown, the material may be chrome.

If the prospector will provide himself with a spirit lamp, two inches of platinum wire (fixed in a short glass tube) and an ounce of borax, he can make a fair determination. The operation is as follows: Crush a small piece of the ore with pestle and mortar. Bend a small loop at the end of the platinum wire. Heat the wire a moment in the flame, and dip in the borax. Some borax will stick to the loop. Melt this in the flame and continue dipping in the powdered borax and melting until

the loop has become filled with a bead of colorless borax-glass. Heat the bead to redness, and while hot place it against the crushed ore until a few particles adhere to the bead. Hold this in the flame until the particles are entirely dissolved in the borax and allow to cool, when the bead, if chrome is present, will have a bright green color. Having determined that chromium is present, send the sample to a reputable chemist and ask him to determine chromic oxide and silica. The ore-buyer must know the percentages of these two materials before he goes further.

MARKETABLE ORE. To be readily salable chrome ore should contain at least 40% chromic oxide (Cr_2O_3) and not less than 8% silica (SiO_2). Some ore is sold which carries not more than 30% Cr_2O_3 ; sometimes SiO_2 as high as 10 to 15% is permitted. Ore containing 40% Cr_2O_3 is more satisfactory in fire-brick manufacture than 30 or 50% ore. When other grades are purchased they are sometimes crushed and mixed with higher or lower grades, as may be required, to secure a 40% product.

Chilean Smelter to Handle Bolivian Tin

A stock company under the name of *Compañía Chilena de Fundición de Estaño* (Chilean Tin Smelting Co.) has been organized with a paid-up capital of \$243,000 for the purpose of establishing a smelter in the port of Arica, Chile, to treat tin concentrates from Bolivia. The committee of engineers having charge of the installation of this smelter is composed of Guillermo Yunge, Durward Copeland, and Richard Gabler. Tin ingots 99.75% fine will be made. It is said that the plans include the treatment not only of tin concentrate but of other minerals, and the ultimate installation of a manufacturing plant. The work is being done for the owners of the Llallagua Tin Co., Sr. Gigliotto, manager, Santiago, Chile. The capital is Chilean. The mines are at Llallagua, Bolivia, and form one of the two largest groups of tin mines in that country, the other large one being Patino. Durward Copeland, one of the engineers, is an American, formerly professor of metallurgy at the Missouri School of Mines. He has traveled in Cornwall, China, Straits Settlements, and Bolivia, gathering data. He is now at Arica, Chile. Construction has been started, the Chilean government assisting the company with grants of land and water rights.

TRINITROTOLUOL and picric acid explosives can be manufactured at a cost about 40% less than nitroglycerine. From this circumstance J. R. Mardick, writing in *Metallurgical and Chemical Engineering*, points out the probability that the manufacturers of these nitro-aromatic explosives will dominate the market for blasting compounds after the War. This would cheapen mining operations. The enormous increase in by-product coking since 1914 renders this assumption highly probable, since the raw materials for 'T.N.T.' and picric acid are derived from that process.

Aid to the National Cause

By courtesy of the Utah Metal & Tunnel Company, we have received a copy of a telegram sent to Beer, Sondheimer & Co., in response to an invitation from the latter (who are the Utah company's metal-selling agents in New York) to meet Mr. Bernard Baruch with reference to the selling of their product to the Government.

Boston, April 5, 1917.

Messrs. Beer, Sondheimer & Co.,

61 Broadway, New York.

Dear Sirs—

We confirm to you our telegram of April 5, 1917, as follows: "We do not like the appearance of dealing with our national government through an intermediary. To us it is amazing that the copper producers of this country are so blind to their own interests and that of their stockholders as to make an offer of sale to the Government that permits them to exist. We read in the newspapers that the copper producers of the country have agreed to sell their own Government about 3% of their annual production for 16½ cents per pound. We expect soon to hear that our soldier-boys will be offering their blood at about this price per quart. We therefore make this proposition: That we will give to the national government 3% of our copper product for this year and a larger percentage if a substantial proportion of the copper producers of the country will agree to the same terms and that we will likewise give to the national government a like percentage of our lead product, provided a substantial proportion of the lead producers of the country will join, without any price; and if the lead and copper producers of the country see fit to enlarge this percentage as a gift to the Government we will gladly join with them in increasing the proportion of our offer. We will comply with this proposition upon the request of the War or Navy department. We feel that this is an excellent opportunity for the corporations of this country to give the lie to the slanders which they have been under for many years, and we have not that faith in men that we can clearly discern how much short selling of copper stocks will be based on this thimble-rigging of mining companies by people who are willing to snuff the battle afar off provided they can short the stock market."

Very truly yours,
UTAH METAL & TUNNEL COMPANY,
(Signed) WILLIAM E. L. DILLAWAY,
Secretary.

EXPLOSIVES for blasting rock ahead of a steam-shovel when the ground is wet should preferably be a low-freezing gelatin from 40 to 60% strength. Existing prices of glycerine being high, contractors find that good results can be obtained by using lower-grade explosives where higher grades were formerly thought necessary. If the work is dry a low-freezing dynamite can be used. In tight, hard bottom gelatin is best because, in addition to the advantage of not needing to be thawed, it combines density with high water-resisting power. Density is an advantage in that more weight of explosive can be concentrated in the bottom of a bore-hole of any given diameter than when lighter grades of dynamite are used. For sub-aqueous rock-blasting, a 75% strength gelatin-dynamite is best adapted. Nothing weaker than a No. 8 electric blasting-cap should be used with any gelatin. There is enormous potential energy in gelatin-dynamite, and in order to release it a No. 8 detonator is necessary.

Vanadium for Aeroplanes

Vanadium has been in great demand since the outbreak of the War for the steel parts of aeroplanes, submarines, and in armor plate for warships and armored motor-trucks. Light machine-guns and aerial artillery are almost wholly constructed of vanadium steel. In all cases where it is essential to reduce weight without sacrifice of strength, and especially where great resistance to shock is required, this alloy is employed. The growth of the vanadium industry has been phenomenal. In 1905 only 1000 tons of vanadium steel was produced. This was used for high-speed tool-steel. The present consumption of ferro-vanadium, which is used in the manufacture of the steel-alloy, is nearly 1000 tons per month, representing about 8000 tons of steel. The objections offered to the use of vanadium were essentially the same as those that now operate against molybdenum; it occurred in deposits that were not dependable. No assured supply was available, sufficient to sustain a growing market. The discovery of the famous vanadium sulphide (patronite) deposits in Peru in 1905 was the basis on which the industry grew. The mines are at an altitude of 16,300 ft., at Mina Ragna, 32 miles from Cerro de Pasco. The ore yields 19% vanadium, and an enormous tonnage has been developed. Its reduction is accomplished by an electric process, the details of which are not made public. Refining is done by other means, but the bulk of the world's vanadium is produced by methods largely perfected by D. Saklatwalla, chief metallurgist of the American Vanadium Co., at Bridgeville, Pennsylvania. This concern was developed from small beginnings about 25 years ago, when James Flannery, a Pittsburg undertaker, was compelled to take over the infant industry with the patents on which it was based, to cover a loan. This accident has made him a millionaire. At the beginning of the War the stock of the company was quoted at \$152 per share. Recently the controlling interest was acquired by a syndicate headed by J. L. Replogle, president of the Cambria Steel Co., at \$1000 per share.

Laurium and Preparedness

The silver mines of Laurium in Greece had been operated for many centuries with varying fortunes. In the time of Themistocles, in the fifth century B.C., the production of silver from these mines had fallen to nearly nothing. By his order the region was examined by a commission, on which the elder Xenophon was the leading spirit. As a result the mines were nationalized and a leasing system under rigid requirements as to continuous operation, was established. The State exercised close surveillance over the work, and facilitated the treatment of the ores and the refining of the output. This systematic effort led to such an enormous yield of silver that the profits excited the cupidity of the Athenians. A proposal was made by the chief men of the Athenian oligarchy to divide the proceeds among the

citizens. This was partly stimulated by political antagonisms, intended to weaken the authority of Themistocles and to add to the strength of his opponent, Aristides. Themistocles, however, realizing the peril of an invasion by the Persians, succeeded in overcoming the popular clamor and secured a vote in favor of utilizing the profits from the Laurium mines in the construction of a great navy for national defense. His foresight saved not only Athens but all Europe from the Asiatic foe. Xerxes bridged the Hellespont, crossed Thrace, Macedonia, and Thessaly, but was defeated at Salamis with the aid of the Athenian fleet in 480 B.C.

Electric Activity in Ore Deposits

It is well known that many chemical reactions are capable of developing measurable electric currents, and it should be expected that in places where chemical action is in progress in ore deposits today electric activity should be detectable. This has been shown to be the case by several experimenters. In Bulletin 548 of the U. S. Geological Survey, entitled 'Electric Activity in Ore Deposits,' Roger C. Wells records a series of measurements of electric potentials developed when various metallic minerals common in ore deposits are in contact with water or with solutions of various salts. Mr. Wells concludes that the character of the solutions has fully as great an influence on the electric activity developed as the nature of the metallic minerals, and that in general acid and oxidizing solutions give the highest potentials, and alkaline and reducing solutions the lowest. Economic geologists have long recognized that the solutions in the upper oxidized portions of many ore deposits are acid and oxidizing, while farther down they become neutral or alkaline. Whether such variations and the electric differences dependent upon them are sufficient to cause an appreciable electric current to flow from the upper part of an ore deposit to a lower part or vice versa is still an open question. Such action, if it exists, is of relatively minor importance in controlling ore deposition, the main factor being the actual movement of metal-bearing solutions from one place to another. Measurements of electric potential can, however, be easily made and may prove useful in indicating the direction and intensity of the chemical reactions of which they are one expression.

LABORATORY EQUIPMENT for testing rare-metal ores in quantities from 10 to 500 lb. has been installed at the technologic department of the Bureau of Mines at Golden, Colorado. The plant includes apparatus for making acid, alkaline, or saline leaches, as well as fusion-tests. A small wedge furnace and a tube-furnace affords facilities for roasting tests.

STETEFELDT, a metallurgist of wide experience, made the claim that amalgamation can be better accomplished in an arrastra than in an iron amalgamating-pan, the presence of the iron, he says, is detrimental to the best results in pan-amalgamation.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

PLATTEVILLE, WISCONSIN

SNOW AND BAD WEATHER HANDICAPS PRODUCTION.—HIGH PRICES MAINTAINED ALMOST TO THE END OF MARCH.—NEW MILLING PLANT GOING IN.

A disastrous sleet storm, which swept the entire Wisconsin zinc-bearing area, March 13, wrought considerable damage to the mining industry and associated interests. Roads were entirely obliterated, telegraph and telephone-lines were seriously injured, and power-lines were crippled. The tie-up on railroad lines extended over a period of several days and it was two weeks before the mining industry regained a normal condition. The storm could not have come at a more inopportune time. Prices for both zinc ore and lead ore, consistently high, had prevailed uniformly over a stretch of weeks and the more prominent zinc-producing groups were engaged in splendid profit-taking. Production was given a decided set-back and ore-deliveries were impeded to such an extent that whole districts failed to make their usual weekly reports. The incentive to 'make hay while the sun is shining' found operators working all over the field at maximum capacity until the break due to the elements came; then, many producers showed a decided curtailment in both output and delivery. As quickly as possible the damage was repaired but the showing expected under the favorable conditions prevailing at the beginning of the month failed to materialize and the complete returns for the field for the entire month were disappointing.

Prices for zinc ore uniformly high and constant all month found the base at the beginning of the month at \$90 per ton for premium-grade with the range down to \$85 on medium-grades. Refiners and producers shipping to smelter direct under contract agreements seemed to possess the advantage.

Aside from the market offered by the New Jersey Zinc Co. there was little or no open-market buying of low-grade ore in the field during the month. More and more there is coming into evidence a well-defined policy to circumvent this practice of the zinc-ore producing industry. The smelters represented in the field, and that are engaged in mining as well, have their local refineries and ship direct. Other large operating groups have their refineries and sell to the smelters under contract, while a few companies of prominence are selling mine-run product to smelters, and shipping the various grades of ore as they come from the jigs, also under flat-rate agreements. From this statement of facts it is evident that in a short time there will be little if any open-market selling. The competition which developed in the field recently between controlling smelter interests now is being reflected in a determined effort to conserve individual interests. New buying interests have to a large extent supplanted the older established outlets for Wisconsin zinc ore. The American Zinc Co. of Hillsboro, Illinois, not heretofore very active in the buying of high-grade ore, is fortified with the output of associated groups of mines in addition to the product secured through purchase. In matter of tonnage, thus obtained, it held strong, securing during March 79 cars—3119 tons. The Grasselli Chemical Co., of Cleveland, up to about a year ago regarded as no formidable contender for buying honors, through keen foresight, quietly, but aggressively, engineered a program of buying under contract agreement and how well this company succeeded is learned through last month's buying

when 69 cars went to the Cleveland concern for a total of 2546 tons. The plans of the New Jersey Zinc Co., far-sighted indeed, were adopted years back and include the operation of mines owned in fee by that syndicate as well as refining-plants on the ground, where local production is treated as well as the ores secured in open-market buying from the small independent producers. This combination, although expressed for the Wisconsin field only, explains why the New Jersey Zinc Co. has been able during the past few years to pay its famous dividends, and also why they will be continued. There was received at the reduction-plants of the Mineral Point Zinc Works, during March, 193 cars of mine-run ore aggregating 7378 tons, from which was extracted and shipped to smelter at DePue, 3461 tons of high-grade separator-blende. Other buyers of high-grade ore during March were the Edgar Zinc Co. which received 20 cars (753 tons) from the Oliver Mining Co. at Shullsburg; the Matthiesen & Hegeler Zinc Co. at La Salle, 19 cars (771 tons); the Illinois Zinc Co. at Peru, Illinois, 14 cars (556 tons); the American Metal Co., 7 cars (252 tons); the Eagle-Picher Lead Co., 5 cars (187 tons); and the Lan-Yon Zinc Co., 3 cars (132 tons). From all of the foregoing it is no difficult matter to infer which of the smelting interests is now in control in the Wisconsin field, and it is a fair criterion of what is taking place in other fields as well. The ancient and honorable peace, so long maintained between the leading smelter interests, it appears, has been destroyed and it is now a case of 'each for himself and devil take the hindmost.' That the conflict has inured to the advantage of the zinc-ore miner can be attested by the further fact that prices in the Wisconsin field for zinc ore for the month of March showed an unmistakable advantage over the quotations obtaining in the Missouri zinc districts, for the entire month. Had the weather remained fairly good, and had the field been spared the experience of the destructive sleet-storm above referred to, the month just closed would have been one of the most profitable in the history of the field. The conflict is by no means ended. Struggle for mastery must remain an interesting feature of the industry for some time to come.

Not until well toward the close of the month did there come any intimation of a break in prices and then a weakening metal-market precipitated a decline of \$5 per ton, the base receding to \$85 for premium-blende with the range down to \$80. Even at these figures advantage remained with the Wisconsin zinc-ore producers, since Joplin quotations for the same period had a wider latitude, the range running from \$70 to \$85.

Lead-ore producers in the Wisconsin field unloaded a small portion of their holdings in the early days of the month at the high prices then prevailing—about \$122.50 per ton. The metal-market showed no tendency to deteriorate, yet, in spite of this, a break came; the price dropping to \$115 per ton, base of 80% metal content. Production showed nothing of a surprising nature, but fair weather it is claimed by the experienced ones, will encourage miners to invade shallow diggings and rig-up open-wash places, when an increased output is expected.

While the demand for pyrite remained good and prices were fairly high no disposition was shown to market ore in quantity. The high prices for zinc ore, a scarcity of cars due to bad weather, and a determination to get all the zinc ore to market possible, were factors mainly responsible for the poor showing made in deliveries during March.

Producers of carbonate zinc ore, operating in the northern districts of the field, met serious drawbacks in the inclement

weather and correspondingly bad roads. The quotations offered were standard and steady, going from \$40 to \$60 per ton, base of 40% zinc content, but production was light and shipments restricted.

Much prospect work was carried through successfully during March and a number of new producers were ushered into active existence at several points in the field.

Deliveries of ore, for March, were reported by districts as follows:

Districts	Zinc, lb.	Lead, lb.	Pyrite, lb.
Benton	23,404,000	148,000
Mifflin	6,994,000	166,000
Linden	3,954,000	62,000	160,000
Cuba City	3,678,000	2,906,000
Galena	2,438,000	82,000
Hazel Green	2,422,000
Shullsburg	2,334,000	182,000
Platteville	2,178,000	132,000
Potosi	1,040,000	48,000
Highland	946,000
Montfort	176,000	60,000
Dodgeville	110,000
Mineral Point	56,000	1,126,000
Total	49,730,000	880,000	4,192,000

The gross recovery of crude concentrate aggregated 21,000 tons, net deliveries to smelter, including both refinery-ore shipped from separating-plants and mine-run direct, 12,333 tons. The Mineral Point Zinc Co. going with two reduction-plants, had an exceptionally good month after overhauling the plants, shipping nearly 7,000,000 lb. of top-grade blende to smelters at DePue.

Summarizing briefly, the more important developments in the field for March were as follows: In the Highland district, the New Jersey Zinc Co., after a determined search for water-supply for milling, lasting more than a year, was rewarded with an ample flow from a well 500 ft. deep, and a force of 60 men secured employment in a new mill finished a year ago. A demand for increased pay and shorter hours in the Montfort district resulted in a walkout and the discharge of the entire working-force at the O. P. David mine. Dodgeville welcomed a new producer to be known as the North Survey Mining Co. A contract for a 100-ton mill has been awarded to Charles Singer, the general manager for the Optimo & Linden Zinc Company. The M. & A. Mining Co. at Mifflin, after a successful run, has paid 40% in dividends. Double-shift became the order and heavy deposits were found in the mine-floor. The phenomenal showing made by the Block-House Zinc Co., at Platteville, resulted in the payment of \$60,000 in dividends, during the month on a capitalization of \$24,000, additional leaseholds were proved with drill prospecting, which will extend the life of the mine. Several new producers were brought to the shipping stage in the Cuba district. Benton made big gains in new developments and exerted itself in hard-road building. Five new power and mining-plants are to be built in this district. A branch of the Northwestern railway is being constructed to New Diggings, in the interest of the miners. The Mulcahy mine at Shullsburg, a new producer, showed up well and reaped rich dividends. The Birkbeck mine, a new find only recently developed and equipped in the Galena district, was abandoned. Potosi offered a new producer in the Tiffany mine, which settled down to a shipping basis, in keeping with the program

followed by the old regulars. The Galena-Joplin Separators operated for years with success suspended operations and the ores usually treated there will be diverted to the big Skinner separating-plant, at New Diggings.

LATOUCHE, ALASKA

CONSTRUCTION WORK ADVANCING RAPIDLY, AND PART OF THE NEW MILL IS IN OPERATION.—A WELL-APPOINTED CLUBHOUSE.

Rapid progress is being made in construction work in spite of the heavy snow-fall and the inclement weather generally. An addition to the power-house, an addition to the hospital, several new cottages, a hoist-house, and a compressor-building are under construction.

The addition to the power-house will accommodate two Diesel engines of 500 hp. each. At present 1000 hp. is supplied by steam-turbines.

The hoist-house will contain the engine that will hoist the ore from the haulage-drift that connects the mine with the mill; the ore will be dumped from the skips directly into bins in the new-crushing plant.

Two out of four of the proposed units of the new mill are in operation. The mill is equipped with Marcy ball-mills, Hardinge pebble-mills, flotation-machines, and Oliver filters. Each unit of the new mill can handle 500 tons per day. The new crushing-plant will be equipped with gyratories and Symond disc-crushers.

LATOUCHE, ALASKA

Three motors have arrived that will haul ore from the mine to the mill, horses being used for that purpose at present. The motors are 5-ton Westinghouse, and are equipped with storage-batteries.

About 350 men are employed here. E. T. Stannard is manager, and K. C. Stadtmueller is assistant manager.

The Latouche Club, with an initial membership of 45, has recently been formed and will formally open the new club-rooms with a big 'smoker' in the near future. The club-rooms contain bowling-alleys, pool and billiard-tables, a reading-room, and a library.

SUTTER CREEK, CALIFORNIA

KENNEDY MILL HANGING-UP STAMPS.—NEW ARGONAUT MILL NEARING COMPLETION.—CELEBRATION AT SUTTER CREEK.

Sinking is in progress at the Hardenburg mine, at Middle Bar, on the Mokelumne river, the intention being to put the shaft down an additional 300 ft. In this sinking, the vein will be crossed, the shaft being vertical, and levels will be run

below the intersection to prospect thoroughly the vein. W. J. Loring, whose company is reopening this mine, has spent the past week in Amador county.

At the Kennedy mine 40 stamps of the 100-stamp mill were hung up during the week, partly for repairs, but mostly as a result of a shortage of rock. The wages paid at the Kennedy mine are said to be lower than the rates prevailing at the other mines of the county and the company finds it more difficult to get miners. It is reported that the Argonaut Mining Co., whose property adjoins the Kennedy mine, raised the wage scale 25c. a day recently, so as to retain the full working force.

Twenty stamps will soon be dropping at the new mill of the Argonaut, which was recently erected on the hill west of the shaft. The 40 stamps now in operation at the old mill also will be removed shortly to the new mill, to work in conjunction with the heavier batteries with which the new plant is equipped. During the process of moving, the intention is to keep 40 stamps in operation, only 20 of the old stamps being moved at a time.

W. E. Darrow's new plant for handling the tailing from this up-to-date mill is in course of construction between the mill and the large Eastwood dam and will be completed by the time the mill begins crushing.

The Crown Point quartz claim, near Drytown, has been bonded by Mrs. M. E. Fontenrose, of Jackson, to G. C. Dickerson for a consideration of \$7000, of which \$5000 is payable on or before October 1, 1917, and \$2000 on or before April 1, 1918.

Sutter Creek already presents a gala appearance in preparation for the Mother Lode carnival to be held here on Saturday, April 14. Flags, bunting, evergreen, and incandescent-lamps have transformed the appearance of the principal streets. An immense arch has been erected across Main street, under which will march the parade with characteristic features commemorative of pioneer days, and illustrating the progress since made in the mining industry. The forenoon's exercises, consisting of music, speeches, a drilling-contest, and first-aid work, will be held at the old Eureka ground. Three brass-bands have been engaged for the day in addition to the dance-orchestras. In the afternoon will be held a track-meet at the high-school, in which various schools will compete; also a baseball-game between the star teams of the county. Several dances will be given, one at Levaggi's hall, during the entire afternoon and evening, and one at each of the local garages during the evening. A tug-of-war is scheduled for the evening on Main street, as well as a band-concert and a confetti-carnival. The carnival has been arranged as a fitting expression of the satisfaction of the people in the renewed mining prosperity, and particularly in honor of the re-opening of such old producers as the Old Eureka and the Plymouth Consolidated mines, and the extension of mining operations at several other important mines.

AFRICA

The management of the Ashanti Goldfields Corporation (Ltd.), reports by cable that the returns for February were as follows: 8829 short tons was crushed, yielding 9508 oz. of fine gold, having an estimated value of £40,322.

The results for January were:

Value of output	£40,280
Working costs in West Africa and general expenses in London	17,180
	£23,100
Government royalty, 5% on output.....	£2,014
Total cost of mines development.....	4,076
Depreciation on plant, machinery, etc.....	1,820
	£ 7,910
Estimated profit	£15,190

ELY, NEVADA

LARGE SCALE OPERATIONS AT THE RUTH MINE.—ARRANGEMENTS TO FACILITATE AND INCREASE OUTPUT.—THE LINCOLN HIGHWAY.

The Nevada Consolidated Co. is running full blast, putting through the mill, close to 13,000 tons daily; of this, over 3000 tons is coming from the underground mining operations in the Ruth mine.

The Star Pointer shaft (working shaft of the Ruth) has been deepened 200 ft. and driving is in progress at this level at both ends, 2100 ft. between the faces, to get in shape for extensive mining on this level, also to increase the tonnage from the Ruth. A new electric-hoist, of 5000 tons capacity, has been ordered, also more electric-locomotives for underground transportation. The company expects to handle 5000 tons daily from the Ruth, in the near future. At the concentrator at McGill construction work on the new crushing-plant is being crowded; owing to delays in receiving the machinery, it will be two months before this can be put in operation. It will increase the capacity 25 to 35%. By moving the assembling-yards, which are now near the steam-shovel pits, down to the flat near Keystone, and with dinky-engines delivering the cars there and taking the empties back, it is said that the present equipment of the Nevada Northern railroad, by adding automatic-dumping ore-cars to its equipment, will be able to handle the increased tonnage. Up to the present the facilities for ore transportation between mines and smelter have not been adequate and the changes mentioned have been contemplated for some time past.

The Consolidated Copper Mines Co. (old Giroux) mill 500-ton unit is running through 600 tons daily, and it is said that the results are satisfactory; this ore comes from the underground mining at the Morris shaft. The additional unit of 500 tons is being pushed to completion as fast as possible; but here also there are delays in the delivery of necessary materials. Captain Hogan, who was in charge of sinking what is known as the New Giroux shaft (on the Alpha side of the Giroux property) is back, in charge of operations on this shaft. From the tenth level he has been repairing and re-timbering the level out into the Alpha orebody. He has already extracted a few cars of ore. This ore is all carbonate in the oxidized zone; it is of good grade, and will stand shipment to the Salt Lake smelters at this time, owing to the high price of copper. There was a considerable tonnage blocked out here before the Alpha shaft was lost. The water-level in the New Giroux shaft for a long time has stood a little below the tenth level. Water is obtained by pumping from this shaft for milling purposes; but it has only lowered the water in the shaft about 35 ft. The electrical pumping-plant on the twelfth level has been drowned for the past two years. It is said that extensive drilling-operations will be commenced on the Giroux in the near future. It is generally understood that this property now is controlled by Humphreys, Merritt, and Burgess, who, it is said, have recently financed the operations. Lessees throughout the county are not yet shipping much ore, owing to the condition of the roads.

The county commissioners of White Pine county are advertising for bids to change the road up Robinson canyon between Ely and the mines. The canyon is narrow and it is occupied by both the railroad and the wagon-road; it is also a part of the Lincoln highway across the continent that eventually will be made a military road. This road is the most traveled of any road in the county. There are 13 grade-crossings, some of them dangerous. The proposed change will cost \$20,000, but as the Nevada Consolidated Co. pays 84% of the taxes of the county, and are anxious for it, the Nevada railroad will move its tracks without cost to conform to the changes. This much needed improvement will be made now, while the county is prosperous. The change will eliminate all but three of the crossings.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

(Special Correspondence.)—Robbers recently stole a \$20,000 gold brick from the Chichagoff mine, on Chichagoff island. Suspected men were arrested and have been brought to Juneau for trial.—The change-house at the Treadwell shaft of the Alaska Treadwell Gold Mining Co., was destroyed by fire on March 13.—The first unit of the Alaska Juneau 8000-ton mill was placed in operation on April 1. The start was made without a hitch. The remainder of the mill will be placed in operation as soon as completed.—D. McLennan and Colin Brown, construction foremen, who have been associated with the Bradley, Bruff & Labarthe Co. in building the Alaska Juneau mill, will leave for Burma, upon completion of their work here.

Juneau, April 4.

The Jualin mine, at Jualin, is producing \$20,000 monthly. C. G. Titus is superintendent.

The March output of the Alaska Gold company was 217,700 tons, that averaged \$1.09 per ton, 26 cents lower than the average during February.

General manager Thane explains that the management last month decided to treat the large amount of low-grade ore that was broken in the stopes. If the company decides to clean up the rest of this low-grade ore, the probabilities are that the assay value for the next month or two will not vary much from the March average. There is, however, considerable ore of better grade that will later become available for milling. When this reaches the mill the assay value should show a substantial increase.

The mill during March was operated on a 7000-ton daily average basis, or 1000 tons in excess of the original estimate of the company. Its actual capacity is nearly double that amount, or between 12,000 and 15,000 tons daily. The tailing losses in February were but 18.7c. per ton, the lowest in any month since the company started the issuance of monthly production figures. Since April last, when the ore assayed but 94c. per ton, the tailing losses invariably have increased a cent or two per ton.

ARIZONA

COCHISE COUNTY

(Special Correspondence.)—An electrically driven pump has been placed on the 1800-ft. level of Junction shaft of the Calumet & Arizona Mining Co. to lift 1000 gal. of water per minute. The Junction shaft, when lined with concrete throughout its five compartments, from top to bottom, three years ago, was the deepest mine work of that kind attempted up to the time. The pump will be run by power from the company's smelter at Douglas, conveyed over a line just completed. In addition to the production of copper ore in this district, zinc-lead shipments are made to Kansas City, manganese is shipped to Chicago, and sulphuric acid is made from local sulphides, and goes principally to the New Cornelia Copper Co. at Ajo, where it is used in the recovery of the copper from carbonate ores. In addition the district is shipping fluxing-ores, mainly sulphides, to Sascos, Globe, and El Paso smelters.

Douglas, April 11.

GILA COUNTY

The Globe Commercial Copper Co. is shipping three cars of manganese ore weekly from its mines near Globe. A large body of 40% ore is said to have been opened. The ore goes to Temple, Pennsylvania.

MARICOPA COUNTY

(Special Correspondence.)—The Superstition mining district, known in the early days as Goldfield, has awakened after a long period of idleness. The Goldfield Development Co., an organization of Salt River Valley business men, has sent to its property a 60-hp. oil-engine and air-compressor. Other equipment will be installed in the near future. The development plan has not been fully decided but will probably include a vertical two-compartment shaft, situated in the centre of an intrusive granite mass in which are many encouraging gold-bearing outcrops. The geological structure is complex, showing evidence of several periods of volcanic activity.

Ben Blackburn and associates are starting a new shaft upon their group of claims in another part of the district. They will continue sinking until water-level is reached. There are several other projects under way but these are as yet in the prospect stage, though promising.

Mesa, April 10.

MOHAVE COUNTY

(Special Correspondence.)—The United Eastern Mining Co. has purchased the Big Jim and Monarch claims from the Big Jim Gold Mining Co., paying therefor in treasury-stock at the rate of one share of United Eastern for six shares of Big Jim. The Big Jim has outstanding 750,000 shares of stock, requiring the payment of 158,333 shares of United Eastern. At the market, \$4.80 the day of sale, this stock was worth \$760,000, without considering the enhanced value through the acquisition of the Big Jim mine. United Eastern stock received in the deal will be delivered pro rata to Big Jim stockholders. A new company, the Big Jim Consolidated, has been organized to take over the Blue Bird mine, owned by the Big Jim Gold Mining Co., and stock in the new company will be issued to stockholders in the new company. The Blue Bird joins the United Eastern end-line on the north-west. It has a full equipment of machinery and a two-compartment shaft down 240 ft. The Big Jim Consolidated starts with a treasury fund of \$20,000. United Eastern production in March was the highest since the mill started, when \$150,091 in bullion was produced from 6584 tons of ore averaging \$23 per ton. This is an increase of 1201 tons and \$29,915 over February. Production since the mill started January 4, was \$353,356 from 15,767 tons of ore. It is reported that the company will go on a monthly-dividend basis in July. Flotation-tests are being conducted on ores from the Gold Road mine at the concentrator of the United States Smelting & Refining Co., at Needles, California. A large tonnage of ore is being developed in the far east workings on the 100, 500, and 800-ft. levels. The mine is owned by the U. S. company and has a 300-ton cyanide mill. Sinking has been resumed in a winze from the 530-ft. level of the Gold Ore mine. The vein is five feet wide and shows free gold. The ore averaged \$40 per ton for 33 ft., the depth of the winze. This company also is experimenting with flotation. It is near the Gold Road mine, on a parallel vein.

Oatman, April 11.

Recent development work in one of the upper adits of the McCracken mine in Cedar district, resulted in finding 2 ft. of high-grade lead-silver ore, and 6 ft. of concentrating ore, carrying 10 to 15% lead with silver. Work is also progressing on the lower level, and the rock broken, although low-grade, is promising and better ore is expected daily. In its early history the McCracken produced a great deal of rich ore that was shipped at high cost, but which returned large profit.

PIMA COUNTY

(Special Correspondence.)—John D. Cowan, of Salt Lake City, Utah, and associates, who own the Tucson-Arizona mines, situated 42 miles west of Tucson, Arizona, will expend about \$100,000 in the purchase of machinery and equipment for the development of the property.

The New York-McAneney Consolidated Mines Co., of which Mitt Quenner, of Los Angeles, California, is general manager, will install concentrating-machines and other equipment for operating dry placers at Greaterville, Arizona.

Tucson, April 12.

SANTA CRUZ COUNTY

(Special Correspondence.)—The Lower California Mining & Reduction Co. will erect a reverberatory-furnace as an addition to the concentrating-mill which it is now building at its mines three miles north of Nogales.

Nogales, April 11.

The shaft being sunk at the mine of the Arizona Consolidated Copper Co. at Mowry, reached the water-level about the first of the month and is still going down. The water is being bailed for the time being, but an increase in the inflow is anticipated and a pump will soon be required. Fred J. Miller is superintendent.

CALIFORNIA

The report of the State oil inspector for the week ended April 7, shows 16 new wells, making a total of 303 since the first of the year; 21 test of water shut-off; 15 deepening or re-drilling jobs, and 5 abandonments.

AMADOR COUNTY

It is reported that some recent development in the Oneida mine, owned by the South Eureka Mining Co., has been very satisfactory to the management. A large vein of good ore is said to have been developed in the lowest level of the Oneida, and the mill is running at full capacity. So abundant is the ore that plans are under consideration for the enlargement of the milling facilities.

Arrangements have been made for the treatment of a large tonnage of tailing from the Argonaut mill, near Jackson. W. E. Darrow and his associates will work the tailing by the Darrow method that for years has been successfully in use at the Bunker Hill mine near Amador City. Work on the Darrow plant has commenced.

BUTTE COUNTY

Frank Alexander, of San Francisco, has taken an option on 40 acres of land near Pentz grade, 12 miles from Oroville, for the purpose of working deposits of chrome. Work will begin at once.

INYO COUNTY

(Special Correspondence.)—The towns of Keeler and Darwin have experienced a revival of mining activity that promises to be permanent. The Cerro Gordo mine, 7 miles north-east of Keeler, about five years ago was not doing very well. Louis D. Gordon took a lease on it, and after expending thousands of dollars in overhauling the aerial-tramway, operated the mine profitably. When his lease expired October 1, 1915, the owners declined to renew it, but employed him as superintendent, and it continues to yield a handsome profit on its operations. Meanwhile, it is said, Mr. Gordon has secured a controlling interest in the property. The Darwin Development Co., an Eastern concern, also is making good at Darwin, about 20 miles south of Keeler. This company secured the Lane and Lucky Jim mines, and after putting in one unit of an oil-flotation plant and proving its efficiency in concentrating the silver-lead ore of that district, they have purchased the old-time Defiance mine, and the water-right at Coso, 8 miles south-west from Darwin, which furnishes the water-supply for the town of Darwin and the mines in the vicinity.

They intend to add more units to their plant and bring the mine again into the list of profitable producers.

Keeler, April 12.

MARIPOSA COUNTY

The Mount Gaines mine, 6 miles east of Hornitos, is to be re-opened after a long idleness. It is reported that \$50,000 will be spent in additional machinery, improvements, and development. The work is to be undertaken by Los Angeles people. W. J. McCray is manager. Electric hoists are to be installed. In the early days of the mine's career, steam-power was used, but later electricity was substituted, and the hoisting and drilling were done from the same unit—the compressor. By having separate units for the various branches of work, the mine is expected to be operated with greater economy. There are 12 men working at the property at present.

The Ruth Pierce mine near Hornitos is employing 25 men, who are working in three shifts. The mill is running and the output is satisfactory. James McMahon is manager.

NEVADA COUNTY

At the Allison Ranch mine, a few miles down the creek from Grass Valley, two large electrically driven pumps have been installed and the unwatering of the mine that has been idle for 17 years will soon be commenced. In its early history the Allison Ranch was one of the famously rich mines of this county, but the heavy influx of water resulted in closing it. When last in operation, about 1900, it was stated that the influx of water was 675 cu. ft. per minute. It is expected, however, that the modern pumps will handle the water without difficulty.

PLUMAS COUNTY

A discovery of a small vein of rich gold quartz has been made in the mine of the Plumas Basin Mines Co. The mine is in Granite basin. The new strike is on the 300-ft. level.

RIVERSIDE COUNTY

(Special Correspondence.)—Neil MacDonald, of New York, who owns a gold mine near Hemet, in the San Jacinto mountains, has ordered a No. 2 Denver quartz-mill, and other machinery equipment of the Denver Quartz Mill & Crusher Co. The ore is free-milling and will be treated by amalgamation. A. H. Cooper is superintendent.

Hemet, April 7.

SISKIYOU COUNTY

(Special Correspondence.)—The Dewey mine, also known as the Squaw Creek mine, is again in operation after an idleness of eight years. The mill is crushing 25 tons daily. Notwithstanding the fact that the workings were badly caved the new superintendent, Algernon Del Mar, has managed to pay expenses by drawing on ore already broken in the stopes. The primary cause for the shutting-down of the mine was inability to get fuel at a cost that was not prohibitive. The mine is now equipped with an electric-power line 8 miles long. The line is constructed of No. 6 galvanized-iron telephone-wire and carries 10,000 volts. It is intended to utilize 200 hp. The galvanized-iron wire, although not nearly so good a conductor of electricity as copper, is so much cheaper that it was considered good business to install it. The 8 miles of line did not cost over \$5000 completed. The current is transformed to 440 volts, with separate motors for rock-breakers, stamps, and concentrators. It is intended later to re-grind the tailing and treat by flotation that which escapes from the Wilfleys.

Gazelle, April 5.

TRINITY COUNTY

The Schlomberg hydraulic mine on Coffee creek, owned by Stewart & Phillips, is to be operated this season. About \$15,000 has been spent in equipment. The work will be in charge of Henry Carter.

TULARE COUNTY

(Special Correspondence.)—The largest rotary-kiln in use

in the world for the calcining of magnesite is being built by the Porterville Magnesite Co. at its plant three miles north-east of Porterville. It will be ready for operating the latter part of the month. The kiln is 125 ft. long, 7 ft. in diameter, and weighs between 50 and 60 tons. Five railroad flat-cars were necessary for its transportation from Allentown, Pennsylvania. It was originally intended for the burning of cement and was installed for that purpose at Santa Cruz, California, but never was used. It will be run by a 50-hp. electric-motor and will operate under a temperature of 2000°F., but as there is no other kiln of such great size in operation, its capacity can only be surmized; however, it is thought it can produce from 60 to 70 tons of calcined ore per day. The Porterville Magnesite Co. is the largest operating company in this district. They have under lease 680 acres containing extensive deposits of magnesite of good quality. More than 300 men are employed, about 50 of whom work at the calcining-plant where a 50-ft. kiln has been in operation for some time, and which will continue to operate. The officers of this company are Walker W. Kamm, president; R. S. Edwards, vice-president; Philip S. Kamm, secretary-treasurer, all of San Francisco. F. F. Parker is local superintendent.

Porterville, April 12.

YUBA COUNTY

(Special Correspondence.)—With an option to purchase 1155 acres of the Ayer's estate across Bear river, 10 miles east of Lincoln, William B. Swears, of San Francisco, has secured what promises to be a valuable copper property.

Mr. Swears has known this property for many years, and 35 years ago sent samples to Denver for assays. At that time he was after the gold value in the ore, as the copper was then of little value. Many years ago the Ayer's estate, of Boston, bought 35,000 acres of land in the foothills of Yuba, Placer, and Nevada counties, and Mr. Swears on December 14, last, tied up the 1155 acres adjoining the Dairy Farm mine, owned by the Guggenheims. The property is two miles north of the Dairy Farm and one-half mile from the Guggenheim railroad, which carries the ore of the Dairy Farm mine to Sheridan. It is 10 miles by a good county road to Lincoln. The power line of the Pacific Gas & Electric Co. crosses the property and within 400 ft. of the main shafts. The principal showing of ore is in a shaft sunk close to Rock creek, but within a radius of one-half mile, nine shafts have been sunk or adits run, and in each the same clean massive sulphide ore has been found at water-level. Numerous assays of samples taken by engineers have returned from 5 to 9% copper, and \$8 in gold and silver per ton.

The ore in place runs about 6 cu. ft. to the ton. Through the property run four dikes, that in which Rock Creek shaft is sunk, is a mineralized zone 5000 ft. long and 100 ft. wide.

Six hundred feet to the left of Rock creek is a gossan, 3000 ft. long and 75 to 100 ft. wide, carrying good value in gold. Extensive development has been commenced on the property, including a new shaft on the hill above the creek. Several of the old shafts are being re-opened, and a large force of men will be kept busy. Machinery and lumber have been ordered and houses are being built for the employees. Within 30 days shipments of ore to a smelter in Nevada will begin.

Lincoln, April 11.

COLORADO

OURAY COUNTY

The Mountain Top Mining Co. has recently completed an innovation in mining practice—a stamp-mill of 50 tons daily capacity, erected underground, 1000 ft. in from the portal of the adit, and 400 ft. vertically beneath the surface. Each department of the mill occupies a separate chamber cut in the solid rock, and these are connected by inclined raises. The Ouray *Plaindealer* thus described this unique installation: The mill has a capacity of 50 tons each 24 hours, and the equipment is as follows: Ore from the mine-cars is dumped into an auto-

matic-dumping skip, is then hoisted 100 ft. and dumped into an ore-bin at the top of the mill, from which it passes over a grizzly to a rock-crusher, thence to the crushed-ore bin; subsequent treatment is by a ball-mill, worked in closed circuit with a Dorr simplex-classifier; roughing-tables, flotation, followed by flotation of both tailing and flotation-froth. Each of the several units is operated by a separate drive, there being altogether thirteen different motors used for that purpose. One advantage, at least, of this subterranean mill is that it will be absolutely free from disaster from snow-slides, no fire insurance is necessary, the temperature is uniform, and no fires are required.

The Gold Crown mill, just north of the town of Ouray, has been finished and has been making its trial run. The ore consists of quartz, calcium carbonate, and magnesian silicates through which is disseminated auriferous pyrite and chalcoppyrite. The mill is modern and includes flotation-apparatus, partly of original design.

SAN JUAN COUNTY

The Sunnyside mine, near Silverton, has been consolidated with the Gold Prince mine and will hereafter be known as the Sunnyside Mining & Milling Co. A 500-ton mill is to be built as soon as possible. The property is on the Mastodon vein. The Gold Prince mine was equipped with a mill, built at Animas Forks, which was connected with the mine by an aerial tramway over 12,000 ft. long. The mill or the process employed was not adapted to the ore and the property was closed-down. The new mill will be built at Eureka. The Sunnyside is said to have large bodies of zinc ore developed. The ore also carries gold and silver. Considerable ore was shipped last year. J. T. Terry is manager of the new consolidation.

MICHIGAN

HOUGHTON COUNTY

The Calumet & Hecla mine is now hoisting and crushing about 10,660 tons of ore daily. It is expected to increase this tonnage when better weather prevails. The Osceola is producing to the full capacity of its milling facilities—4700 tons of ore daily. The output of the Mass mine is 1000 tons of ore per day.

NEVADA

ELKO COUNTY

The recent prosperity of Jarbidge has resulted in a sudden and unexpected increase in the population of that camp, in consequence of which there is a shortage of food there. Although the merchants last fall laid in what was deemed a sufficient supply for the winter, they did not count on the favorable development of the district inducing what amounts to a stampede to the place. The strangers have drawn heavily on the food-supply. The high cost of living at Jarbidge is influenced by such incidental items as: Potatoes at \$20 sack; sugar at \$30 per 100 lb.; and hay at \$100 per ton. The camp is at present practically snowbound and inaccessible, but the energetic miners and merchants will find a way to meet the actual necessities of the people.

NYE COUNTY

A discovery of rich gold ore in the granite in Shoshone canyon, two miles east of Round Mountain, is announced. It is near the tungsten mines discovered there a year ago. The gold is found in a small vein that has been opened for 20 ft. or more.

STOREY COUNTY

(Special Correspondence.)—Not in more than 30 years has mining development been so active on the Comstock Lode as now. Not only is there greater activity, but indications are favorable to success elsewhere than in the stock-market. For years—ever since the workings were unwatered below the

Sutro-tunnel level, in 1899—several of the north-end mines have been operated with some success, particularly the Mexican and Ophir, and more recently the Union and Sierra Nevada, but now a new development on the 2700-ft. level of the Consolidated Virginia promises to start a general revival throughout the entire length of the great Lode. The Combination shaft, that was sunk jointly by the Chollar, Potosi, and Hale & Norcross mining companies, to a depth of 3300 ft. is to be the scene of renewed activity. This is a great vertical shaft, and has been utilized for years as a pumping and ventilating shaft. As it was an up-cast the heated air, laden with watery vapors, ascended the shaft and condensed on reaching the cool air nearer the surface and fell constantly, drenching the timbers and preserving them from the decay which would have been inevitable had it been a dry down-cast shaft. New electrical equipment is to be installed under the direction of Whitman Symmes, manager for the Middle Mines Association. Through the operations at the Combination shaft, the mines between Virginia City and Gold Hill will be unwatered, as the north-end mines have been through the C. & C. shaft of the Consolidated Virginia.

In the latter mine the south drift on the 2700-ft. level has advanced about 80 ft. in solid ore of fair average grade and stoping has commenced. Raises will be cut in the orebody and the drift extended southward, and cross-cuts run to determine the extent and value of the mineralization, for at present it is impossible to form any conjecture of the size and value that this new discovery may develop. The usual Comstock practice of square-setting has commenced in the stope recently started, and developments will be watched with more than ordinary interest.

Virginia City, April 12.

NEW MEXICO

(Special Correspondence.)—The Buckeye Copper Co. will install new machinery and equipment at its mine near Magdalena. It is owned by William Kemp of Magdalena and Trost Bros., of El Paso, Texas.

Magdalena, April 12.

GRANT COUNTY

(Special Correspondence.)—The Jumbo Mining Co., which was recently incorporated at Deming with a capital stock of \$250,000, will install machinery and equipment for the development of its property. C. J. Kelly, of Deming, is a stockholder.

The Alhambra Silver Mining Co. is being organized by C. C. Royal, of Silver City, for the purpose of taking over the old Alhambra mine in the Alhambra-Black Hawk camp; it is several miles north-west of Tyrone. A cyanide-mill will be installed.

The Pyramid Leasing & Mining Co., which has been incorporated at Lordsburg with a capital of \$50,000, will install machinery and equipment for development and operation. William M. Fink of El Paso, Texas, is a stockholder.

Deming, April 11.

OREGON

JACKSON COUNTY

(Special Correspondence.)—The Nellie Wright mine is on the south slope of Blackwell hill two miles east of Gold Hill, and consists of 40 acres of land. It is situated within half a mile of the Pacific highway. It was recently sold to Salt Lake City people, who are now operating the mine under the management of R. M. Wilson. The former owners were Canadians with P. C. Donovan, of Winnipeg, as manager. The consideration was about \$25,000, with a substantial cash payment. This mine is equipped with a 25-ton Beers mill, plates, and a Johnson concentrator. The mill is situated at the main shaft. The shaft is equipped with a modern hoist, and all the machinery is operated by electric power. The new owners are installing compressors and drill-machinery. There are two

shafts 130 ft. apart and 50 and 60 ft. deep, respectively. These are connected by a drift which extends 120 ft. beyond the shafts. The ore is chiefly quartz with some pyrite, chalcopyrite, and a dark sulphide that probably is galena. The vein strikes N 75° W., and dips 87° N.; it varies in thickness from 2 to 5 ft. The country rock is the Siskiyou tonalite, which is here traversed by a dike of andesite. The vein cuts both the tonalite and the dike.

This vein was discovered by James F. Davis, a veteran miner of this district, in 1902. The discovery was made on the land of a homesteader who had acquired a patent for the land in the early nineties. Soon after the discovery Davis acquired the property and sold the prospect to Portland parties. The first real development was made in 1904, by Wright, a mining man from Denver, who operated under a lease and option from the Portland people. Financial troubles soon overtook Wright, and he was compelled to abandon his venture before he was able to make a mine out of the prospect. He named it for his daughter, the Nellie Wright mine.

In 1911 the ownership of the property passed to the Canadians, who in 1913 equipped the mine with machinery, developed the vein by sinking and driving as described. In the meantime they operated the machinery for several months, testing the value of the mine. The next year the War came on and the property has been idle until now.

Several thousand tons of ore has been treated with the present machinery. The ore is free-milling, averaging \$10 per ton in free gold, and it also produces some concentrate, carrying gold. There is several thousand tons of ore in the block above the 250-ft. drift. The owners are preparing to operate the mine to its full capacity. They will sink 50 ft. deeper in the main shaft and run a new level.

Gold Hill, April 10.

WASHINGTON

STEVENS COUNTY

The United Copper mine, in Chewelah district, has attained a depth of 100 ft. and will increase production, both in quantity and quality of ore. The company is considering sinking to 1500 ft. and developing the orebody on four new levels. On the 1100-ft. level a drift has been started south, in which direction the rich shoot appears to be widening, being 4 ft. wide, where it was encountered, 22 inches of it containing 21.24% copper and 134.5 oz. silver, with a combined gross value of \$222.94 per ton. The full width of the shoot has an average value of \$67.97 per ton, and the shoot has an estimated length of 1300 ft. The ore blocked out in the mine is estimated at 300,000 tons with an average value of about \$10 per ton. A check for \$8283 was received from February shipments of ore and concentrate, bringing the month's receipts up to \$31,106, which, with a carload at the smelter not yet settled for, is expected to raise the receipts from February shipments to \$56,000. The concentrating-mill is running on low-grade ore and is expected to handle about 150 tons per day. The mine has approximately 35,000 ft. of openings, and, with pay-ore from the surface to the 1100-ft. level, has yielded about \$1,000,000 to date.

A carload of ore is awaiting a better condition of the roads from the Iroquois mine, Electric Point district. An adit to intercept the orebody at greater depth is in about 200 ft. with 100 ft. farther to run.

The Providence Mining & Milling Co. has cut a body of \$10 silver-lead ore, 27 ft. wide, from the bottom of a 50-ft. shaft, in a new prospect five miles north-west of Northport. Ore accumulating on the dump will be shipped to the smelter as soon as a wagon-road can be built.

A body of \$10 silver-lead ore, which can be concentrated 12 to 1, has been cross-cut in an adit 60 ft. from the portal, by the Mineral Belt Mining Co., three miles north-west of Northport. An adit to cut the vein at a depth of 300 ft. is in 200 ft., with 250 ft. to run. The vein is 2 ft. wide.

In the F. H. & C. mine, in Orient district, a vein 14 ft. wide has been intersected in a cross-cut driven 18 ft. from a 30-ft. shaft. Five feet of this ore assays from \$25 to \$150 per ton in gold and silver. Machinery installed is a hoist, good for a depth of 500 ft., and a two-drill compressor. The shaft will be sunk to a depth of 100 ft. and a level opened.

CANADA

BRITISH COLUMBIA

On March 31, the Consolidated Mining & Smelting Co. of Canada, Ltd., closed its mines in Rossland indefinitely. This action is said to have been taken for two reasons, first, on account of the uncertainty of an adequate supply of coke being obtainable from the Crowsnest district of south-east Kootenay, where the agreement between the coal mine operators and the United States Workers of America, which controls the miners and other employees of the coal-mining companies operating in that district has expired, and next, in view of an unexpected concerted demand by the metalliferous miners throughout the district for an advance in wages of fifty cents per day. Practically 500 or 600 men are affected by the company's action.

In connection with the uncertainty of the supply of coke being sufficient for the continued operation of the company's copper blast-furnaces at Trail, it is manifest that no dependence can at present be placed on the Crowsnest district for the output of coke being maintained, for news was received in Victoria recently to the effect that at the Crow's Nest Pass Coal Co.'s colliery at Michel the miners had stopped work, while similar action may be taken any day by those employed at the company's Coal Creek colliery. With the Michel mines and coke ovens idle, the outlook for coke being obtained for the Trail blast-furnaces was less favorable; if the ovens at Fernie shall also be allowed to become inoperative, which must be the result if the miners shall suspend work at Coal Creek, whence comes the slack for burning into coke at Fernie, then the chances for obtaining coke for Trail, Grand Forks, Greenwood, and Northport smelting works will be small indeed.

The official preliminary estimate of the copper production of British Columbia, in 1916, is given as follows:

	Pounds
Northern Coast (Skeena) division	26,056,005
Southern Coast district	18,853,916
Boundary district	16,618,284
Trail Creek (Rossland) division	4,081,500
Omineca division (chiefly Rocher Deboile mountain)	1,262,730
All other districts	884,640

Estimated total 67,757,075

In his comments the Provincial Mineralogist stated that copper-mining is now the most important form of mining in the Province, and in 1916 the value of the copper mined (\$18,429,924) exceeded the total value of all other metalliferous minerals, and also exceeded the combined value of the coal and coke production for the year.

KOREA

The Seoul Mining Co., operating the Suan Concession in Whanghal province, Korea, reports the following results for the month of March: Total recovery, \$156,760. The Tul Mi Chung mill averaged 460 tons daily. Underground developments at Tul Mi Chung continue to improve. At the Tong Ahm, a prospect, values are improving.

NICARAGUA

The new mill of the Eden Mining Co. in the Pispis district is nearing completion. Tube-mills form a part of the equipment. It is expected that the company will soon be able to start the mill and enter on a long period of prosperity. Numerous American engineers have examined the mines of the district, one of the latest being J. E. Spurr.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

ROBERT STICHT is at Pasadena.

F. W. OLDFIELD is in New York.

ROBERT A. KINZIE is at Bishop, Nevada.

D. M. RIORDAN has gone to Hanover, New Mexico.

HENRY BRINGS is in San Francisco from El Paso.

BEN S. REVETT has returned to San Francisco from Idaho.

E. E. CARPENTER of Nevada has returned from Nicaragua.

CHARLES E. BRUFF, of Bradley, Bruff & Labarthe, is at Juneau.

JACOB W. YOUNG, now at Oakland, sails for Valdez, Alaska, on May 8.

H. R. NORSWORTHY has returned to San Francisco from the Belgian Congo.

ERNEST LEVY has re-opened his office at 1024 Old National Bank Bdg., Spokane.

J. E. SPURR has returned to Philadelphia from the Eden mines in north-east Nicaragua.

ROSS B. HOFFMANN returned to Oakland last week from Siberia and is now in New York.

H. J. SHEAFE has been appointed superintendent of the Globe mine, in Trinity county, California.

RUSS M. HESS has resigned the superintendency of the Stoddard Mines Co. of Arizona and is in New York.

W. A. POMEROY and W. R. HAMILTON have formed a partnership with offices in the Hobart building, San Francisco.

EDMUND JUESSEN has been appointed general manager for the New Almaden Company, at New Almaden, California.

W. H. LANDERS has resigned as manager for the New Almaden Co. and will offer his services to the Government.

CARLILE P. WINSLOW has succeeded HOWARD F. WEISS as director of the Federal Forest Products Laboratory, at Madison, Wisconsin.

JAMES W. ABBOTT, who has been at St. Luke's hospital, San Francisco, for several weeks, has recovered sufficiently to go to Buffalo, New York.

Obituary

WILLIAM J. NETTLE, SR., who for years has been superintendent of the Argonaut mine at Jackson, California, died at his home at Jackson, April 11, from miners' phthisis. Mr. Nettle was well known to the miners of the Mother Lode, and was one of the capable men who came up from the ranks of the workers.

RESEARCH FELLOWSHIPS are offered by the College of Mines of the University of Washington in co-operation with the U. S. Bureau of Mines. The value of each fellowship is \$720 per year, beginning July 1, 1917. Fellowship holders will register as graduate students, becoming candidates for the degree of Master of Science in mining engineering or metallurgy, unless an equivalent degree has previously been earned. These fellowships are open to graduates of universities and technical schools throughout the country. Five scholarships are offered, namely, (1) electro-metallurgical processes, (2) beneficiation of coal and non-metalliferous minerals, (3) clay industry and ceramics, (4) general problems affecting the ores and the mining industry of the State, and (5) the development of metallurgical industries. Applicants must send to the Dean of the College of Mines, Seattle, Washington, before May 15, a copy of their collegiate record issued by the registrar of the institution from which they graduated.

THE METAL MARKET

METAL PRICES

San Francisco, April 17

Antimony, cents per pound	24
Electrolytic copper, cents per pound	37
Pig lead, cents per pound	9.25-10.25
Platinum, soft and hard metal, per ounce	\$105-111
Quicksilver, per flask of 75 lb.	\$115
Spelter, cents per pound	12
Tin, cents per pound	50
Zinc-dust, cents per pound	19-20

ORE PRICES

San Francisco, April 17

Antimony, 50% metal, per unit	\$2.00
Chrome, 40% and over, f.o.b. cars California, cents per unit	50-55
Magnesite, crude, per ton	\$8.00-12.00
Tungsten, 60% WO ₃ , per unit	16.50-18.00
Molybdenite, per unit for MoS ₃ contained	40.00
Manganese, 50% (under 35% metal not desired), cents, unit	35-40
Manganese ore, 40 to 45%, sells f.o.b. Chicago at 58c. per unit with a penalty of 50c. per unit for more than 8% silica.	

EASTERN METAL MARKET

Owing to interruption of telegraphic communication east of Denver on the day of going to press, it has been impossible to obtain market quotations from New York by wire as usual.

COPPER

Coinage at Philadelphia mint for March was: Half dollars, 462,000 pieces; quarter dollars, 2,620,000 pieces; dimes, 7,050,000 pieces; nickels, 566,942 pieces; cents 6,709,550 pieces. There were also made 10,000 coins for Peru.

During the past year fluctuations in the price of silver have been extreme, ranging from 26 11-16 to 37 1-8d. (\$0.54 to \$0.75 United States gold), the lowest quotation being in January and the highest in May. The coinage demands of the belligerent countries, including the expenditure on military operations in Egypt, East Africa, and Mesopotamia, have been a contributing cause to the remarkable rise in the price of silver, but the rise was chiefly due to the purchases made by the Indian Government, which bought during the course of the past 12 months some \$15,000,000 (\$72,997,500 United States gold at exchange of \$1.8665) worth of silver. The balances in the Indian Currency Reserves were reduced by 16 crores of rupees (\$51,909,330 United States at exchange of \$0.32443) between August 1915 and March 1916, and had to be replenished by large purchases of the metal, the urgency of which has been in no way diminished by the heavy withdrawal of rupees that is still going on.

These demands of the Allied Governments for coinage and of the Indian Government to replace the enormous absorption of silver rupees by the natives of India, where gold was not available for hoarding purposes, have more than kept pace with supplies. Outside sources of supply were tapped; the equivalent of 8,350,000 standard ounces was obtained from the Government of the Philippines in the form of peso coins, and the movement of

silver funds into gold securities necessitated a heavy export of silver from China. During the year under review these exports amounted to about 19,000,000 oz. In addition to the above, about 9,000,000 oz. was exported to India from Hongkong in the form of dollars and subsidiary coins. There is, therefore, no escape from the conclusion that the amount of silver left in China must be barely sufficient for trade requirements; and assuming, as we have every reason to, that there will continue to be a strong demand for the products of China, it would appear inevitable that China must again be a competitor in the silver market.

Foreign tin stocks: The London tin stocks on March 10, 1917, were as follows: Straits and Australasia, 1563 tons; Banca, 247 tons; Billiton, 37 tons; Chinese, 68 tons; and English, 58 tons, making the total 1973 tons, compared with 1896 tons of March 3.

The Liverpool tin stocks on March 10 were as follows: Australasia, 10 tons; Banca, 275 tons; Billiton, 64 tons; and English, 47 tons, making the total 396 tons, compared with 486 tons on March 3.

ANTIMONY

The demand in New York for spot antimony is a little less on account of arrivals having met the immediate requirements, and the nominal quotation is 34 to 35c. for prompt delivery. Forward antimony is still offered at 13 1/2c. Spot needle antimony has realized 13c. per pound. Antimony ore is hardly obtainable and the nominal quotation is \$2.50 to \$2.75 per unit for first-class high-grade ore.

PLATINUM

The price of platinum remains unchanged at \$105 for the soft unalloyed metal, and \$111 for the hard natural platinum-iridium alloy.

Eastern Metal Market

New York, April 11.

Practically all the metals are without feature and lifeless, even more so than last week. There is an absence of any interest and even the official recognition of a state of war has failed to bring about any decided activity.

Copper has continued to decline and is heavy and dull.

Zinc is manifesting considerable weakness which has increased in the last day or two.

Lead is firm and steady with no change in prices.

Tin is less active than for some time but is firm.

Antimony is still nominally unchanged.

Prices for steel for Government war needs have been settled upon with the producers and the prices as arranged are 2.90c. for plates and 2.50c. for bars and structural shapes. At least 300,000 tons are at once involved with still more buying to come later. These prices are no hardship for the United States Steel Corporation, but may be a decided one for some smaller producers. The labor problem is to be a difficult one as time goes on and recruiting increases. Prices are still advancing for pig-iron, finished steel, and old material. Basic iron has gone from \$35 to \$40 at Valley furnaces with Bessemer iron up from \$39 to \$42, while scrap has advanced \$2 to \$3 per ton.

The monthly statement of the Steel Corporation shows the largest unfilled orders ever recorded—11,711,644 tons—an increase of 134,947 tons over those at the close of February.

COPPER

Whether American producers will be called upon to sell large quantities of copper to the Allies for delivery in the last half, and if so at what price, is the dominating influence in the market. Opinions in the trade differ as to the probable price, for the supplying of large amounts is taken for granted. Some think the metal will go at 16.67c. per lb., while others expect a price of 20c. or perhaps as high as 25c. Uncertainty as to the outcome of these factors has exercised a repressing tendency among buyers and the market is heavy and dull. In fact, there are more sellers than buyers and the market has constantly receded the past week. Today nearby and April electrolytic and Lake copper are quoted as low as 33c., New York, with May and June at 32 to 33c. and third quarter at 29 to 30.50c., all New York. Last week future copper—July, August, and September delivery, was obtainable as low as 29.50c., New York, with offerings later at 29c., but little buying was reported. The London quotation for spot electrolytic was unchanged at \$151 yesterday.

TIN

The market is devoid of interesting features and sales have been very light the past week. On April 5 a moderate business was reported as done quietly in future shipments from the East. Early this week a little business was done in spot metal at 54.50 to 54.60c. and more could have been transacted if sellers had been willing. Yesterday there were inquiries for at least 100 tons but no business resulted. The market has assumed a dull tone and the declaration of war has not been thus far a bullish factor. Considerable interest has been taken in the announcement of a new plant to smelt Bolivian tin ores in the United States. A new corporation, the Williams Harvey Co., in which the National Lead Co. has bought a half interest, and which is closely affiliated with the largest tin producer in Europe, the Williams Harvey Co., Ltd., of England, has bought 9 acres of land on Jamaica bay, Long Island, and will at once put up one unit which will produce 300 tons of tin per month. This metal will not come into the general market directly but will be absorbed by the National Lead

Co., already one of the largest users of tin in this country. A saving of at least ¼c. per lb. is considered certain, that amount being the freight on tin from England to New York. The opening of the Panama Canal has made this project possible. Bolivian ore, formerly sent to England around Cape Horn, now goes directly to England through the Canal. The quotation yesterday for spot Straits tin was 54.62½c., New York. The arrivals thus far in April have been 1490 tons, with the amount afloat at 3012 tons. The London quotation for spot Straits yesterday was £216 10s., an increase of over £2 above that of last week.

LEAD

The lead market is unchanged and steady. Very little business has been reported though some was done last week at 9.37½c., delivered at Eastern points, which is higher than the St. Louis quotation of 9.15c. The New York price has stood at 9.35c. the entire week with the St. Louis quotation at 9.15c. A rumor has been circulating that a price of 4.70c. per lb. has been agreed upon between producers and the Government, but its confirmation has not been possible. If anything has been decided it is not generally known. Opinions differ as to just what such a price should be, very few placing it as low as 4.75c. per lb., the average price for the last 10 years. Some regard this as too low—lower than the cost of production for some smelters at present. Some place the expected price at 5.50 to 6c. per pound.

SPELTER

The market is lifeless and weaker. Prompt and April metal can be bought today for 9.75 to 10c., St. Louis, and some even say that this can be shaded. Uncertainty as to the future and an entire absence of demand in any large volume have caused the previously stagnant market to change to a weak one. Offerings are being freely made, some producers appearing willing to sell future metal at a loss, ore prices not showing much change. Export figures are no longer available because of the War, which has not thus far been a bullish factor in this market.

ANTIMONY

There is very little change since last week. The nominal quotation is 36c. for spot metal with a few sales reported at 36 to 37c. Early-delivery metal is somewhat more plentiful than a week ago.

ALUMINUM

Spot metal is still 59 to 60c. for No. 1 virgin aluminum, 98 to 99% pure. The Government has made no purchase yet.

QUICKSILVER

The past week has seen quite an active market for quicksilver, which, though quoted nominally at \$120 per flask, was obtainable at a concession from this figure, and the leading parties reduced their price to \$115 per flask. This price refers to Californian virgin quicksilver.

ORES

TUNGSTEN. One broker reports sales for the week of over 500 tons of tungsten concentrate at \$16.50 to \$18 per unit, depending on the quality. The entire market is more active than for some time, with Europe a decided factor. Italy is reported to have bought 200 tons of ferro-tungsten at \$2 per lb. of contained tungsten, for delivery during the year.

MOLYBDENUM. Because of inability to secure ore, a contract for 30 tons of ferro-molybdenum was cancelled, according to one broker. The ore situation is not satisfactory and quotations are irregular. A new company is making ferro-molybdenum in electric-furnaces at Boonton, New Jersey.

ANTIMONY. The ore continues difficult to secure and therefore the quotation is nominal at \$2.50 to \$2.75 per unit.

BUNKER HILL & SULLIVAN

The Bunker Hill & Sullivan Mining & Concentrating Co.'s report for the year ended December 31, 1916, shows the following: Total ore mined during the year, 475,784 tons, for an operating profit of \$1,867,791.97. The cost of mining per ton of concentrate produced was \$14.74; cost of milling per ton of concentrate, \$3.75. The cost of transportation, smelting, and other incidental expenses was \$38.74, and the total cost per ton of concentrate was \$58.17. Other sources of revenue than ore treated brought the total operating profit for the year to \$2,365,040.31. Dividends were paid during 1916 amounting to \$1,716,750. There are calculated to be still available in the property ore reserves blocked out as follows: In the Stemwinder mine, 9561 tons; in the Sullivan mine, 722,305 tons, and in the Bunker Hill mine 2,721,280 tons, making a total of 3,453,146 tons. The gross surplus valuation of the property, December 31, 1916, was \$45,052,211.50.

COPPER RANGE COMPANY

The directors present the following consolidated statement of the operating companies for the year ended December 31, 1916:

54,747,498 lb. of copper produced and sold at average of 25.28c. per lb.....	\$13,840,167.49
Interest	69,868.51
	<hr/>

	\$13,910,036.00
Mining expenses, including smelting, freight, marketing, etc.	4,771,398.83

EDITORIAL

T. A. RICKARD, Editor

SPADE and shovel, the spade of the farmer and the shovel of the miner, must be plied lustily in order to sustain our national effort in the War. The pick of the miner will aid the pick of the sapper in digging the road to peace.

THE long arm of coincidence has brought our editorial on Mr. Kinzie's article discussing 'Methods of Mining' alongside our regretful comment upon the subsidence at Treadwell. Truly this question of how to work big low-grade orebodies is a vital one.

SEVEN billions is an enormous sum of money, but the bond issue of today is easier for the United States to digest than the \$500,000,000 raised in 1862. Then the wealth of the nation was \$16,000,000,000; now it is \$230,000,000,000. The population now is three times what it was then. The Government had to pay 6% in 1862; it will pay 3½% in 1917.

JAMES A. PATTEN, Arthur Cutten, and other traders at Chicago have announced that they have ceased to speculate in grain, as "an act of patriotism." This is a commendable act, for it does mean a financial sacrifice. To these men speculation is meat. Their action is far more patriotic than that of the worthy people who are willing to operate their manufactories on a 10% profit guaranteed by the Government. At that kind of sacrifice one may smile cynically.

METAL prices have been inflated during the course of the War to a degree that threatened a dangerous collapse of industry—and of such speculation as stimulates the mining industry in particular—when the necessary readjustment begins. The recent sale of copper to the Government at a price that is the average for the last decade indicates how the readjustment may be effected without any panic. It will enable the big producer to co-operate with the Council of National Defence not only in procuring a supply of copper and other metals at a reasonable price but it will permit Mr. Bernard Baruch to work with his fellow-speculators and market-operators in bringing prices back to a normal level, that is, to one likely to hold when the War ends.

DAYLIGHT-SAVING is a most desirable economy. A plan that has met with favor abroad, and that is threatened in the United States by a bill pending in Congress, is to play a huge national joke, setting the clock ahead and scaring people out of bed at 5 a.m. under the belief that it is really 6. The sentiment of the victims

toward the time-piece convicted of telling a lie regarding the relation of the sun to the local degree of longitude, is likely to be expressed in explosive language. Wherein the scheme will save more time than by merely blowing the whistle earlier on summer mornings is difficult to see. In all seriousness it would seem that the end sought might be attained with less disturbance of the settled order of things by a general agreement to begin work at an hour that would take advantage of the earlier dawn. The farmer has always done this without juggling with the clock. These changes, moreover, would disarrange the railroad schedule twice each year, and in railroad operation the familiar time-table is the safer. The idea is more amusing than important.

IN the death of Frederic Anton Eilers this country loses a metallurgist and a man to whom the mining industry is under lasting obligations. The history of Western smelting cannot be written without paying tribute to his genius as a leader. He combined the faculties of a progressive man of affairs with those of a highly trained technologist possessed of the constructive imagination that opens new paths for progress. He has justly been called the father of American lead smelting. Seventeen years after landing in this country he had established the Germania smelter, near Salt Lake, and three years later, in 1879, he was a dominant figure in the Leadville district. His grasp of the opportunities offered by the West found its expression in the smelter at Pueblo, Colorado, built in 1883 by the Colorado Smelting Company, of which he was president. Thus was founded an enterprise at a point chosen with such rare understanding of the relations of available supplies of ores and fuel, and of transportation both for raw materials and finished products, that the works then established became conspicuous among the smelting plants of the United States. The several enterprises created by him constituted one of the most important groups entering into the combination in 1899 that made the American Smelting & Refining Company. Anton Eilers represents one of several distinguished engineers and metallurgists attracted from Germany by the discoveries of great mines in this country at a time when we lacked men capable of dealing with the scientific problems presented. He was born at Nassau, Germany, in 1839, graduated from the Mining School at Clausthal and the University of Göttingen, and threw his talents into the unfolding of the metal resources of the United States in 1859. To him the War seemed a terrible calamity from the first and to him the final participation of the United States in the contest against Germanic aggression must have been a bitter blow. It is

one of the tragedies of our time that citizens so useful and honorable, after a life of effective service in the cause of American industrial and technical development, should find themselves pulled by opposing ties. To the old the undermining of faith in the orderly development of human affairs is a shock such as the young, with their optimism, are spared. To us and to many of our readers the passing of Anton Eilers is the breaking of a link with the past, the close of a heroic period in technology, and the loss of a greatly honored friend.

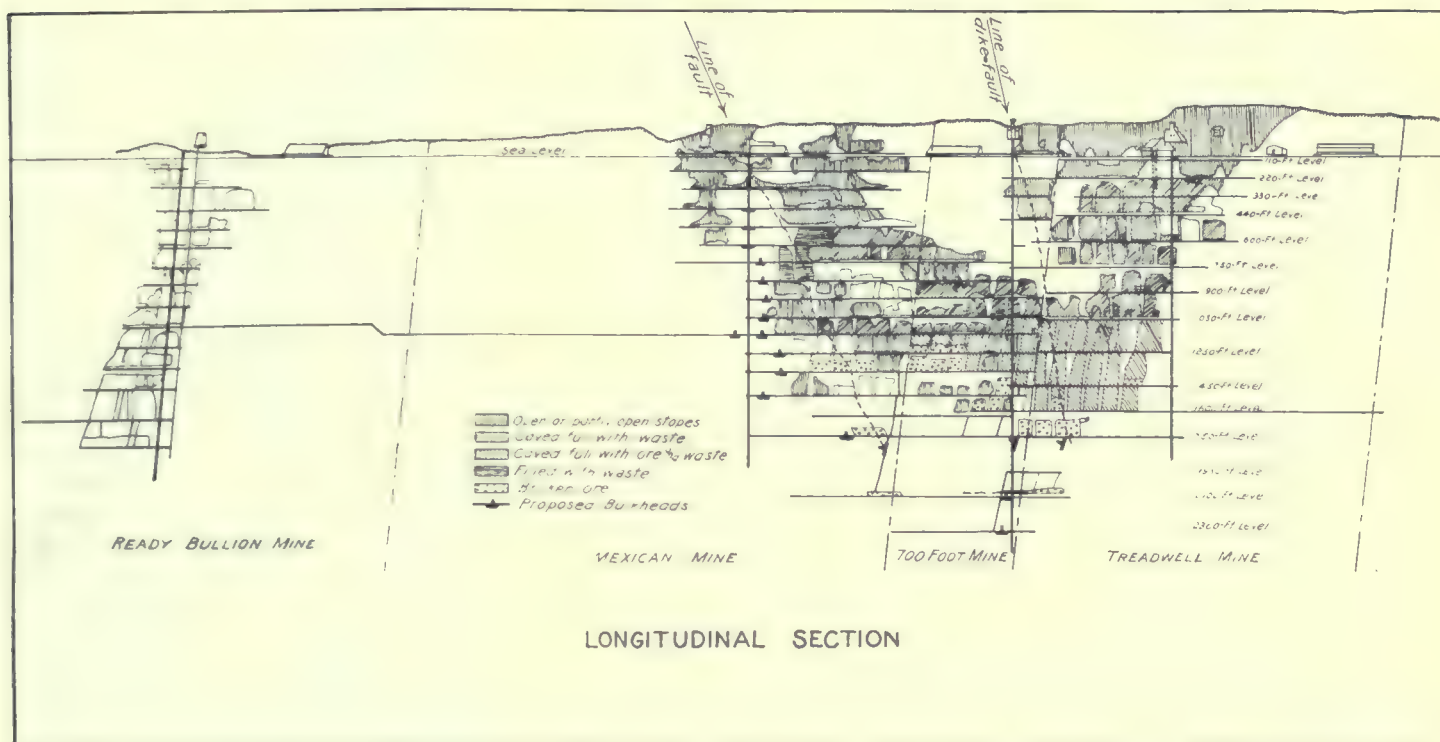

The Treadwell Subsidence

Late on the night of April 21 the workings of the Alaska Treadwell, Alaska United, and Alaska Mexican mines had to be abandoned on account of an inrush of water from the sea, that is, Gastineau Channel, the strait separating Douglas island from the mainland. Fortunately ample warning was given, so that no lives were lost. The locality of the subsidence is shown on the accompanying map, it being the rounded space marked 'Subsidence Area' extending for 250 feet on each side of the boundary between the Treadwell and the 700 Ft. mines. An intermittent settling of the ground in this locality has been noted since July last. Another area of subsidence is shown over the Mexican mill-site, but this has given no sign of movement recently. These two danger-spots are immediately related to the respective faults along the two dikes, as indicated on the map; both are on the edge of the old shore-line, which, by discharge of tailing and other filling, has been extended about 500 feet into the channel, as the map shows. The final collapse came suddenly, but watch had been kept at each known area of settling so that the evidence of further caving was detected on the surface and reported in time to permit the men to escape from underground. Then the water broke through the cracks and filled the three mines that are contiguous. Luckily the Ready Bullion mine is separated from the others, and the only connecting working, the 1350-ft. level from the Mexican, had been carefully bulkheaded in two places. The latest report states that the bulkheads are holding, so that the Ready Bullion mine is likely to be saved. To what extent the position may be retrieved cannot be known immediately; if the subsidence does not go too far, that is, if the caving does not reach out along the fault so as to present a larger opening to the sea-water, there will be a chance of surrounding it with a coffer-dam, and thereby re-winning the three mines now completely drowned. If that cannot be done then the Ready Bullion shaft can be sunk and drifts extended to tap the virgin ground under the lost workings of the three other mines. This deeper ground has been giving promise of improvement in gold-content, as explained in our last issue, and it is protected from caving by several hundred feet of unstopped rock. The staff, more particularly their chief, Mr. F. W. Bradley, are not the kind of men to throw up their hands helplessly so long as engineering skill can save the mines or any part of them. Fortunately Mr. J. H. Mackenzie

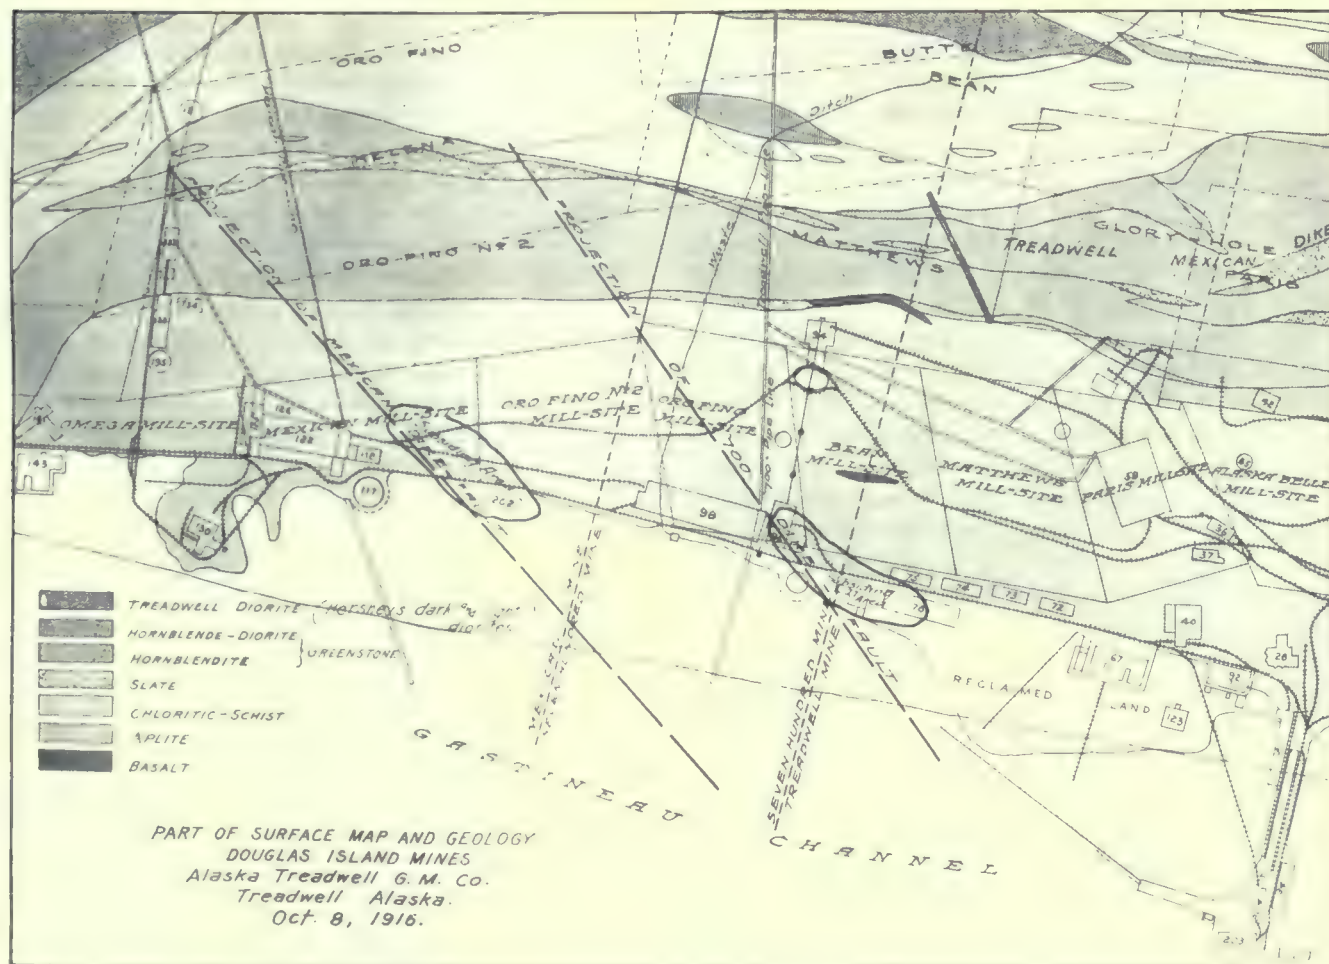

happens to be at Juneau just now and his mature experience is at the service of the local management. Our readers will find further information on the subject in our issue of February 10, this year. The three mines immediately affected by subsidence and flooding have produced 22,661,748 tons of ore yielding \$54,886,968 in gold, from which a profit of \$23,072,567 has been earned from August 1885 to June 1, 1916. The reserves of ore amounted to 6,000,000 tons, besides about as much more in pillars and caved ground. The Ready Bullion mine, of the Alaska United company, has produced 3,802,299 tons, yielding \$7,910,491, of which \$1,966,011 was profit. The three companies have distributed \$21,337,651 in dividends during their lives. We give the hand of sympathy to the members of the staff at Treadwell, to whom the event must seem calamitous. As regards the force of workmen, it happens that a scarcity of labor exists in south-eastern Alaska, owing largely to the work on the Government railway from Anchorage, so that any men discharged from Treadwell will be welcomed at Juneau, where the shortage of labor threatened seriously to interfere with the success of the Alaska Juneau operations, now coming to fruition.

Methods of Mining

No part of the technology of mining is so scanty and unsatisfactory as that which deals with the breaking and removal of ore underground. The reasons for this lack of information are not far to seek. In the first place the large-scale exploitation of mines is comparatively recent; there was very little of it in the days when the elders in the profession were students in a school of mining. However, the newness of the subject would not have prevented the growth of writings concerning it except for the fact that underground methods of work are difficult to describe and those most familiar with the details are usually least able to write with pleasure to themselves or with profit to others, while among those that can write skilfully very few have had much to do with the more intensely practical phase of the subject. Exceptions fortunately exist. In this issue we publish the second part of an article by Mr. Robert A. Kinzie, for ten years the general superintendent of the Alaska Treadwell group of mines. Mr. Kinzie is not only familiar with the technique of underground work through long experience as the manager of big mines, but to his scientific training at the University of California he has added the ability to write clearly, an ability, we venture to say, not acquired by inspiration from on high, for that is not the source of literary skill, but by a painstaking and intelligent effort to use words as if they were weapons of precision. Indeed, we recommend the article on 'Methods of Mining Big Orebodies' to the younger members of the profession as one of the best examples of good technical writing that has come under our notice. As an editor we would gladly offer libations to Clio, or whichever muse it be that presides over this part of human endeavor, if only we could have more writing of the same kind.

THE TREADWELL GROUP OF MINES. THE AREA OF SUBSIDENCE IS AROUND THE DIKE-FAULT IN THE 700 FT. GROUND.

GEOLOGIC MAP OF THE TREADWELL PROPERTIES. THE LOCALITY OF THE SUBSIDENCE IS THE ELLIPTICAL AREA ABOVE THE WORD 'CHANNEL.'

Mr. Kinzie's article discusses the method of mining most suitable to the conditions obtaining in the mines on the Alaskan mainland, near Juneau. These mines have come into prominence during the last three years by reason of the enormous scale on which the Alaska Gold Mines, controlling the Gastineau group, which includes the old Perseverance and contiguous properties, is being exploited, also on account of the expansion of the Alaska Juneau enterprise, which is in the hands of the highly capable engineers identified with the management of the Treadwell group on the adjacent island of Douglas. The first condition to consider is the low gold-content of the ore, the average being \$2.55 in the Treadwell mines, \$1.50 in the Gastineau, and \$1.60 in the Juneau. Next is the width of ore, varying from 400 feet in the Treadwell dike to 900 feet in the Gastineau-Juneau lode-channel. Any method of extraction must be based on a careful diagnosis of the geologic structure. Mr. Kinzie describes this with admirable clearness. The zone of mineralization is as much as 3000 feet wide, but the workable portion is about 900 feet wide. This is not a homogeneous orebody; it consists of alternating bands of ore and waste dipping at a steep angle, ranging from 60° in the old Perseverance workings to 30° on Mount Juneau. In the Juneau mine the dip is 55°. The ore is either in schist or meta-gabbro, both of which have been crushed and sheared, and then penetrated by veinlets of gold-bearing quartz. The gold is found in the quartz, but only where the sulphides of lead and zinc abound. The problem is to remove as much of the gold-bearing quartz with the least amount of barren rock, and to do it on a scale sufficiently large to make money out of a mill-feed that assays \$1.75, or even less, per ton. The Alaska Gold Mines company is now treating 9000 tons per day and expects eventually to treat 14,000 tons per day, whereas the first unit of the Alaska Juneau mill was started last week, crushing 1000 tons per day, an amount that is to be increased gradually to 8000 and possibly to 12,000 tons daily. To supply mills of this capacity with ore yielding a profit is a task fit for an engineer of the most resourceful type. It must be done with due regard to the safety alike of the mine and the men. At Treadwell, as our readers are aware, the method of excavation is what is known as 'back-stopping,' that is, by under-cutting the orebody and stopping the ground by blasting from the backs, the men standing on the broken ore as it accumulates under-foot. No aid is expected from caving, which indeed is not desired, all the breaking being done by mechanical methods; in short, by man and not by nature. Apparently Mr. Kinzie considers that, of the various methods he has described, the second and fourth are best adapted to the Juneau ground as at present developed, and he recommends the fourth method for the Gastineau. The last method was developed by the late John R. Mitchell in the course of his experience as superintendent of the Perseverance mine and in friendly consultation with Mr. Kinzie at the Treadwell. To Mitchell, a fine type of mine-captain, will be due a large measure of credit for the successful exploitation of these Alaskan low-grade

orebodies, and it is deeply regrettable that he did not live long enough to see the result of his pioneer work. His first stoping in the slate, above the Alexandra adit, was started on a back-stoping or Treadwell plan and he soon got into difficulties, which he was quick to recognize, with the result that he modified his practice in order to lessen the obvious danger, it being impossible to put men to work under the hanging wall. Thus he changed gradually to a method of blasting from the foot-wall, allowing the hanging to cave at the proper time by leaving a thickness of ore, ranging from 2 to 25 feet, to delay the collapse of the hanging until the broken ore had been drawn. The point most emphasized in Mr. Kinzie's article is the use of bulldozing-chambers in connection with back-stoping. This chamber may be defined as a recess where-in the breaking of large pieces of rock may be performed by men under cover. Mr. Kinzie evidently has a strong belief in the efficacy of such an accessory to the stopes as affording a means for reducing the cost of mining and decreasing accidents to the men. The bulldozing-chamber gives a fine chance to confine the use of explosives to a limited range and away from places where men are operating machine-drills. This method also facilitates proper ventilation, for the chamber diminishes the proportion of fume and smoke in the stopes. It must be remembered that the author of the article, besides his work at Treadwell, was general superintendent of the Juneau for nine years and has been enabled to test this system on a fairly large scale. His treatment of the subject is not academic. Indeed, every method discussed in the article has undergone practical test by the author himself, for which reason his suggestions are of unquestionable value. Mr. R. G. Sampson in his recent article, appearing in our issue of April 7, described a method resembling Mr. Kinzie's third scheme, but Mr. Sampson's method is adapted particularly to orebodies of the horizontal type, under an overburden, as at Ray, especially in relation to the recovery of stope-pillars. He refers to the loss of ore incidental to this kind of mining, and on this we may remark that such loss can be decreased by stoping from intermediate cross-cuts, so as to remove the stope-pillar before it is surrounded by the waste, which dilutes the broken ore. The reclaiming of pillars is a large detail, too often overlooked or insufficiently regarded. Upon it, of course, depends the success of the method. It should be unnecessary to emphasize this phase of the subject. The future production of gold, copper, and lead, as of other metals probably, will come from immense masses of low tenor similar to those constituting the Juneau and Treadwell mines, which differ from the disseminated copper mines in Utah, Arizona, and Nevada in that they are based on the exploitation not of nearly horizontal layers or zones of ore but of the steeply inclined type of lode. Hence any information on the subject is of the greatest value to the engineering profession. Therefore we invite discussion of Mr. Kinzie's article, knowing that intelligent criticism is the kind of compliment that he will most appreciate, as we also shall most welcome.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Hogging Mineral Land

The Editor:

Sir—The gold output of the United States during 1916 decreased over \$8,000,000, and the current year will probably record another decline. The PRESS has devoted considerable space to prospectors and prospecting, giving some of the reasons why the search for gold, for instance, has fallen off. A recent trip through Mariposa county, California, enlightened me on another phase acting against the discovery of new mines, namely, the 'hogging' of large areas of mineralized land by a few companies. Motorists and others understand the phrase 'hogging the road,' so miners will see the significance of the title to this note. Mariposa county is the most southerly of the Mother Lode counties, with an area of 1463 square miles, and while the counties to the north are busy, Mariposa is decidedly dull. Why? Three instances should suffice to answer this: One is the Mariposa grant of 44,000 acres of patented ground, on which no mining is being done. Near Coulterville the Merced Gold Mining Co. has watchmen only looking after its Mary Harrison and other claims extending over a mile on the Mother Lode. This patented ground has not been worked for 15 years or so, although it was recently sampled. The Peñon Blanco and other patented claims of the Oro Rico Mines Co., having a length of over a mile on the Lode, have not been operated for five years or so, and employ only a watchman. Leasing on these three large properties is not encouraged, neither is prospecting; consequently the county suffers. Conspicuous outcrops are traceable for miles, and should contain shoots of gold ore. Such a condition should not be allowed to continue. Some system of taxation or labor requirements, such as is enforced in Australia, would compel the companies to give up part of their ground, or encourage prospecting and leasing on easy terms. This hogging the land is a great detriment to the industry.

Another drawback to mining in Mariposa county is the lack of electric power. Two companies supply part of the region, but they cannot be expected to extend their transmission-lines unless mining expands. Those companies which are at work must suffer this power shortage until mining operations are started on the large patented areas. Fuel is scarce in these districts, so electricity is what is needed.

In the county at present the Champion, McAlpine, Mountain King, Virginia, Ruth Pierce, and other mines are being actively worked or are under development. Near La Grange a dredge is working along the Tuolumne river, while near Merced Falls the Yosemite Dredging

Co.'s boat is digging profitably in river-flats, some of them agricultural lands.

Something is necessary to enliven gold mining in this promising county, and the elimination of large holdings of patented ground would help considerably.

M. W. VON BERNEWITZ.

San Francisco, April 10.

Good Work Underground

The Editor:

Sir—I have been reading various articles of late in your paper referring to what should constitute a shift's work, that is, the footage a man should drill per day, the distance he should tram, the distance a crew should drive in a tunnel, and the bonus system as compared with contract.

I will give you an actual case covering all these points. We are driving a cross-cut tunnel $4\frac{1}{2}$ by 7 ft. in the clear. The rock is hard slate and dry, with only occasional small seams or watercourses, which soon drain off after cutting. During the month of March we drove 367 ft. There are two men on a shift and they use a jack-hammer without the bar or water attachment. They use muzzles only to protect them from dust. We are working three shifts of 8 hours each. The two men remove the dirt left from the round of the previous shift and put in their round of holes to a depth of $4\frac{1}{2}$ ft., which is all the succeeding shift can handle and get their round in within their time. They average 8 holes per round, or about 32 ft. They lay their track up to the face, place the turn-sheet on top of the track, and blast on top of it. Then the next shift is ready to go to work.

Our ventilation is a small jet of compressed air turned into a 6-in. thin galvanized-iron pipe. The jet is carried all the time as close up to the face as possible without being blasted out. The tramping distance of last month was at the start 1020 ft. and at the end of the month 1387 ft. The two men on shift change with each other on each car-trip. The car holds 26 cu. ft. and they heap about three cubic feet more on top. Two men follow up with the timber. They cut and drag in their timber on the snow a distance of about 300 ft. and put in on an average of about 50 sets per month, about one-third of it lagged up on both sides as well as the top. A mechanic comes to the tunnel every other day and puts in the needed ventilation-pipe, moves the jet forward, and adds air-line.

We use about a half a box of dynamite per shift. We had trouble with mis-fires for a while, but as T. T. Edwards wrote in your issue of March 24, there are only

four reasons for mis-fires. We investigated the four reasons and found defective fuse and caps. We also find that there is a big economy in using strong caps. We use the best fuse on the market and an 8x cap with 40% gelatine powder and now have no trouble with mis-fires or 'stinkers.' Our primers are made and placed just as Mr. Edwards advises.

We pay a bonus to the six men of \$3 per foot for all the footage they make over 210 ft. for the month. The bonus is divided among the six in proportion to the days they put in during each month. They are paid \$4 per day for their 8 hours work. Although we are 40 miles from the nearest town, we have no difficulty in replacing a man on this tunnel-work, as soon as anyone wants to lay off. We think we have come pretty close to the record for six men at that distance of tramming and under the conditions as described. I must state also that during the month, for various reasons, four shifts failed to get in their rounds, which meant 367 ft. in 87 shifts or 4.218 ft. per shift.

Do you think we approached a record?

J. A. WILLEY, Superintendent.

The Bachelor Mine, Stemple, Mont., April 4.

Nitrogen Gas in Metal Mines

The Editor:

Sir—The article by E. Steidler of the Bureau of Mines in your issue of March 11, 1916, describing a gas of almost pure nitrogen which occurs in the Tonopah-Goldfield district of Nevada, reminds me of several occurrences of what appears to be a similar gas which has come under my notice, and if members of the mining profession would record their observations of the occurrence of this gas it might be found to be of more frequent occurrence in metal mines than Mr. Steidler infers. Should the description of the gas occurrence be accompanied by a short description of the geology of the district in which it is found, the accumulation of such information would undoubtedly lead to important results in the elucidation of the complex problem of ore genesis.

The first time that I noticed an accumulation of an inert gas lighter than air (other than that found in workings in recent lava-flows in which the oxygen of the air had been removed by chemical combination with the wall-rocks) was in the Brown Bear mine, Trinity county, California, during the fall of 1914. The locus of the gas accumulation was a blind raise from a prospect-adit driven into the hill on the east side of the gulch in which the old Brown Bear mill had stood and a short distance farther up the gulch. The line of demarcation between the inert gas in the raise and the ordinary air in the adit was sharp. The raising of the candle an inch above the point at which the gas was encountered was sufficient to extinguish it. This raise was full of the gas right down to the bottom of the timbers in the roof of the adit. I was told that this same gas was found in some of the raises from the main adit,

but this I did not verify, although I was in some of them, but not to their tops. The Bragdon formation, of Carboniferous age, is the only sedimentary rock in the district. This unconformably (?) overlies a greenstone ('meta-diorite' of Diller), which has been assigned to the Devonian. These two formations have been faulted and intruded by dikes of a granitic texture, apparently apophyses of the grano-diorite mass a mile or two to the south, which is of supposedly Jurassic age. The ore deposits were formed subsequent to the intrusion of the dikes, but their exact age is uncertain and may be as late as the Pliocene, though probably of Miocene age.

The other occurrence of the inert gas observed was in the Cliff mine on the north shore of Port Valdez about nine miles west of Valdez, Alaska. It occurred in the tops of two blind raises, mostly above the portion of the raise where it was divided into a ladder-way and a rock-chute. The line of separation between the gas and air was not definite. There was usually several feet of a zone in which a mixture of the gas and air took place which was indicated by the dimming of the candle-flame. On further advance the flame was extinguished. There is but one geologic formation in the district—the Valdez formation—a metamorphosed series of Paleozoic (?) sediments which originally were slates and sandstones, but which now have a predominantly schistose structure. No igneous rocks occur near the mine. The nearest rocks of that type are some dikes near the mouth of Mineral creek, about five miles east. There are like intrusions to the west at about the same distance. The deposition of the gold took place previous to the movement that slickensided the vein. The striation from this movement is horizontal or nearly so, and records what appears to be the last movement of the rocks, of any magnitude, along the vein. However, the region is subject to seismic disturbances, and earthquakes of considerable magnitude are not infrequent.

The Bragdon formation and the Valdez formation, especially the latter, are composed of rocks that have reached chemical equilibrium, at least to the extent that they do not combine with the oxygen of the air with which they come in contact, and thus do not deplete the air of its oxygen content. In the Cliff mine between the two raises in which the inert gas occurs, there are five other raises penetrating the same character of formation and these are as favorably situated for the accumulation of the gas as the two in which it occurs, but they are entirely free from it. Many other raises and tops of stopes in this mine are also as well situated for gas accumulation as regards lack of ventilation, and if the rocks were absorbing the oxygen from the air they would be reservoirs filled with the gas; but this is not the case.

That this gas is exuding from a deep-seated source at certain zones from the rocks into which the mine-workings have penetrated is borne out by the field evidence, and my observations lead me to believe that it is one of the products of magmatism.

JACOB W. YOUNG.

Oakland, April 7.

Chemical Preparedness

California is in more than one way a treasure house for the nation. Fruits, vegetables, and grain grow in abundance in our fertile valleys. In the mountains of the State there are hidden rare minerals—besides gold, copper, and silver—that are able to yield some of the metals most needed in the iron and steel industries. With true Western lavishness we have skimmed the cream and let much of the wealth of the State go to waste. The chemists are preparing to stop this waste. They are preparing to find means by which wastes can be utilized and made valuable. A complete survey of the State's chemical resources is being carried out by the American Chemical Society; and in conjunction with this survey, the chemists have taken an active interest in a bill presented to the legislature to provide for the mobilization of the chemical resources of California for the purpose of State and National defense, to encourage the development of chemical industries, and to make an appropriation therefor.

This Bureau of Chemical Research would be associated with the University of California, just as the Bureau of Agriculture is doing excellent work through its close affiliation with the University. Those that are acquainted with the chemical conditions appreciate the big problems that confront them. For example:

Gold extraction in the mines today is severely hampered and in many cases stopped by a lack of cyanide. The citrus growers are suffering for the want of the same chemical, which is used in fumigating their orchards. The Bureau could help to correct this deficiency. Enormous quantities of agricultural waste from the farms are disregarded, although they contain elements from which valuable substances, such as alcohol, oil, and fertilizers, can be derived. The wood-waste from the large lumber operations in the State, constituting in some places a fire menace to the adjacent timber-stands, contains turpentine, alcohol, and other chemicals, as well as charcoal, each of them products of vital importance to industrial development.

These are matters of State wealth, as well as National preparedness, which the State Bureau of Chemical Research will be eminently fitted to investigate.

The best means by which our iron ores could be made available would be studied. Our National, as well as State, defense depends on the readily available supply of iron. Together with the charcoal produced from wood-waste, hydro-electric power obtained in the mountains, and iron ore, we might become independent of the world for our iron needs.

In the proposed bill is a special proviso made by which the activities of the Bureau will in no way interfere with the private practice of chemists of all descriptions. No employee shall engage in any private practice or receive any remuneration for work, except his salary from the said Bureau.

The local section of the American Chemical Society passed a resolution at a recent meeting urging the pass-

age of this bill and also that a bill be presented before the legislature to protect the platinum supply of the country. Platinum is used extensively in the chemical arts and is also used in the jewelry trade. This bill would prevent, during this crisis, the use and sale of platinum in jewelry. Our national preparedness is dependent to a great extent on the available supply of platinum, since it is essential in the manufacture of some of the ingredients needed in every pound of explosives used on the battle-field.

Katanga Copper

A huge leaching plant and an electrolytic refinery are to be built as rapidly as possible for the Union Minière du Haut-Katanga at Elizabethville in the Belgian Congo. The plans are now being drawn in New York by H. Y. Eagle, S. Ward Haas, and P. E. Weldy under the supervision of Archer E. Wheeler, the consulting engineer for the company. All of the above engineers were formerly with the Anaconda Copper Mining Co., Mr. Wheeler having been superintendent of the Boston & Montana reduction works at Great Falls before being called several years ago to the managership of the Union Minière. The designing of the projected plant will require about six months, so that the actual construction cannot well be started for more than a year. The plans include the development of water-power. Mr. Wheeler has been conducting experiments on the leaching of the Katanga ores since his status was changed from that of manager to consulting engineer in 1914. The capacity of the plant will be about 110,000,000 lb. copper per annum. The original reduction plant consisted of 5 blast-furnaces, to which two more were added, giving a total capacity of about 1000 tons of ore daily, the output of bar-copper for 1915 having been 31,450,000 lb. The ores are oxidized, and in order to introduce leaching methods it will be necessary to bring sulphide ores from other districts in order to make the needed sulphuric acid. Before the outbreak of the War the developed tonnage of the Katanga deposits was reported to be 6,026,500 tons, of which one-fifth averaged 15% and the remainder 7% copper. The probable ore, down to water-level, was estimated at 40,000,000 tons, with an indicated copper content of 8%. The mines are in a well defined copper belt 200 miles in length, on which over 100 distinct deposits of copper ore are known to exist.

AT THE LONELY REEF MINE, in Rhodesia, hand-dressed felsitic rhyolite pebbles were tried as a substitute for Danish beach-pebbles, and the rhyolite pebbles were found to give a much higher grinding efficiency than the Danish pebbles. The rhyolite rocks were dressed by natives, and cost, ready for use, \$5 per ton. Rhyolite suitable for this purpose should be firm and dense, with little tendency to break up into angular fragments. All rhyolite therefore is not suited to use for grinding in pebble-mills.

Mining Engineers and Belgian Relief

During this war the work of the mining engineer has received recognition on more than one battle-front, notably the tunneling corps of the British army. In the underground excavations leading to the planting and explosion of mines we are reminded of the fact that the word 'mine' among the Romans had a military significance before it had an industrial meaning. The word 'minatory' preserves that sense. Several members of our profession have lost their lives in military mining and many more have distinguished themselves. Among them we may mention Mr. Ralph Stokes, now a major, who enlisted in the Royal Engineers and then won a commission, rapid promotion, and the military medal. Another is Mr. Gelasio Caetani, serving with the Italian engineer corps, who is famous among his countrymen for the Col di Lana affair, in which he exploded a mine so successfully as to destroy many of the enemy and win an important position for his own side. But the object of this writing is to dwell not on the destruction of life in warfare, but to pay tribute to the saving of innocent lives by the organized effort of mining engineers in Belgium and France. We publish photographs of three men conspicuous in the work of the Commission for Relief in Belgium. The portraits will gladden the eyes of many of our readers. Mr. H. C. Hoover has won enduring fame by his big-mindedness, his executive ability, and his beneficence, all of which were applied to mitigating one of the world's worst tragedies. Born in Iowa only 43 years ago, he graduated in mining engineering in 1895 from Stanford University, of which he is now a trustee. Alert, energetic, and perspicacious he achieved prominence as a mining engineer when in his early twenties, while a member of the staff of Bewick, Moreing & Co., in Western Australia. He became a partner in the firm in 1902, and remained in partnership until 1908, doing notable service in quickening the intelligent exploitation of mines in Australia. In 1899 he was chief engineer to the Chinese Imperial Bureau of Mines and took part in the defence of Tientsin during the Boxer disturbances a year later. At the time of the invasion of Belgium by the German army he was a mine operator in London, acting as managing director or chairman of a number of important British mining companies in Australia, Burma, Siberia, the Yukon, and South Africa. He occupied an enviable position, being not only a rich man and an enterprising capitalist, but the leader of the American colony in London and always honorably prominent in Anglo-American affairs. When the outbreak of war brought hardship to Americans traveling in Europe, he organized a Refugee Committee that proved of inestimable service to thousands of stranded people. In this work he was aided by a number of other American engineers, among whom Edgar Rickard, John Beaver White, John L. Hoffmann, and M. K.

Shaler may be mentioned. Then came the Belgian horror. The pitiable plight of a brave people, invaded without excuse and despoiled without compunction, appealed to him. He proceeded at once to do what he could to help them and soon created a wonderfully competent organization, the Commission for Relief in Belgium. How great a service he performed the world now knows,

H. C. HOOVER

but it is not known to the general public how intensely he felt the tragedy and how whole-heartedly he devoted his time, ability, and money to a great benefaction. The success of the work speaks for itself; it is due in the first place, of course, to the fine spirit that prompted the effort, but it is owing in large measure to the experience he had obtained while managing large mining operations from a distant base and among diverse peoples. Mr. W. L. Honnold, the director in America, joined the Relief Commission at the conclusion of a successful career in South Africa, where he had been 13 years an engineer and manager of big mining enterprises, notably the Brakpan. He was about to take a holiday when the call

came to work for the unfortunate Belgians. He went to Belgium and then had charge of the London office before taking charge of the New York office of the Commission. Mr. Honnold is a graduate of the Michigan College of Mines and practised as a mining engineer in California and Colorado before going to the Transvaal. Mr. Edgar Rickard is a mining engineer also, having graduated from the University of California, and was manager of the Triunfo mine in Mexican California for seven years before becoming business manager of the MINING AND SCIENTIFIC PRESS. When the War began he was business manager of *The Mining Magazine* in London. He co-operated loyally with Mr. Hoover from the first in his

Mr. Hoover's direction. What the effect of American participation in the great conflict will be on the fortunes of the Commission is not yet known; it is to be hoped that the United States government will grant an adequate subsidy, so that American financial assistance may compensate, however inadequately, for the withdrawal of the American staff—whose ability, much more than money, has been our gift to Belgium. Of the financial contributions, so far, the less said the better. It is nothing to be proud of. Nevertheless the C. R. B. has been an American undertaking, splendidly carried out, and it should continue to receive material support. Meanwhile the ability shown by Mr. Hoover and his co-

W. L. HONNOLD

EDGAR RICKARD

work for American refugees and the Belgian people. He served as an honorary secretary of the Commission in London and is now assistant-director in New York. The French representative of the Commission is Mr. Louis Chevrillon, another mining engineer well known in Mexico and in Colorado. Just now the work of the C. R. B. is particularly difficult owing to the withdrawal of the American staff in Belgium and the indiscriminate destruction of shipping, not even food-ships of the Commission being spared by the submarines of our unscrupulous enemy; but it cannot be emphasized too much that the work of the Commission is being continued loyally and efficiently by its Dutch and Spanish friends under

adjutors had commanded such respect that he has been asked by the National Defense Council to become Chairman of a Food Bureau in the United States. This new and important duty he has agreed to undertake and we have no doubt but that he will be free to command the services of the engineering profession in this country in his national task, but if he voluntarily surrenders personal control of his great work in Belgium and France in order to assume this new responsibility, our Government should at least see to it that sufficient funds are set aside, out of the big bond issue, for taking care of the benefaction to which Mr. Hoover has devoted himself for the last three years.

Methods of Mining Big Orebodies—II

By ROBERT A. KINZIE

SECOND METHOD. This method of mining is applicable to stopes in meta-gabbro when the ground has been somewhat faulted and crushed or in mixed meta-gabbro and slate. It is particularly adaptable to the ground in the western portion of the ore zone. Fig. 3, 4, 5, and 6 illustrate in a general way the method to be described.

The orebody is divided into blocks, with levels at intervals of 200 ft. Each level is connected with a ventilating-shaft and ore-way placed in the foot-wall ground, as described under the first method.

A level is started by driving a cross-cut through the orebody from 'foot' to hanging wall. Drifts are then run in opposite directions from the cross-cut. One drift is run in the foot-wall waste-rock, parallel with and about 20 ft. from the foot-wall; another drift is driven in the hanging-wall waste-rock, parallel with and about 20 ft. from the hanging wall. These drifts are then connected by cross-cuts driven at right angles to the strike and spaced 70 ft. centre to centre. As the cross-cuts are run, chute-raises are put up to the level of the proposed floor of the stopes from both sides of the cross-cuts.

The chute-raises alternate on each side of the cross-cuts so that they have a spacing of 50 ft. on each side of the drift or a final spacing between chutes of 25 ft. At a distance of 25 ft. above the level and over the level cross-cuts, stopes are cut out 30 ft. wide. The length of the stope being equal to the width of the orebody.

Between the stopes, pillars 40 ft. wide are left. The bulldozing-chambers are cut out in the stope-pillars, spaced 50 ft. on centres along the side of the stope. These bulldozing-chambers are cut much smaller than in the First Method so that they will not unduly weaken the pillars.

The 30-ft. stopes are carried up to and connected with the stopes on the next higher level in the manner described previously.

The ore in the 40-ft. pillars is removed in two ways. First, the alternate or stoped pillars, namely, No. 3 and 5, etc. (Fig. 3 and 4), the odd-numbered pillars are drilled and blasted down gradually as the broken ore in the stopes is drawn. This work is done from the man-way cross-cuts previously driven from the foot-wall manway-raises through the pillars. This work is started from the top man-way cross-cut at the hanging wall where the pillar is cut free. (See Fig. 5 and 6). The work then proceeds retreating, drilling up, down, and on each side, and blasting the ore so that it will mix with the broken ore in the shrinkage-stopos. The machine-drills and men are always in the man-way cross-cuts, protected from the falling ground. When work on the top man-way cross-cut has proceeded a sufficient dis-

tance, the second is started, and so on until the ore in the pillar is removed.

After the odd-numbered, or stoped, pillars have been removed to within 15 ft. of the back of the intermediate level and all the ore has been drawn, the work of removing the ore in the even-numbered pillars is started.

This work can be done in a number of ways, depending on the character of the ground. If the ore in the pillars has been shattered or crushed, it can be reclaimed by blasting out the bottom of the intermediates and allowing the pillar to cave. The ore is drawn out through the chutes in the bulldozing-chambers and shrinkage-stopos. If the ground will not cave, it may be necessary to either carry up a narrow stope through the middle of the pillar or shatter it by placing heavy blasts in raises run from the intermediate cross-cut to various points in the pillar, thus weakening the pillar and causing it to cave.

When using this system, it is necessary to begin removing the pillars at the outer end of the top level and work in and down, although development and stoping may begin anywhere. It is also of prime importance that the drawing of the broken ore be so regulated that its surface will be fairly even for any particular section of the stope. In other words, the drawing of broken ore starts from the chutes on the hanging-wall side and proceeds in regular order from chute to chute until the foot-wall is reached. The exact number of cars of ore to be drawn from the different chutes is determined from the stope-maps and the strict enforcement of this rule will prevent the loss of ore by reason of its becoming mixed with waste-rock.

As the stopes are emptied of broken ore and the pillars removed, the waste-rock will cave from the 'foot' and hanging wall. This material forms a mattress on the top of the broken ore and follows down as the broken ore is removed.

Since the cross-cuts are driven under one edge of the stopes, the chute-raises on one side hole through under the centre of the stope and on the other side into the bulldozing-chambers, which are placed in the pillars.

Manway-raises connecting the levels are put up from both the 'foot' and hanging-wall drifts opposite the centre of the stope-pillars. The manway-raises from the foot-wall drift are put up opposite the odd-numbered pillars and those from the hanging-wall drift opposite the even-numbered pillars.

At the first intermediate level, 25 ft. above the main level, the raises are connected with the 'foot' and hanging wall by cross-cuts driven through the centre of the stope-pillars. From these cross-cuts, short drifts are

run to connect with the back of the bulldozing-chambers, or to the adjoining stope. (See Fig. 3.) At intervals of 30 ft. in height, cross-cuts, called man-way cross-cuts, are run in the odd-numbered pillars from 'foot' to hanging wall. These cross-cuts are connected with the stopes by short drifts, for the purposes of communication and ventilation, as may be found necessary.

THIRD METHOD. This has been proposed for stoping blocks of ground composed in part of crushed black graphitic slate and in part of mixed schist and meta-gabbro or blocky meta-gabbro or schist.

It is proposed to start from a level at a depth of over 1000 ft. below the surface and under-cut blocks of ground 250 ft. wide and of a length corresponding to the width of the ore-zone (500 to 800 ft.); then by means of raises and short powder-drifts, similar to those used for blank-blasting in quarries, to blast down part of the back of the stope into a chamber previously excavated and cause the ore in the roof of the stope thus formed to cave. The ore broken and caved by the above method is to be drawn off through chutes on the main haulage-level, and the large slabs broken into pieces that will pass through the chutes, in the bulldozing-chambers placed along the sides and the foot-wall end of the stopes.

Fig. 7 is a projection at right angles to the strike of the vein and shows the most important features of this method of stoping. The orebody is divided into blocks

FIG. 3.

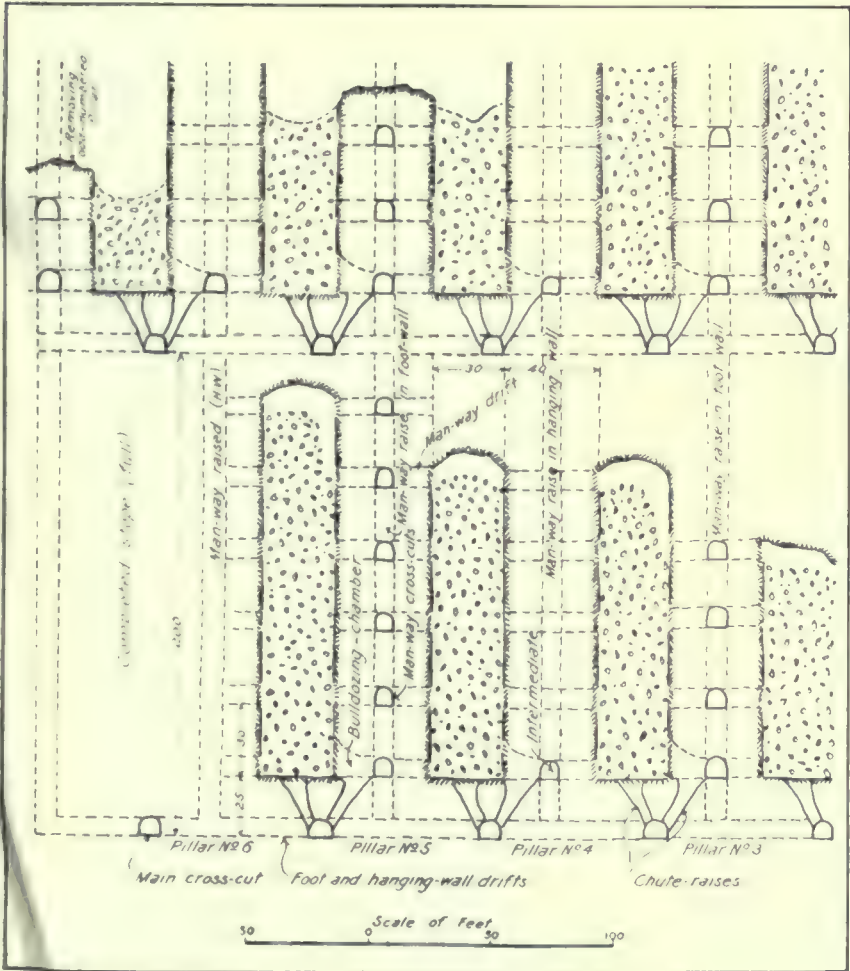

FIG. 4.

with level-intervals of 200 ft. Each level is connected with a main ventilating-raise, placed in the foot-wall ground and driven at an angle parallel with the dip of the foot-wall of the orebody.

The plan of opening the main haulage-level follows closely that described under the First Method, with the exception that the chute-raises will be closer together, for the reason that is is planned to draw all the ore broken in a number of the levels above the main haulage-level through one set of chutes and bulldozing-chambers on the main haulage-level. When the chute-raises have been completed and the chutes built, the sill-floor of the stope is cut out over the entire area of the proposed stope.* The height of the first cut will change with the character of the ground, varying from 7 to 60 ft. Since the bulldozing-chambers are to be placed along both sides and the foot-wall end of the stope, it seems that it will be necessary to either carry up the stopes by ordinary shrinkage methods to a height of 50 or 60 ft. or cut out the sides and foot-wall end of the stope to a similar height, leaving the centre of the stope low and unsupported.

After the stope has been cut out and the bulldozing-chambers completed it is proposed to put up a number of raises connecting the back of the stope with the bottom of the next higher level. At suitable intervals, varying from 20 to 30 ft., short stub or powder-drifts will be run from each stope-raise—these powder-drifts to vary from 10 to 30 ft. in length, depending on the character of the rock. The purpose of connecting the stope-raises with the next higher level is twofold: To furnish ventilation and to give access to the powder-drifts after stoping (bank-blasting) has been commenced.

The second period of stoping, namely, bank-blasting and caving, is started by drawing from the shrinkage portion of the stope as much of the broken ore as possible, thus leaving a large open chamber. Explosives are then lowered from the level above through the various stope-raises to the lowest row of powder-drifts. The explosives are then to be loaded into the powder-drifts, tamped and connected with electric detonators in the manner common to quarry bank-blasting. After the row of powder-drifts has been blasted and a suitable amount of the spoil drawn, the other rows of powder-drifts are handled successively in the same manner until the back of the stope reaches the next higher level.

It is to be observed that, after the second stage of stoping has once been started, the stopes will be impassable on account of the ragged and dangerous character of the roof and the only method of breaking pieces of rock too large to pass through the chutes is to have them flow by gravity to the bulldozing-chambers, where they can be block-holed or bulldozed. The angle at which broken ore in a stope will cease to flow depends to a great degree on two factors: first, the amount of moisture present and the amount of packing the broken ore has been subjected to, and second, the size, shape, and character of the pieces broken down from the roof. If the rock is dry and of such a character that it will crush into small uniform pieces, it will flow at a much flatter angle than a mass of broken rock made up of soft fine and large irregular slabs of hard tough rock. When shrinkage or caving methods are applied to wide stopes, much trouble is experienced in causing the broken ore to flow freely to the chutes and, where it is impossible to put men in the stope to loosen the packed ore by 'picking in' or blasting, there is often a loss of large quantities of broken ore or at least a delay in its recovery until the stopes from the next lower level are carried up and completed.

FOURTH METHOD. This is applicable to orebodies in black slate or in schistose meta-gabbro, similar to those in the hanging-wall portion of the Perseverance orebody above the No. 5 level and elsewhere in the Juneau ore-zone.

Ore of this character drills better than that in fissured meta-gabbro and has a tendency to break in long thin slabs well beyond the bottom of the holes. The broken ore, after exposure to air, will crumble and on its passage through the stopes to the chutes and bulldozing-chambers a large proportion of the larger pieces will be

so reduced in size that they will pass through the chute-openings, thus materially reducing the cost of bulldozing and sledging.

When the orebody is first opened, it stands fairly well for a time sufficient to safely cut out the sill-floor, but after stoping is started it has a tendency to cave from the hanging wall, thus confining most of the machine-drilling to the foot-wall portion of the stope.

The following description presupposes that the preliminary development work, such as shafts, ore-ways, and ventilating-raises, has been completed and the main cross-cut on the level run through the orebody to be stoped.

Fig. 8 and 9 show, in some detail, the method of opening up a block of ore preparatory to stoping, and Fig. 10 shows the manner of cutting out a stope, back-stoping the ore and the relation of the bulldozing-chamber to the broken ore in the stope.

When opening up a level the first thing done is to drive a cross-cut from the main ventilating-shaft to and through the orebody to be stoped. If possible this cross-cut should unite with a manway-raise connecting at least two levels and driven in the foot-wall of the orebody to be stoped. At the point where the above cross-cut intersects the foot-wall, drifts are turned off in opposite directions and continued along the foot-wall to the limits of the orebody. At intervals of about 400 ft. manway-raises are put up along the foot-wall to the next higher level, and stub-drifts run as explained under the First Method.

The spacing of these manway-raises is controlled by the length of the proposed stopes, as the manway-raises are put up along the centre line of the stope-pillars. As the levels are extended, the chute-raises are put up 25 ft. centres on the foot-wall side of the drift, under the proposed bulldozing-chambers to a height of about 30 ft. If the orebody is over 50 ft. wide, it is convenient to put up a line of chute-raises from the hanging-wall side of the level so that they will intersect the floor of the proposed stope at points about midway between the foot and hanging walls. These chute-raises are used primarily for drawing off the broken ore during the cutting-out of the stope and in the early stages of the back stoping before the hanging-wall portion of the stope is high enough to permit the broken ore to flow to the bulldozing-chambers.

At a distance of 30 ft. above the level, intermediate drifts are run in the foot-wall waste parallel with and about 40 ft. from the orebody. They are connected to the bulldozing-chambers by two cross-cuts. The idea of two cross-cuts is to improve the ventilation and means of communication. On account of the draft being up through the bulldozing-chambers into the stope, the first bulldozing-chambers were cut out so that the intermediate drifts simply connected the ends of the chambers. This construction was changed to the one illustrated in Fig. 8 on account of a number of accidents caused by the broken ore hanging up in the stopes and leaving large open spaces. These open spaces, together

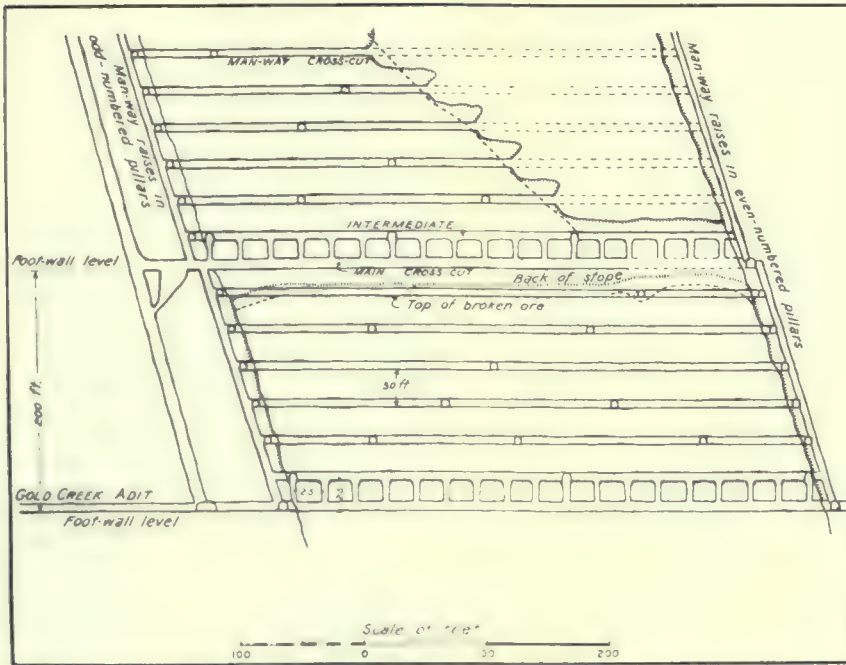

FIG. 5.

with the bulldozing-chambers, would be suddenly filled by a rush of broken ore when the 'hang up' lets go, thus not only subjecting the men working in the bulldozing-chambers to great personal danger, but often cutting off their means of ingress and egress by reason of the manways being filled with broken ore. The intermediate drifts are connected with the manway-raises by means of short cross-cuts or inclined raises.

The stopes are cut out as indicated in Fig. 10. It will be noted that on this sketch the bottom of the stopes has been cut out at an angle of 45° . In the past this has only been done in a few instances, the majority of the stopes being cut out with a horizontal floor. The objection to the 45° floor is that it leaves a large block of ore between the level and the bottom of the stope that will have to remain until the stopes from the next lower level reach it. However, with a 45° bottom, a large expense

chute-raises and driven upward and toward the hanging wall at an angle of about 50° . As these cross-cuts progress, they are carefully sampled and the limits of the ore

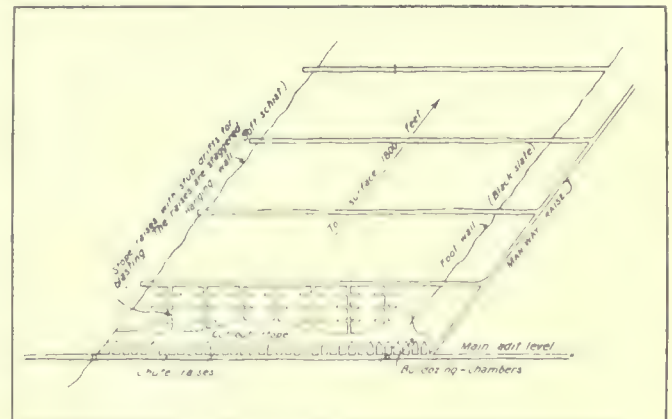

FIG. 7.

accurately determined. The bottoms of these cross-cuts are driven to correspond with the bottoms of the future stopes and the cutting out of the floors of the stopes is performed by simply drilling and blasting from the sides of the cross-cuts until they meet and form the floor of an open chamber.

The stope, however, is not cut out to the limits of pay-ore as determined from the stope cross-cuts, but a width of ore is left next to the hanging-wall side. The thickness of this ore varies according to the nature of the ground, from 10 to 30 ft. The object of leaving this layer is to prevent dilution of the stoped ore by waste caving from the hanging wall. All of the ore so left is not lost, for, in practice, most of it caves and becomes mixed with the stoped ore before the stope is drawn. It requires experience and an intimate knowledge of the mine to determine how wide this pillar should be. If it is

FIG. 6.

not wide enough, the caving will extend into the waste-rock of the hanging wall and will become mixed with the broken ore; if the pillar is left too wide, ore will be left as the stope progresses and will be lost.

The black slate and schistose meta-gabbro drill well and permit of the use of one-man hammer-drills. Long holes can be drilled and, since the average footage per machine-drill shift is about 80 ft., the tons broken per drill-shift are correspondingly high.

As little bulldozing and sledging as possible is done in the stopes, but the large slabs and pieces of broken ore are allowed to work down to the bulldozing-chambers, where they can be safely and economically handled.

When the stope reaches the next higher level, it is continued until the block of ore left between the level and the bottom of the stope is extracted. The connection between the top of one stope and the bottom of the next higher one is made in practically the same manner as in the First Method.

About 35% of the broken ore can be drawn as the work progresses and this ore, as well as the broken ore contained in the finished stope, is drawn through chute-raises equipped with 6-ft. arc-gates, loaded into cars and trammed to the transfer-raise to be again loaded into cars and hauled to the coarse-crushing plant at the mill.

TRAMMING. In the majority of mines, where large tonnages are handled, the cost of tramping includes the loading of the broken ore into cars, from chutes or otherwise, hauling the ore or waste to the shaft-pockets or transfer-raises, dumping the loaded cars, and returning the empty cars to the point of loading. It is, therefore, apparent that the methods and means employed for each stage of the operation have a direct bearing on the amount of material that can be handled in a given time and also on the final cost of the operation.

CHUTES. In small mines, where the ore is blasted down on timbered floors and there broken into comparatively small pieces, the design of the chute is not of great importance and the ordinary board-chute is satisfactory, both from the standpoint of efficiency and cost. In the large low-grade mines of the Juneau belt, where the ore is broken in chambers devoid of timber and where every effort is devoted to the quick and cheap delivery of enormous tonnages of rock, the design of the chute becomes of prime importance.

The coarse-crushing plants now built have machines with openings large enough to receive pieces of rock 36 by 48 inches. It is, therefore, apparent that the chutes will have to be so designed that they will handle this material quickly and continuously.

For the diorite ores of Douglas island, where the broken rock is dry and has a large proportion of coarse material, the so called finger-chute is in use and has been found to answer all requirements. Experience has shown that when the number of fingers in a chute is increased to more than six, there is a tendency for the outside ones to lap over the side-boards and jam. This limits the width of the chute to 42 inches, allowing pieces of rock 24 by 36 in. to be handled with ease. With the

introduction of larger crushers and the increased use of transfer-chutes, where it is necessary to handle large tonnages in a limited time, the finger-chute is inadequate and has to a large extent been superseded by an arc chute-gate, both on Douglas island and in the mines on the mainland. In the Perseverance mine, of the Alaska Gold Mines Co., a small bulldozing-chamber with a grizzly-floor, made of 80-lb. rail, is placed immediately over the head block of the chute. This type of chute was originally used by G. T. Jackson, when superintendent of the Perseverance mine.

The three most important features of this type of chute-gate are:

1. Simplicity of operation, one man only being required to operate the chute.
2. Capacity.
3. Freedom from overflow or spilling of fine on the track.

The chute is operated by one man standing on the platform. The weight of the arc-gate is counter-balanced by a counter-weight, thus leaving only the friction of the broken rock to be overcome when opening or shutting the gate, which operation is performed by lowering or raising the handle.

At the transfer-chutes in the Treadwell mine, the arc-gates are eight feet long. A train of 10-ton cars is loaded by hauling the train slowly underneath the opening of the chute, it being unnecessary to stop the train and spot each car as is the case when using the finger-chute.

It will be noticed that the chute is so designed that either the $\frac{1}{4}$ -in. steel lining or the first layer of 2-in. plank forming the floor of the chute is practically in contact with the inside of the arc-gate, whether it is open or shut. This prevents the fine material sifting out and falling on the tracks and also prevents the jamming of the gate by reason of pieces of rock becoming wedged between the lining of the chute and the arc-gate. Since the chute is closed by raising the gate through the stream of broken ore, it will stop the flow quickly and cleanly even though very coarse material is being handled.

When operating either the common board-chute or the finger-chute, a great many accidents occur to chute-men by reason of rocks bounding from the chute or falling from the cars being loaded. With both of the above types, the chute-men when loading cars work either directly in front of or slightly to one side of the chute-opening and in line with any material falling from it. When operating the arc-gate they stand on a platform above the cars and are thus protected from objects falling from the chute or from cars.

CARS. In mines where there is a big tonnage to be handled, there is a marked tendency to use cars of large capacity. This is particularly true in the Juneau district, where, since most of the development work is in ore that stands well, the drifts and cross-cuts are unusually large.

For development work, a specially designed low-

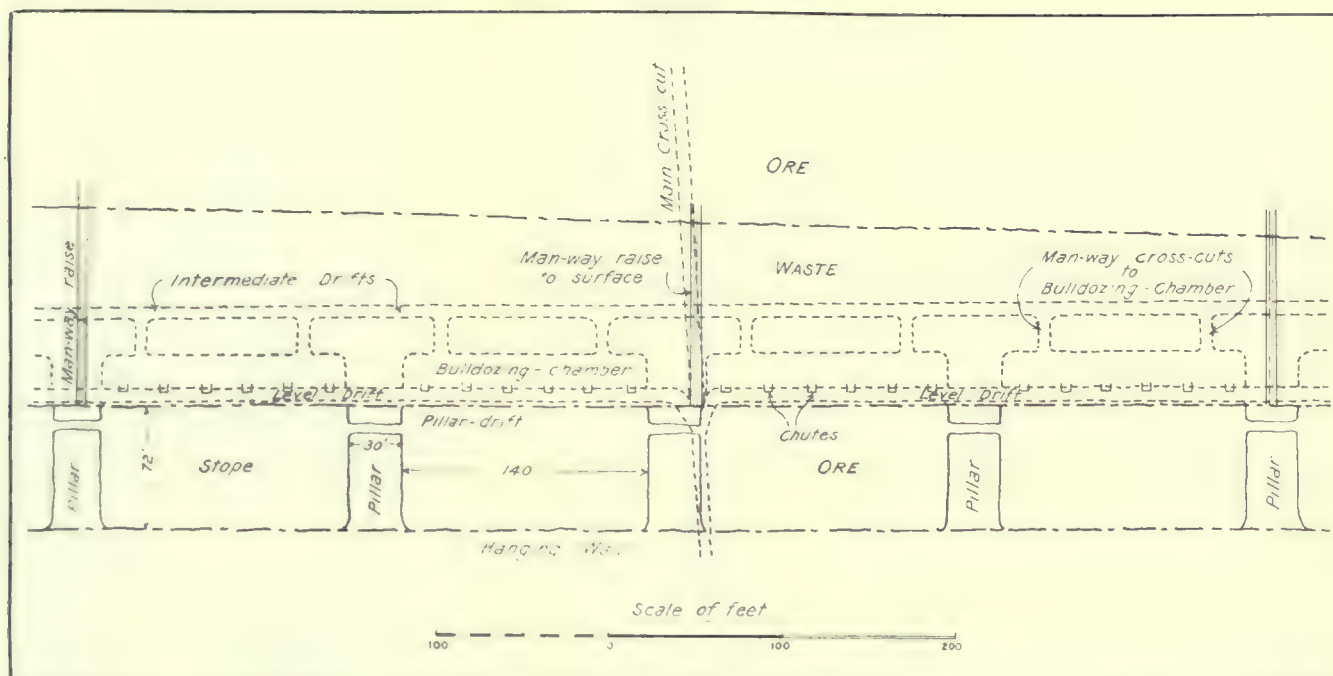

FIG. 8.

shoveling car, holding about two tons, is used. If the work is near the 'ore' or waste-way, the cars are trammed and dumped by the shovelers; if the working-place is at a distance from the dumping-place, the cars are trammed to the nearest side-track and then left to be collected and hauled to the dumping-place by a special crew. (Fig. 12 shows the type of car now being used on Douglas island and in some of the mainland mines). Since these cars hold from 10 to 12 tons of ore, the tramping is done by mechanical haulage. The type of car illustrated is used either singly or in trains to haul the ore from the stope-chutes to the ore-pockets, and they have shown a marked saving per ton of ore trammed over the two and three-ton cars heretofore used.

The first cost of this type of side-dump car is much higher than a car of equal capacity designed to be dumped by means of a tippie, but when the first cost of the tippie, including driving mechanism and power-connections, and its cost of operation are taken into consideration, it will work out the cheapest per ton of rock trammed. Since the opening is practically the entire side of the car and the gable-ends are steep enough to prevent the fine hanging up, these cars are capable of handling both fine and coarse material.

When these cars are used in trains, a sheet-steel apron is attached to one car and extended to a sufficient distance to overlap the top of the adjoining car preventing rock from falling between the cars and blocking the track when the train is being loaded.

In the Perseverance mine of the Alaska Gold Mines Co. the so-called Granby system

of tramping is used. The cars have side-openings and are self-dumping. The capacity of the cars is only limited by the size of the underground openings and the structural difficulties and cost of building large cars. The most economical size of car for underground tramping is about 100 cu. ft. The cars are made up in trains of from six to ten cars and are emptied automatically by hauling the train past a simple stationary dumping device. It is not necessary to uncouple the locomotive from the train nor is there any attendance required. The

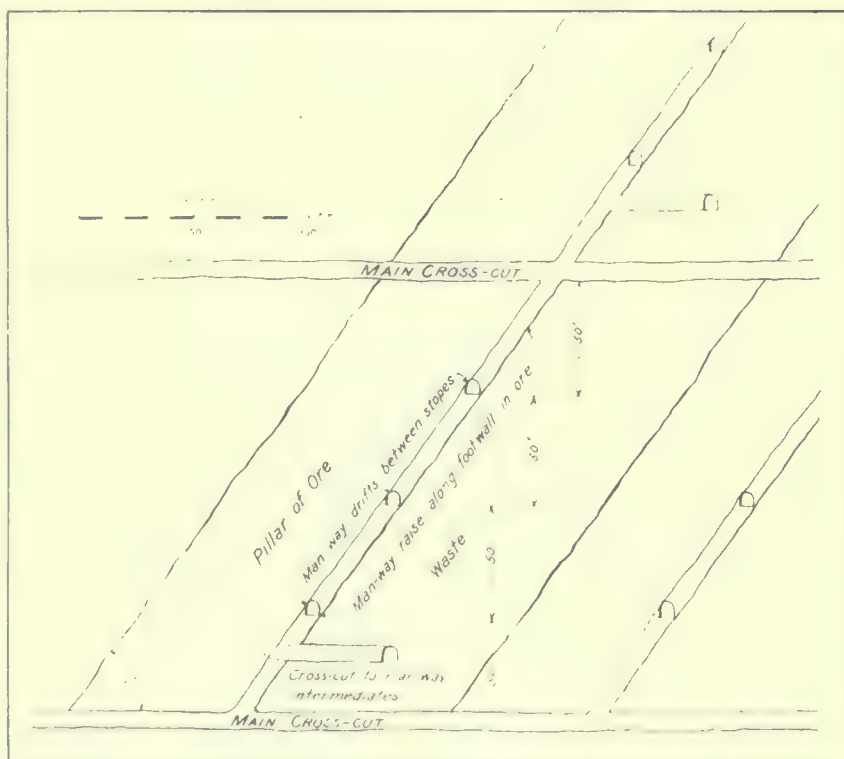

FIG. 9.

wear and tear on the cars is small and the system is more economical and satisfactory than any other so far used or suggested for the large low-grade mines adjacent to Juneau.

HAULAGE. At the present time, there are five different methods of hauling cars underground.

1. Hand-tramming, where one or more men push the cars to and from the place of use.

2. Animals; both horses and mules are employed.

3. Endless rope; this method is used in the mines of the Treadwell group to increase the tonnage over that possible by means of men or draft-animals.

4. Storage-battery locomotives; the cars being gathered, either singly or in trains, and hauled to any desired point on the level.

5. Electric-trolley locomotives; the tramming is done by electric locomotives deriving their power by means of a trolley from bare wire strung throughout the route to be traversed.

The advantages and disadvantages of the first three types of tramming are well known. Where the distances are short, the question of capacity determines the choice of methods, the cost per ton being practically the same where the method selected fits the job. To my mind, the most important item that has been contributed, in the last few years, toward the reduction of tramming-costs has been the perfecting and introduction of the storage-battery locomotive. These engines, for underground service, are now supplied by a number of manufacturers in sizes ranging from 3 to 10 tons, and their continuity of service and cost of operation have been most satisfactory. I feel confident that it will be but a comparatively short time before they will have supplanted all other methods of tramming in large mines where the distances are not too great. Where the hauls are long, the trolley-locomotive still holds its place, but for a variety of reasons (such as safety, mobility, etc.) the storage-battery locomotive will take the place of the trolley-locomotive.

If continuous service is required of the storage-battery locomotive, duplicate sets of batteries are supplied. These are furnished with racks that hold the necessary cells for the locomotive and they are so arranged that the discharged cells can be quickly removed and charged cells substituted. The charging-stations are usually placed at or near the main ventilating-raise or shaft and do not require any additional labor or skilled attendance.

In a number of mines, gasoline-locomotives have been tried, but their performance has not been satisfactory. When the machines are new and the temperature not too low, they do fairly well, but they require careful handling and, if the ventilation is at all poor, they are dangerous on account of the noxious gases they generate.

SAMPLING AND ASSAYING. On Douglas island, where the ore is a homogeneous diorite and the gold-content in any particular part of the mine is evenly distributed, the determining of the value of the ore is a comparatively simple operation. The ore is usually sampled in five-foot sections by moiling a groove at right angles to

the strike of the deposit, four inches wide by from one-half to one inch deep. All the material thus obtained is sent to the assay-office and ground to pass an 80-mesh screen. It is then cut down and assayed in the usual manner. This procedure gives results that will check. The gold-content of large blocks of ore, determined as above, agrees closely with the mill-returns plus tailing.

When we come to the large orebodies of mixed quartz, slate, and meta-gabbro on the mainland, the problem of determining their gold-content becomes difficult. In the first place, the ground is much broken and disturbed by slips and faults, making it necessary to take a great number of samples to determine the value of even small blocks of ore. The gold is coarse and is contained in the quartz lenses or stringers. In the slate orebodies the quartz stringers are fairly distinct, while in the meta-gabbro orebodies they vary from lenses 20 ft. wide, at their widest, to a stock-work of minute interlacing stringers. Where the quartz stringers are absent or sparsely distributed, whether in slate or meta-gabbro, the rock is not rich enough to be mined.

As a result of long experience with such ores and after trying many methods of sampling and assaying with many thousand samples, I have come to the conclusion that the ordinary methods of hand-sampling do not give results that can be depended upon when estimating the gold-content of any large mass of ore. The method of hand-sampling that has given the best results is the one proposed by W. W. Mein. This method has been checked by mill-tests and when the samples were carefully taken and the assaying properly done, they agreed within acceptable limits. The essential difference between this method of sampling and that employed in the Douglas island mines is that in place of the length of the sample-section being confined to a predetermined number of feet, its length is governed by the width of the particular stringer of quartz or band of rock to be sampled. If the width is more than five feet, a sufficient number of samples was taken to insure that no one sample would have a greater length than five feet. It often happens that a six-inch stringer of quartz assaying, say, \$750 per ton would have ten feet of barren black slate on each side of it. If the ground were sampled in 5 or 10-ft. sections, the average obtained would be misleading. In the meta-gabbro ore a distinction is made between stringers over, say, three inches wide, and the mineralized meta-gabbro, they being sampled separately.

The most satisfactory method of determining the gold-content of the above ores is by the use of a test-mill capable of treating a comparatively large tonnage of ore. The material to be tested can be obtained by slabbing off a section, say, two feet thick, over the entire side or top of the level, depending on whether it is a cross-cut or drift, or the ore can be stoped from any desired portion of the mine.

The unreliability of hand-sampling has been fully recognized in the district, and, as a result, all of the mines that are now producing or being developed on a large scale have been or are now equipped with experi-

FIG. 10.

mental or sampling mills. The Alaska Gastineau and the Alaska Juneau companies have treated large tonnages of ore from different portions of their mines before the experimental mills were built preparatory to the construction of their permanent plants. A careful sampling, by means of a 5-stamp amalgamating and concentrating mill, was carried out at the Ebner mine. This work has been briefly described by Sidney Jennings, under whose direction it was performed. It was done with great care and attention to detail and I am satisfied that, if this method of determining the gold-content of the ore is adopted in the district, it will give accurate information as to the value of the various orebodies.

At the Perseverance mine a 100-stamp mill was first used to sample the ore from the mine and during its operation it treated about 300,000 tons of ore. This was the first time that a large tonnage of unsorted ore, from the mainland mines near Juneau, was thoroughly sampled. It was also in this mill that the first comprehensive re-grinding and concentrating tests were made. The

result of this work was far-reaching, for when the Alaska Gold Mines Co. constructed the experimental mill in Sheep Creek basin, it differed from all the mills previously built in the district, free-gold amalgamation being eliminated and a straight concentration and re-grinding method substituted. It was the sampling data collected in the Sheep Creek experimental mill that determined the final flow-sheets for the large Alaska Gastineau and Juneau mills.

No matter how carefully the sample is taken, the final results will be worthless unless the assaying is done properly. To get assays that will check, it is necessary to grind the pulp so that it will all pass through at least a 150-mesh screen. On account of the coarse gold in the ore, close watch should be kept for 'metallics'; their value should be determined and added to that of the pulp in the usual way. The ore is not a difficult one to assay and I am sure that if the pulp to be assayed is ground fine enough, the assay results will check, and confidence

as to the results will take the place of the uncertainty that has existed in the past.

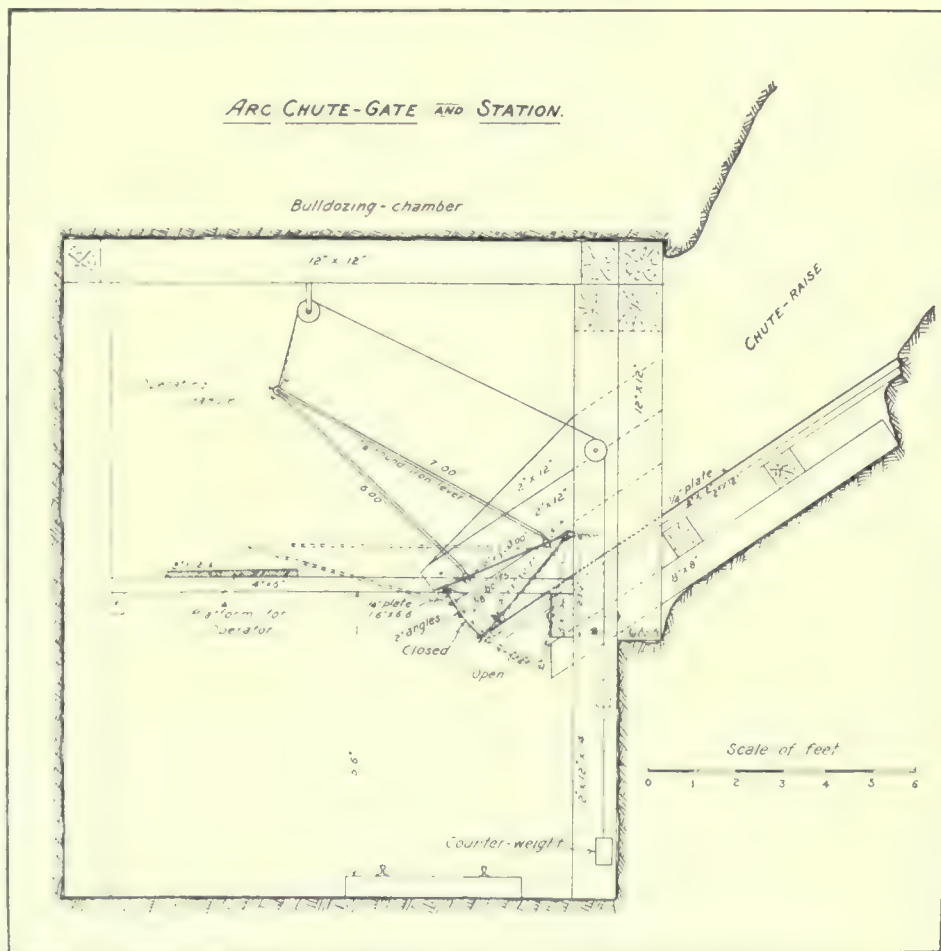

FIG. 11.

An Improved System of Classification

By JAMES M. HYDE

Flotation concentration, meritorious as that process has proved to be, is not a panacea for all of the troubles encountered in the treatment of ores. There may be some ores requiring such fine grinding to free their valuable constituents that flotation may be a logical single process for their treatment. Such ores do not appear to be common.

From the standpoint of the smelter it is highly desirable that a minimum amount of fine concentrate be made, as this product tends to make flue-dust, with corresponding furnace-losses. It may be necessary therefore for the smelters to pay less for the finest concentrates than they can afford to pay for coarser material of the same chemical analysis.

Many ores have their metalliferous constituents so distributed that without crushing finely a considerable proportion of gangue can be discarded. Tabling and jigging are cheaper methods of treating material of the sizes to which they are adapted than flotation is ever likely to be.

In the treatment of complex sulphides, where it is desirable to make different concentrates instead of one general sulphide concentrate, it is best that a minimum of fine be produced. By tables and jigs lead may be easily separated out from many ores as a high-grade concentrate, and where a supplementary process is needed for separating minerals of like specific gravity, as, for instance, pyrite and the copper minerals from zinc-blende, the best results either by electro-static or electro-magnetic separation are obtained in treating materials too coarse to be readily floated.

It is highly probable that selective flotation will some day be so perfectly worked out that by flotation concentration alone a mixed sulphide ore may be divided into fairly high-grade concentrates of two or even three classes. From an ore containing pyrite, chalcopyrite, blende, and galena it is probable that we shall soon be able to make, by selective flotation, a lead concentrate low in copper and zinc, a copper concentrate low in lead and zinc, and a zinc concentrate low in copper and lead.

Even when that ideal is accomplished we cannot expect flotation to become the sole means for concentrating such ores, as the reasons previously mentioned will still make it desirable to remove as much of the metalliferous minerals as possible in sizes too coarse for flotation, to throw away as much of the tailing as possible without fine grinding, and to send to the smelter a minimum amount of 'slime concentrate.'

The perfection of electro-chemical and hydro-metallurgical processes for recovering the several metals from

concentrates may render it advisable to use flotation as a sole concentration method in the treatment of ores in the milling of which a combination of methods is now necessary, but at the present time, and probably for some time to come, the mill-man must look upon flotation as a valuable auxiliary process and adapt his operations to the end of making it serve his needs in the most efficient manner.

Ore-dressing had its beginning in crude operations, but it is gradually developing into a highly specialized art. Its perfection lies largely in the bringing of all of its operations under the most positive and intelligent control.

In introducing flotation concentration into mills that were built and in operation before the adoption of this process, the greatest obstacle I have had to overcome has been the difficulty of getting all of that part of the ore which it is desirable to treat by the new process gathered together and delivered to the flotation-machine at the right consistence.

The feed to the flotation-machine usually consists of the finest part of the ore resulting from the primary crushing operations and the re-ground middling or tailing from the jigs or tables. These products are derived from classification, jigging, and tabling operations, which, as a rule, produce a very dilute pulp.

The first mill in which I introduced flotation, the one at Basin, Montana, at that time rented and operated by the Butte & Superior Co. of Butte, was following the practice of jigging the whole of the ore after it had been crushed to pass through a 5-mm. screen without any preliminary classification. The launders ahead of the jigs were so flat that extra water had to be added to the pulp to keep it flowing. The jig-tailing was classified and the coarser portion was re-ground and again classified. The resultant products were divided between jigs, tables, and vanners for further treatment.

When the fine from the classifier-overflow and the tailing from the tables treating the finer sand and from the vanners were gathered together they formed a pulp containing over 50 parts of water to 1 part of ore. This pulp was thickened in cones and the overflow from these cones was found to carry into the tailing as high as 15% of the metal in the ore. The fine ore overflowing from the cones used to thicken the primary classifier-overflow contained a higher percentage of metal than was contained in the crude ore. These conditions obtained when the mill was treating 400 tons of ore per day, and using, if I remember correctly, 70 standard cones for pulp-thickening.

The ore being treated in this mill carried from 18 to

23% of zinc as sphalerite, 1 to 1½% of lead as galena, small amounts of pyrite, a few ounces of silver, and a little gold in a gangue consisting principally of quartz, rhodonite, rhodochrosite, and granite in which part of the feldspar was kaolinized.

The peculiar difficulties encountered in the treatment of this ore were due to the fact that the kaolinized feldspar made a slime that settled very slowly; the crush-

old mill, but the same difficulty was experienced in getting all of the fine portion of the pulp gathered together and delivered to the flotation-machine in proper condition for treatment. Four large flat-bottomed thickening-tanks with rake-arms for gathering the settled slime to a central discharge were used in preparing the dilute classifier-overflow. Lime and ferrous sulphate were added as coagulants, but the dilution of the pulp was

FIG. 1. DESLIMING MACHINE.

ing necessary to bring the ore to 5 mm. size broke much of the sphalerite into sizes too fine to catch by tables or vanners; and when a commercial grade of concentrate was maintained the jig and table tailings contained much sphalerite that could only be released from the quartz in which it was enclosed by grinding to such a degree of fineness that the sphalerite thus broken free could not be efficiently recovered by tables or vanners.

In a mill built later to treat this same ore the dilution of the slime throughout the plant was less than in the

such that the total volume to be treated was so great that again it was found that as much as 15% of the valuable content of the ore would sometimes be carried to waste in the overflow from the pulp-thickeners. This was particularly exasperating as the flotation department could make high-grade concentrate and an excellent recovery from this material if delivered to it in proper condition.

The 'slime' portion of this ore was of an extremely slow-settling type, as shown by the fact that when a Callow cone was filled with the pulp and thrown out of

circuit and permitted to stand at rest for three hours, the whole pulp was still extremely opaque and the material in suspension still contained 14% of zinc. A large equipment of cones and flat-bottomed thickeners was installed before all of the flotation-feed could be put into proper condition for treatment.

The obvious deduction from a study of the behavior of this and similar ores was that the ideal way to overcome the difficulty of dealing with pulps too dilute for satisfactory treatment would be to avoid the production of them. Preventive rather than curative methods were indicated. I was led at that time to the belief that it should be possible to invent a thoroughly satisfactory system of classification, which would in one operation, immediately following each crushing, remove all of the material of a desired degree of fineness with an absolutely minimum dilution and then turn the sand over to a classifier, which would classify it and deliver a slimeless product to tables or jigs, so that a simple dewatering operation would prepare the table middling or tailing for re-grinding, and the water removed before re-grinding would be so free from valuable mineral that it could be thrown to waste, or returned to the mill water-supply.

The ordinary system of hydraulic classification permits such mixing of 'slime' with the sand from each spigot of a hydraulic classifier as to cause slime to be a constituent of the tailing of each of the machines treating the sand-sizes. The true 'slime' product of the hydraulic classifier is diluted with the hydraulic water added in each of the compartments, and carries therewith the bulk of the water contained in the pulp before classification, all combined into an excessively dilute pulp. My experience with drag-classifiers has proved them to be useful and logical as a means of removing much of the slime previous to other classification, but I have not found them sufficiently positive to remove the slime so completely that the back-water from the tables could be kept so free from valuable metal that it could be discarded without separation and thickening.

The most logical method of applying known physical principles to this problem seemed to be to combine hydraulic classification, in which only so much water would be added to the pulp as is necessary to keep in suspension all of the material desirable to retain in the slime-pulp, with a means for removing the sand from below the hydraulic column through which they have settled without setting up any downward current of water such as would tend to carry some slime along with the sand. A combination of a hydraulic classifier and a drag-classifier promised to fulfill the necessary conditions and to render possible a complete separation of slime from sand, and also to establish complete control of pulp-dilution throughout the entire mill. This should give closer control of all concentration operations and avoid the expense and nuisance of pulp-thickening devices and the losses occasioned by the escape of metal in pulp-thickening overflows.

Several years ago I began to work out the details of a

machine that would accomplish this desired result. In the summer of 1915 I built a machine consisting of a combination of a cone-classifier and dewaterer. This was ready to start when a somewhat similar machine was described in the MINING AND SCIENTIFIC PRESS, which description was followed by a number of contributions showing that other engineers were working on the same problem.

In the summer of 1916 I built and installed in the Kittimaec mill, near Silverton, Colorado, an improved machine of this type in which more perfect hydraulic classification was accomplished by so proportioning the sorting-column and arranging the sorting jets that the tendency for some mingling of the 'slime' with the sand by counter-currents was overcome. To make the machine still more positive, I have designed a revolving shutter, on the principle of the revolving doors used at the entrances to buildings, and placed this below the sorting-column so that all possibility of downward water-currents is shut off while the classification is made continuous.

The machine consists essentially of a hydraulic classifier, from beneath the hydraulic column of which the sand passes into a drag-classifier dewaterer. By varying the volume of hydraulic water used, the control of what will be thrown into the overflow product is very positive. The completely deslimed sand is delivered in a practically dewatered condition ready for division into parts best suited for the table to which it is to be sent, or ready to return to the ball-mill or tube-mill, if complete fine grinding is to be followed.

One of the most striking merits of the ball-mill as a substitute for grinding apparatus in which the pulp is discharged through screens is that the ball-mill does its best work with so small an amount of water that the removal of the finished product with all of the water used in the ball-mill plus the water necessary for desliming yields a pulp of minimum dilution.

The ore in this plant is crushed to 1½ inch size by rock-breakers at the mine and is delivered to the mill-bins by an aerial tramway. From the bins it is fed by a traveling-belt feeder to a ball-mill and ground to a practically finished product. The ball-mill discharge goes to a trommel, which returns a small amount of oversize. The undersize from the trommel goes to the drag-classifier, the fine product of which is taken off as a pulp so thick that the superintendent has found it advisable to dilute it with clear water before treating it in my improved flotation-machines, which are also part of the equipment of this mill. The ideal condition is satisfactorily attained, so that no pulp-thickening devices are needed in the preparation of the flotation-feed. The tables that are served with the sand coming from this deslimer divided into proper sizes by the rotary classifier, later to be described, have no slime in the back-water.

Where tables are to be used in treating the sand sizes, the sand-product of the fine-classifier is discharged with the addition of barely enough water to carry it through

a steeply inclined launder into the circular feed-pan of the rotary classifier.

The principle of classification made use of in this rotary classifier can be easily demonstrated. Take a portion of ore-pulp and wash it free from slime by repeated agitations and decantations. Into a burette, or a larger tube, closed at one end, introduce a few grams of washed sand and fill the tube with water. Put a depth of two or three inches of water in a pan. Close the pipe with a finger and invert it, submerging the open end in the water in the pan before removing the finger from the end of the tube. As the sand settles describe a circle

if the plaque is carefully removed from the water, and much valuable information may be obtained as to the distribution of the constituent minerals in the various screen-sizes and the extent to which the minerals in the different sizes are broken free from each other.

The sand-classifier consists essentially of an upper rectangular tank in which is suspended a submerged series of vertical channels radially disposed around a revolving vertical shaft, the channels revolving above a series of pockets with independent discharge-spigots. The vertical shaft is revolved by a differential-speed mechanism by which its speed can be closely regulated. The free-settling ratio of mineral particles in water is utilized for classification. The classifier is filled with water to above the top of the vertical channels, of which there are 60 in the machine as now used. The pulp is introduced continuously from a slot in the rotary feed-

FIG. 2. ROTARY SAND-CLASSIFIER, SECTION.

slowly with the tube near the edge of the pan, so that all of the sand will be allowed to settle in making one revolution. The sand will be found to be graded from the coarsest to the finest. If this circle is divided into eighths, the sand in the segments will correspond to the sand obtained in the corresponding pockets of the rotary classifier.

I have found this laboratory method of sand classification useful in examining unsized pulp and portions of the sizes obtained in screen-analyses. If the operation is performed over a vaning-plaque submerged in a pan of water, the sand can be examined with a glass,

Section through AB

FIG. 3. ROTARY SAND-CLASSIFIER, PLAN.

pan at any desired point. At a speed of two revolutions per minute each of the revolving channels receives pulp for but one-half of one second, so all of the ore-particles have a practically even start in settling. The machine is so timed by an adjustable differential-speed mechanism that the last fine sand settles before the first coarse sand of a subsequent lot reaches the bottom of the channel. Thus there is a gradation of sand from coarsest to finest in the pockets and a different product may be drawn off from each of the spigots. The product of each spigot may be sent to a separate concentrating device or the discharge from any number of spigots may be combined to constitute the feed for a single machine.

In the Kittimac mill, near Silverton, Colorado, where these classifiers are being used in the treatment of a mixed sulphide ore, it is found desirable to give the discharge from the first coarse spigot to a single table, that

from the second spigot to a single table, that from the third and fourth spigots to another table, and that from the remaining spigots to a fourth table. In order to facilitate this mixing of the products, a shallow box containing eight pockets is hung below the rotary classifier, each pocket having connection with the adjoining ones through holes in the partitions separating them, these holes having plugs that may be removed as desired. Each compartment has an independent pipe-discharge from which it may be drained to the table selected to receive its product. The combining of products of different spigots with the use of nothing more than short lengths of hose is thus made simple.

The rotary classifier receives a perfectly deslimed and practically dewatered feed from which substantially all of the sand of a given fineness and all of the colloid material has been removed. The water necessary to supply the spigots so as to carry the sand through the launders to the tables, and to insure a constant water-level by giving a steady overflow, is supplied through one pipe.

The sand classification performed by this machine is apparently as satisfactory as can be desired and the tables treating its sand-products give a close cut between the different minerals and run so uniformly that the cutters frequently do not have to be re-set for hours at a time.

I am informed that a crude attempt was at one time made to make use of this principle of classification, but that it met with failure, as the essential conditions necessary to success were not complied with. Among the conditions essential to the attainment of success are the following:

The sand must be completely deslimed before introduction into the free-settling classifier; the number of sorting channels must be so great that in the period of revolution found necessary, each channel must be under the feed-spout for so short a period that practically all of the sand received by it shall have an even start in settling; the depth of the channels must be sufficiently great to permit of the distribution of the sand received at one time over a circle of such radius as to cover probably not less than eight discharge-pockets; means must be provided for regulating the speed of rotation so that the finest sand will all fall out of the channel before the coarsest sand of a subsequent charge shall reach its bottom; clear water must be provided in sufficient quantity to supply each of the spigots with enough water to carry its discharge to the desired point, and to afford a slight excess for an overflow to maintain a constant water-level in the classifier; and valves should be provided so that the amount of water discharging with each spigot product may be closely regulated. The use of a rotary circular feed-pan with one discharge-point permits of an independent regulation of the point at which the rotating sorting-columns shall receive the sand.

I believe that the classification made possible by the use of these two devices furnishes such a positive control of milling operations as has never before been obtainable.

Alaskan Semi-Centennial

Commenting on the semi-centennial of Alaska under the American flag, Secretary Lane estimates that the land for which we paid \$7,200,000 in 1867 has brought more than \$750,000,000 into the channels of American trade. This item shines out like a candle in the gloom of national thriftlessness, to which our attention is so regularly directed. After the \$500,000,000 which we throw away annually by our prejudice in favor of cow's butter as against peanut butter; after the \$250,000,000 which we lose annually in productive human lives by refusing to keep trespassers off the railroad rights of way; after the \$365,000,000 which we could have, but do not, by introducing business methods into the Federal Government; after the half-billion dollars annually thrown away in the form of food values in skimmed milk; after the vast sums the farmers squander in their prejudice against decent roads; after ever so many other uneconomic factors which make it a puzzle how this nation has managed to keep out of the poor-house, it is a comfort to think of at least one investment that shows forethought and thrift. Perhaps it is the enormous profit we have realized on Alaska that has served to keep this country going.—N. Y. *Evening Post*.

Reactions of Sulphate-Solutions on Oil

It was suggested long ago in the Russian oil-fields that hydrocarbons are able to reduce sulphates to sulphides, and that they themselves are simultaneously oxidized to carbon di-oxide or to carbonates. Some of the sulphide formed in the reaction between the hydrocarbons and the sulphate-waters is undoubtedly oxidized to sulphur. Some of this sulphur is taken up again by the oil, which makes the oil heavier and more asphaltic. In the oil-fields of the San Joaquin valley the oil that has been most exposed to the action of the water generally contains the most sulphur, and is of the highest gravity. It seems probable that natural gas is also affected by these reactions, and that some of the carbon di-oxide formed is not taken up by the waters but mixes with the gas and lowers its heating value. The gas nearest the outcrop of the oil sands, where sulphate waters can most readily enter the strata, and where the reaction would naturally be most vigorous, may contain as much as 35% of carbon di-oxide. A preliminary report on Californian oil-field waters, containing a number of analyses and a discussion of the principles that control the chemical variations in the waters, has been issued by the U. S. Geological Survey as Bulletin 653, prepared by G. Sherburne Rogers, entitled 'Chemical relations of the oil-field waters in San Joaquin valley, California.'

COPPER production from the mines of the Chile Copper Co. amounted to 8,714,000 lb. in March, making a total for the first quarter of this year of 20,770,000 pounds.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

TREADWELL, ALASKA

DISASTROUS CAVING OF THE ALASKA TREADWELL WORKINGS.—
GASTINEAU CHANNEL FLOODS THE GREAT MINES.

On Saturday at midnight, April 21, the ground lying between the main openings of the Alaska Treadwell mines and Gastineau channel settled along the plane of a fault that extends out underneath the channel, and the salt water of the strait quickly poured into the extensive underground workings of the Alaska Treadwell, Alaska United, and Alaska Mexican mines. The disaster did not come without warning, for there has been observed for many months a noticeable subsidence of the surface above the mine workings, and various plans had been considered to remove as much of the ore as possible so long as it continued to be safe to do so, but it was recognized that an eventual collapse was inevitable, though it came somewhat sooner than had been anticipated. The subsidence was being watched carefully and as evidences were unmistakable that a cave was imminent the men were hoisted to the surface and no lives were lost, but a number of horses and mules employed in tramping on the lower levels had to be sacrificed, as there was not sufficient time to save them. The engineers of the company believe that work can be continued and levels opened far below the bottom of the flooded workings, by using the shaft of the Ready Bullion mine. This shaft had been connected with the main workings that are now flooded, but realizing the danger of just such a catastrophe as has occurred, a heavy bulkhead was built in the long drift of the 1350-ft. level that formed the connection between the Ready Bullion and the Alaska Mexican workings. At last reports the bulkhead had exhibited no sign of weakness, and it is hoped it will hold.

Messrs. R. G. Wayland, general superintendent of the Alaska Treadwell group, P. R. Bradley, consulting engineer, and J. H. Mackenzie, who is visiting at Juneau, are in consultation at Treadwell.

LEADVILLE, COLORADO

IMPORTANT DEVELOPMENT IN THE DOWN TOWN AREA.—POVERTY
FLAT TO BE EXPLORED AT GREATER DEPTH.—ACTIVITY ABOUT
FRYER HILL.

The organization of the Dold Mining Co., in Denver, and its subsequent lease of the Northern property, adjoining the Coronado in the Down Town section are recent events in the Leadville district that promise big things for the future. The Dold Mining Co. is an organization of prominent Denver business men headed by C. J. Dold, a pioneer mining man of Leadville, who in 1879 was actively interested in the Tuscon mine, on Iron hill. He is familiar with the entire territory, particularly the Down Town area, and predicts that it will develop into an important and heavy productive centre. The company is well financed and will make a thorough exploration of the Northern property, which comprises eight acres, adjoining the Coronado on the north and directly in the trend of the big Down Town ore-shoots that have been developed through the Penrose, Midas, Sixth Street, and Coronado shafts.

The Northern, and a large surrounding area, including the Capitol, Clipper, Congress, and Castle properties, have been in litigation for a number of years owing to the conflicting claims made by the Carleton brothers, and former Governor

Jesse F. McDonald, owner of a big tract in the Down Town district and manager of the Down Town Mines Co. which is now operating through the Penrose. Recently a decision was reached whereby the territory involved becomes the property of the Leadville Basin Mines Co., a Colorado corporation, in which both of the claimants become stockholders, with the Carleton interests in control.

The officers of the Leadville Basin Mines Co. are: J. K. Carleton, president; S. W. Eckman, treasurer; and S. M. Carleton, secretary. These three, with I. B. Humphreys, form the board of directors.

From the Leadville Basin Mines Co., the Dold Mining Co. has secured a ten-year lease on the Northern; and is placing the property in shape for operation. The shaft is 638 ft. deep and will be re-timbered. A large building has been moved onto the property, to be used as a hoist-room. The Colorado Power Co. is erecting lines to the property and installing transformers. A 52-hp. hoist is to be installed as soon as the buildings are ready.

The Northern and the surrounding territory, which the Dold Mining Co. is preparing to develop, is reported to contain three ore-horizons at as many contacts. The first contact was partly explored by past development, in the Northern and Coronado shafts lying between the white-porphyry and the Leadville blue lime. This contact underlies the greater part of the Leadville district. A second contact, of vastly more extensive mineralization, was found below a thin sheet of gray-porphyry in the blue lime. This contact was the source of an immense tonnage of ore extracted from the Coronado and Northern. The third contact, so-called, is the 'second contact' that is usually found in other parts of the district under the parting-quartzite in the white lime. This contact was reached and developed through the Coronado, but the Northern workings were never deep enough to reach it.

The possibility of the extensions of the third-contact ore-shoots of the Coronado continuing north into the Northern ground is the cause of the re-opening of the latter property at this time. It is stated that the Down Town Mines Co., developing the Coronado through the Penrose, has extracted ore from large deposits found right up to the Northern line.

The Coronado is 870 ft. deep, indicating that the Northern will have to be sunk 232 ft. to reach the contact. It is also stated that the presence of the Cloud City fault, traversing this territory between the Coronado and Northern, will make it necessary to sink the shaft of the latter still deeper to reach the ore.

That the developments at the Northern will meet with success is generally conceded. The property is in the centre of a rich area that has been productive of high-grade lead and zinc carbonate and silver chloride. Former operations at the Northern resulted in the extraction of ore worth hundreds of thousands of dollars, and it is believed that the third-contact orebodies will prove richer than those found above.

The Leadville Basin Mines Co. is also planning to undertake extensive development in its other holdings running north from the Northern into Poverty Flat. This territory is now one of the most promising sections in the district, and it will be thoroughly developed during the next year or two. The usual Leadville formations are all in place under the Flats, as is evidenced by the presence of the white-porphyry and blue lime in all of the shafts that have ever been put down in that area. The formations are much deeper here, however,

than in other parts of the district, owing to the succession of faults that have gradually raised them from the Down Town and Poverty Flat territories, east through Fryer, Carbonate, and Yankee hills. Deep mining will be necessary to uncover the orebodies in the Flats, and it is this development that the Leadville Basin Mines Co. will undertake.

Lead carbonate carrying hundreds of ounces of silver to the ton has been extracted from the old Seeley shaft by former operators, and similar ore is reported to have been found in the Delante property. The ore deposits, however, were not large nor continuous, but it is hoped that with greater depth they would be found to develop into extensive shoots.

It is stated by the owners of the Flat properties that an Eastern syndicate is being organized for the purpose of advancing operations throughout that section during the coming summer. Other enterprises are expected to follow, and it appears that considerable development will be undertaken in the territory. At present there are four properties active in the Poverty Flat area. The Jason, Alright, and Murcray, located near the slope of Fryer hill, are producing a steady tonnage of iron and manganese ores. The Davis shaft is being sunk to greater depth following small streaks of lead carbonate that were encountered on the 100-ft. level.

The Leadville Unit, on Fryer hill, continues the sinking of the Jamie Lee shaft which is now nearing a depth of 700 ft. The parting-quartzite was cut just above the 600-ft. mark, and since then the shaft has been in white-porphry and lime. Sinking will continue to the contact between the white lime and the gray-porphry where large orebodies are believed to exist. Several new discoveries have been made in the upper workings of the Jamie Lee, Tip Top, and Harvard, where development is being carried into new territory. A steady tonnage of ore is being extracted.

Lessees on the Hayden property, on Fryer hill, have just completed sinking the shaft an additional 100 ft. The shaft is now through the parting-quartzite and into the white lime. Driving in this latter formation is underway. This property is producing a steady tonnage of zinc carbonate.

Development in the lower formations underlying the parting-quartzite, in the Fryer hill section, is being followed with great interest by local mining men. This area is one of the most important sections of the district and the discovery of rich orebodies in the second contact will be followed by the sinking of many now idle shafts into the new ore-zone.

The Fortune mine, in south Evans gulch, is being prepared for the largest development campaign that has ever been undertaken in that famous old property. Under the direction of Manager John McNeece, the shaft is being re-timbered and a second compartment is being opened for hoisting. Driving into new territory on several of the old levels will follow. Travison & Co., leasing the lower workings of the Fortune below the level of the Yak tunnel, are rapidly removing the cave that recently blocked their winze. The old Fortune vein was being opened through workings from the winze and a large and rich ore-shoot had been uncovered at the time of the cave. Pumps have been installed in the Resurrection winze, which is 50 ft. deeper than the Travison workings, and the entire vein is being drained. It is stated that developments in ore will be resumed during the month and that steady shipments will be commenced early in May.

TERLINGUA, TEXAS

LARGE PRODUCTION AND EXTENSION OF OPERATION IN TERLINGUA DISTRICT.—MINES AND WORKS GUARDED BY TROOPS.

There has been a steady increase in the quicksilver output of the Terlingua district during the last several months. Besides the existing cinnabar mines that are being successfully operated, several claims are to be developed by new companies that have been organized for the purpose. At present the different furnaces in the district are treating about

80 tons of cinnabar ore daily. The output of quicksilver for the past 12 months is close to 10,000 flasks. The Mariposa Mining Co. has two 10-ton furnaces in operation, and other furnaces, owned by the Chicos Mining Co. and the Big Bend Mining Co., are producing large quantities of the metal. These three companies are the principal ones now operating in the district. James Normand of Marfa, Texas, is president of the Mariposa Mining Co.; Howard E. Perry, of Chicago, is president of the Chicos Mining Co.; and W. D. Burcham is general manager for the Big Bend Mining Co. The proved cinnabar district has a width east and west of about 16 miles. It is not known how long it is for the reason that well-defined veins have been traced across the Rio Grande into Mexico and for some distance south from the border.

The great advance that has been made in the price of quicksilver since the War began has made it a very profitable industry. But for the fact that Terlingua is situated 90 miles from the nearest railroad point, it is believed that the development of large deposits of cinnabar ore here would be much more extensive than they are now. In order to protect the different properties from possible damage or destruction by raiding bands from Mexico, military guards are maintained at all of the mines and furnaces. The Rio Grande also is patrolled constantly by United States troops.

HOUGHTON, MICHIGAN

A LONG LIFE STILL IN SIGHT FOR CALUMET & HECLA.—POTATO FARMS NOW POPULAR WITH THE MINERS.—THE CONTACT PROPERTY AS A POTATO RANCH.

Fifteen years ago, the late Horace J. Stevens, one of the best informed publicists on copper mining in the United States, went on record as limiting the life of the Calumet & Hecla to ten years as an active producer, and allowed five years more 'to clean up.' At the present time the Calumet & Hecla mine has openings which practically insure good ground at a reasonable rate of production for ten years ahead, and the company has more money per share in its treasury than ever before in its history; has just completed the most profitable year in its 52 years of existence; has financial interests well placed in subsidiaries that are certain to be profitable producers for 20 years, in three or four prominent cases, and generally has an outlook for the future that is better than at any time in its career.

There is a great deal of Calumet & Hecla stock held here in the copper country of Michigan, as there has been from the very first. Every copper-country boy, and native-son, remembers from his earliest childhood that his father's one ambition has always been to accumulate enough Calumet & Hecla stock to be comfortable in his old age. As a security native-sons consider it in the same class with government bonds. As for the end in sight, so certainly predicted by men like the late Mr. Stevens, the Calumet & Hecla management may well be depended upon to maintain the organization, produce the copper, and provide employment for its thousands of high-class expert workmen for many years to come, just as that same management decided 15 years ago, that while the end of the Calumet conglomerate-lode might be foreseen at some time in the future, that offered no excuse for the disintegration of this, the largest and most important copper mining corporation in northern Michigan.

And the end of the Calumet-conglomerate, as an important producer of copper, is by no means in sight. In the recent purchase of the Tamarack property by the Calumet & Hecla, the latter company comes into possession of a great deal of conglomerate-territory that could not be mined by the Tamarack as its own, and yet, that assures a profit to the Calumet & Hecla when handled through that corporation. While the outlay for this property was \$3,600,000, and to that must be added a considerable sum for the rehabilitation of No. 5 shaft, the

life of the Calumet-conglomerate is extended over a period of at least ten years at the northerly end.

In addition to the acquisition of this important section of Tamarack ground there is another important feature that ought to be considered in connection with the purchase of Tamarack. For instance, practically all of the Calumet & Hecla conglomerate shafts that have run to the boundary-line were in a grade of ore that could be operated at a profit, even at such great depth. It was not, of course, rich, like the conglomerate nearer the surface, but it was by no means too lean to work. Many of these shafts stopped because they had reached the Tamarack boundary-line. In the Hecla mine, No. 6 shaft is down 7874 ft., and 133 ft. under the 79th level. No. 7 is down 7977 ft., which is 140 ft. under the 80th level. At the South Hecla No. 8 is down 6102 ft. and sinking has been permanently discontinued at the 63rd level. The rich South Hecla shafts, No. 9 and 10, are down 8132 ft., 142 ft. under the 82nd level. At the Calumet, No. 2 shaft is 6186 ft. and sinking presumably will cease at the 63rd level, but this shaft, like some others, ceases because the Tamarack boundary-line is reached. Now that the Calumet & Hecla owns Tamarack, there is no boundary-line and while these depths once were considered formidable nothing but the poor quality of the rock will prevent a continuance.

Calumet shaft, No. 4, is down 7995 ft. and has to go to the boundary-line at the 81st level. The big double-shafts, No. 5 and 6, which connect with the Red Jacket perpendicular shaft, has attained a depth of 6155 ft., with the boundary at the 60th level, according to the last annual report, prepared before the Calumet & Hecla took over the Tamarack.

After many years of struggle, it may definitely be announced that the Contact, formerly Elm River, now is an assured commercial success. The old Elm River company operated as long as it was possible to collect assessments and pay its way. Then it retired, in 1910, and the Contact took its place—simply a change in name and the shareholders permitted to make an exchange, share for share, and continue to assume assessment responsibilities. No copper has been mined profitably since the first exploration work started. But now, the solution seems sure. There are 2300 acres of the best potato-soil in the Cloverland district on the Elm river. The agricultural experts agree on this. And the corporation as such has two chances, either to lease the potato-land, or raise potatoes instead of attempting to raise copper. This acreage, properly handled, ought to supply 500,000 bushels of potatoes at a net profit to the corporation of \$1,000,000 this year. Potatoes are selling here, in the greatest potato-growing section of the United States, at \$2.40 per bushel, delivered by farmers to the cars, wholesale.

Seriously speaking, on the potato question, it is interesting to note that the Calumet & Hecla company has offered to lease lands for potatoes, or other small farming-work, to its employees at practically no cost. As a matter of fact, every company-house, Calumet & Hecla, or otherwise, has a good-sized tract of land about it. And practically all of the miners have their little gardens. In order to assist in the garden-work, on a more elaborate scale, the Calumet & Hecla makes the flat offer to any of its workingmen to give them the use of fenced land for an insignificant rental, and is encouraging the organization of small potato-clubs among the working men. The average miner, with his eight hours on the job, has plenty of spare time for digging potatoes as well as copper, and the campaign to date has progressed to a point where the crop for 1917 is going to break all records unless climatic conditions are radically unusual.

The leaching-process, for a further saving of copper, is an assured success. Instead of handling 2000 tons daily, an additional plant will be built to handle 2000 more. The original plant handled only the sand from No. 2 re-grinding plant, but the new one will operate on sand from the mill. While there is a comparatively limited amount of copper extracted the

cost has been but six cents per pound. The oil-flotation experiments indicate assured success in treating slime.

In reply to numerous inquiries it might be stated that there has been no material betterment in the underground conditions at the Superior since the first of the year. The company has paid one dividend, and another was recently announced. Contrary to the general impression, however, the Superior has not gone out of business, nor is the end in sight. At present there is at least 280,000 tons of profitable rock to be mined. Sinking to the 33rd level is the present plan. From that depth a lateral will be run to the ore-shoot which showed from the 18th to the 21st levels, 1200 ft. from the shaft. If values continue to this greater depth there will be at least double the present ore-reserve in sight.

SUTTER CREEK, CALIFORNIA

CENTRAL EUREKA TO ENLARGE OPERATIONS.—THE NORTH STAR DEVELOPMENT WELL UNDER WAY.—MINERS' WAGES INCREASED.

The Central Eureka Mining Co. will soon be running its 40-stamp mill to full capacity, as sufficient rock has accumulated and reserves of ore have been blocked out so that it will not be necessary to keep from two to four of the batteries hung up, as has been done of late. Station-cutting is in progress both at the 3350 and 3425-ft. levels and in the meantime considerable rock is being obtained from the short drifts on these levels. A donkey-engine and small skip is still used for handling this rock, but as soon as the stations are enlarged and adequate chutes provided, the large skips will begin hoisting ore from this new portion of the shaft. Repair work is in progress on the tailing-dam, where a portion of the restraining-wall gave way during the winter floods. Fred Jost is the superintendent, and W. J. Bryant, foreman of the Central Eureka.

Good progress is being made in running the various cross-cuts from the North Star shaft of the South Keystone Consolidated Mines to prove the several claims of this group. Most of the work is being done on the 600-ft. level, where it has been found, after catching up slight caves, that a great deal more development work was done under former management than the present company anticipated, thereby shortening the time that will be required to reach the orebodies believed to exist in this promising ground. John A. McIntire of Sacramento, a director in this company, is at Sutter Creek this week.

The Plymouth Consolidated Mines Co. has addressed a circular letter to the mine-owners of the county, announcing an advance in the wages of employees, 25 cents per day, which it is understood will raise the average there to a level with what was paid at the Keystone, Original Amador, and Old Eureka prior to the strike. The mines last named were not seriously affected by the strike and the employees of the Plymouth Consolidated Mines returned to work upon the promise of this raise, after being out only a few days. A similar increase has been promised the Kennedy mine employees to take effect this month.

Charles Peters, a pioneer of Jackson, is endeavoring to interest capital in the Good Hope quartz mine at Jackson. The property consists of three full-sized claims on which very little development work has been done with the exception of one 125-ft. shaft. The Good Hope claim lies several hundred feet west of the Zeila mine and only 200 yards from the main part of the town of Jackson.

Prof. Geo. D. Lauderback, of the Geological Department of the University of California, with a party of 21 students from the University, has been exploring the mineral resources of Amador county for more than a week past.

Chas. Hoerchner, of Mokelumne Hill, Calaveras county, has located an antimony deposit on Esperanza creek, five miles

from that town. The deposit is said to be extensive and valuable.

The May Pole quartz mine, half a mile from Mokelumne Hill, resumed operations last week, when H. Blackmore, of Stockton, put men to work on two shifts, driving the adit ahead to tap the lead under the old shaft, sunk in the early '60s. This mine has been idle for the past three months.

TORONTO, CANADA

THE GOVERNMENT FIXES AN ARBITRARY TAX ON THE NICKEL INDUSTRY.—INDICATIONS OF SERIOUS LABOR TROUBLES.—IMPORTANT DEVELOPMENTS AT PORCUPINE.

As a result of the long-continued agitation over the nickel question the Ontario legislature has passed an act for the taxation of mines which increased considerably the comparatively light tax formerly imposed on the nickel-mining industry. The Provincial tax, supposed to be levied on all mining companies, was 3% on the profits, but some years since the International Nickel Co., by a special arrangement with the Government, obtained a flat-rate of \$40,000 per annum. Since then their output has been enormously increased. Another cause of dissatisfaction was that the company operating the Sudbury nickel mines, the Canadian Copper Co., a subsidiary of the International, consigned its output to the parent company at a nominal price, which did not represent anything like its real value, thereby lowering the basis for taxation. The new tax-bill, as finally adopted, discriminates between nickel and nickel-copper companies, and other mining companies, leaving the position of the latter practically as it was before. The tax on the nickel and nickel-copper concerns is fixed as follows: On profits in excess of \$10,000 and up to \$5,000,000, 5%; over \$5,000,000 and up to \$10,000,000, 6%; and so on, the rate increasing by 1% for every additional \$5,000,000 of profits. Other mining companies must pay, as at present, 3% on profits over \$10,000 and up to \$1,000,000, and on profits above that amount an additional rate of 1% for every \$5,000,000 additional profit. Important features of the bill are the provisions for estimating profits, which will no longer be figured upon the nominal values placed on the matte exported for treatment in the United States. It is enacted that the value of the refined metal, less the costs of treatment, marketing, and 15% allowance for depreciation, are to be taken as the profit, and that sales of nickel ore, or matte, by a subsidiary company to a principal that controls the value, are not to be considered *bona fide*. The tax, furthermore, is made retro-active as of January 1, 1915. It is officially estimated that the tax will compel the International company to contribute \$1,000,000 per year to the Provincial treasury, instead of \$40,000. Even this drastic measure does not satisfy the extremists, who opposed its enactment in a series of bitter debates, on the ground that it was not sufficiently far-reaching. The Liberal members, who have taken up the Government ownership of nickel mines as a popular election-cry, assailed the International as a pro-German monopoly, clamored for absolute Government control of the nickel industry, and wanted the bill made retro-active, back to the year 1912. They introduced a resolution calling for Government control of the refining of nickel, which though defeated by a straight party vote of 22 yeas to 47 nays, doubtless served its purpose of making a record for the next election campaign.

The Porcupine mine-owners are likely to have to contend with serious labor troubles before long, as a strong agitation among the miners of all the northern Ontario camps for an increase of 50c. per day all round is making headway. This was resolved upon at a recent convention of miners held at Cobalt, but the demand has not yet been formally presented. To head off the movement several of the Cobalt mine-owners have offered to give bonuses based on the selling price of silver—25c. per day when silver is over 60c. per oz., 50c. when over

70c., and 75c. when over 80c. But the men do not take kindly to the proposition as they regard the bonus as unstable and they want a permanent increase.

The mining companies of Porcupine are in a different position, for, as they say, the value of gold is stationary, and consequently they are not disposed to meet the demands for an increase. In case of a strike several of the mine-owners say they will close down. The output is already considerably curtailed by labor shortage. The Dome has pushed its workings on the 700-ft. level into the territory of the Dome Extension, on which it holds an option, and is developing deposits of high-grade ore. It is anticipated that the 1000-ton unit of the Hollinger Consolidated mill, now under construction, will be completed about the end of June. This will increase the milling capacity to about 2800 tons per day. The shareholders of the Dome Lake have authorized an increase in the capital from \$2,000,000 to \$3,000,000. Plans are under consideration for milling West Dome ore at the Dome Lake mill. The shaft on the North Thompson side of the Vipond-North Thompson has been timbered and a station cut at the 600-ft. level, where a drift is being run to connect with the old Vipond workings. At the Newray, a cross-cut on the 400-ft. level passed through a vein 5 ft. wide. The Slade-Forbes Asbestos Co. is shipping crude asbestos from its property to Cincinnati.

The McKinley-Darragh has ordered a second flotation-plant with a capacity of 200 tons, raising the total capacity to 400 tons daily. The Buffalo flotation-plant is now running at the rate of 400 tons daily. The Adanac has discovered ruby silver in a second vein in cross-cutting on the 400-ft. level. The Sukverado, of Gowganda, is installing a 100-hp. boiler and other equipment.

JOPLIN, MISSOURI

SPELTER FOR GOVERNMENT NEEDS AT COST.—PLANS FOR THE OCTOBER MEETING OF THE A. I. M. E.

The outstanding feature of the week's developments in the Joplin district was the discussion of the plan for supplying spelter for the needs of the Government on the basis of actual cost. The plan, so far as disclosed, contemplates the ore producers turning over 10% of their output at cost; the smelters then taking the ore and smelting it at cost, and turning the product over to the Government. On a basis of the present production in the Joplin district, this would result in a supply for the Government of from 1000 to 1200 tons of ore per week which should yield from 500 to 600 tons of metal. This would provide the Government with about 30,000 tons of spelter per year from the Joplin district alone, and if the remainder of the zinc-producing country make the same offer, it would give the Government all of the spelter needed for munition manufacturing at the actual cost of production. On the basis of present mining and smelting costs, spelter should be turned at from 5c. to 7c. per lb. f.o.b. smelters. This figure would compare very well with the ratio of prices already said to have been obtained by the Government for lead and copper which it will need in munition manufacture.

The Missouri section of the American Institute of Mining Engineers is now holding committee meetings and organizing for the entertainment and program to be given at the meeting of the Institute to be held in October of this year. The Missouri section, which will act in the capacity of host to the Institute, will hold a meeting at the Connor hotel, Tuesday evening, April 17, for the preliminary working out of the plans. Dr. H. A. Buehler, chairman of the executive committee, has called a meeting of the section, and it is expected that in addition to the executive committee, there will be a large number of the Institute members at the meeting in Joplin, April 17.

In addition to the Joplin-district membership, engineers from the oil-region, at Tulsa, Oklahoma, are greatly interested and are expected to join in the entertainment plans.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ARIZONA

MOHAVE COUNTY

(Special Correspondence.)—Oatman officials of the United Eastern Mining Co. announce that in March the mill treated 6585 tons of ore which averaged \$23.84 per ton, making an extraction of 96.15% of the assay value. The bullion output was \$156,962.59. The Big Jim Gold Mining Co. has called a meeting of the stockholders at Phoenix, Arizona, for April 24, for the purpose of ratifying the sale of the Big Jim mine to the United Eastern Mining Co. and for the exchange of Big Jim stock for stock of the Big Jim Consolidated, share for share. The Big Jim Consolidated, May 1, will commence the development of the Bluebird property which end-lines the United Eastern on the west. Big Jim stockholders will receive one share of United Eastern for six shares of Big Jim, which they may hold or sell as they will. President N. P. Moerdyke, of the Tom Reed Gold Mines Co., who spent the past week inspecting the company's mines, states that the Ben Harrison (old) workings of the mine contain 40,000 tons of ore of which 10,000 tons is broken in the stopes and 30,000 tons developed. This will supply the new 300-ton mill now nearing completion and no ore will be drawn from the Aztec workings until an aerial-tramway is constructed, excepting that taken out in development. Material for a 4000-ft. tramway will be ordered as soon as a representative of the manufacturing company arrives. It is expected that the mill will be completed in five weeks. The old mill produced in 1916 \$528,946 from 39,182 tons of ore averaging \$13.50. Production from the new mill will be at the rate of \$4500 per day from 300 tons of \$15 ore, according to calculations.—The cross-cut on the 500-ft. level of the Nellie is near the foot-wall of the vein, according to measurements. The shaft went through the vein at 390 ft. and cut 26 ft. of \$9 ore.

Oatman, April 16.

On April 10 the sheriff received information that men were about to remove the mill from the Holy Moses claim in Gold Flat, near Hancock station, and upon going to that place found three men dismantling one of the engines. He placed all three under arrest and lodged them in jail.

Harvey Klotach, manager for the Yucca Tungsten Mines Co., has contracted with J. W. Fettes to haul 200 tons of machinery from Yucca to the site of the mill close to the property. When the new mill is ready to run there will be a large tonnage of ore available. During the past year \$100,000 worth of tungsten has been shipped to Pittsburg, the ore being dressed in a small mill with hand-jigs. A big compressor and machine-drills have been installed at the lower tunnel and the mine is now being opened several hundred feet below the old workings.

PIMA COUNTY

The first ore of the New Cornelia Copper Co. was crushed and delivered to the first of the 12 tanks of the 5000-ton leaching-plant last week. This is the first large copper carbonate leaching-plant in this country and the second largest in the world.

It is expected that it will require from 15 to 20 days to bring the 25,000 tons of acid solution up to a strength in copper contents that is necessary for the electrolytic precipitation. It will then require another 12 or 14 days before the first cathodes will be ready for shipment.

The construction of this plant was begun a little over a

year ago and was expected to be in operation not later than June 1 of this year. Systematic drilling has shown the existence of 40,000,000 tons of ore of which about one-third is carbonate and two-thirds sulphide, averaging in all, 1.51% copper. There is practically no overburden therefore no stripping. The running will be by steam-shovel. The copper is dissolved with sulphuric acid produced at the Calumet & Arizona smelter at Douglas. The plant will cost \$4,000,000. The Calumet & Arizona Mining Co. owns approximately 76% of the stock of this company.

CALIFORNIA

The report for the week ended April 14 shows 20 new oil wells, making a total of 323 since the first of the year, 34 tests of water shut-off, 19 deepening or re-drilling jobs, and 12 abandonments.

ALPINE COUNTY

(Special Correspondence.)—The old Leviathan mine, 8 miles east of Markleeville, is again in operation after a long idleness. The mine was successfully worked between 1863 and 1872, when high-grade ore was shipped to works at Dayton, where bluestone was manufactured for use in the silver mills at Virginia City. Large bodies of ore, some of which is high-grade, have been discovered and a company, known as the Leviathan Copper System, now proposes to develop the mine. The work will be done under the direction of John L. Henry. The office of the company is in Los Angeles.

Markleeville, April 19.

BUTTE COUNTY

Ten men are employed at the chrome deposits on the Curtis property, that was recently taken under option by F. Alexander.

CALAVERAS COUNTY

(Special Correspondence.)—A converter has just been installed at the smelter of the Penn Chemical Co. at Campo Seco, and the matte from the reverberatory furnace will henceforth be shipped as blister copper. The manager, A. P. Busey, Jr., has contracted with the Pacific Gas & Electric Co. for current, and electric power will be substituted for steam throughout the plant. A new electric hoist is being installed, and an underground electric hoisting station is being put in at the 1400-ft. level, capable of serving the operations of the mine to a depth of 2500 ft. below that point.

Campo Seco, April 18.

NEVADA COUNTY

(Special Correspondence.)—A compressor and motor have been installed at the California mine, at Deadman Flat, four miles below town, and construction of a 10-stamp mill has been decided on. Sinking is proceeding in the shaft and good ore is said to be showing at several points. The property was lately acquired by King C. Gillette, of Los Angeles.

It is reported that a flotation-unit will be included in the new equipment to be added to the Central mill of the North Star Co., that has been making tests on its ores with flotation, and recently placed a small plant in commission at its Champion mine, near Nevada City, for the treatment of tailing. The old North Star mill will be dismantled. Splendid ore is being developed below the 6300-ft. level, and a large tonnage continues to be drawn from the North Star vein.

The 10-stamp addition to the mill of the Golden Center Co. is in operation and construction of the cyanide-plant is pro-

gressing. The main orebody has been opened to a depth of 1000 ft., and superintendent Charles K. Brockington is preparing to explore large areas of virgin ground. Frank Vestal, formerly with the Empire Mines Co., is in charge of the mill.

The new owners of the Union Hill mine, San Francisco men, have made the final payment on the property and have arranged for more vigorous work. The shaft has been deepened and lateral work started to intersect the Union Hill and other veins. Besides yielding much rich gold ore this property is noted for its production of high-grade scheelite.

Five hundred acres near Cherokee, that are covered with tailing from old hydraulic properties, have been taken under option by the Guggenheims, according to the owners. The ground also contains much virgin gravel. Testing of the ground is proceeding and it is said an attempt will be made to recover the gold by means of dredges.

Specimen ore is again coming from the upper workings of the Red Ledge mine, near Washington. A good tonnage of milling ore is blocked out and it is planned to run the mill steadily. Clyde Cole and the Williamson brothers, of Washington, are the owners.

Grass Valley, April 15.

At the Allison Ranch mine, the water is being pumped from the shaft at the rate of 800 to 1000 gal. per minute, says the Grass Valley Union, with but one of the two electrically-driven pumps in operation. The shaft, an incline, is 1675 ft. deep, and there are stated to be 9000 ft. of drifts besides other workings. It is estimated by C. W. Brockington, the manager, that in two months the workings will have been unwatered to the bottom of the mine. The Allison Ranch mine was discovered in 1855, and was worked for over 11 years, during which time it is said to have produced \$2,300,000 in gold. Small rich shoots occurred in the vein with low-grade ore between. The rich ore ran from \$100 to \$200 per ton, the average, including the low-grade ore, being about \$50 per ton. It is stated that 46,000 tons was milled. In its early history the vein was stoped for 1000 ft. along its strike. It was always an expensive mine to operate, owing to the great influx of water, and the extreme hardness of the ore and the rock inclosing the vein—a hard tough greenstone. The mine was closed-down the latter part of 1866, but was re-opened early in 1869. After that it was frequently idle and again opened, until, after a long idleness, it was bought by John W. Mackay and considerable work was done on it, but it was again closed and remained idle for a long time. It was in operation, however, in 1900 for a short while, but the water could not be controlled, and the mine was once more shut-down and had remained idle ever since until recently. With the new electrically-driven pumps little trouble is anticipated by the present management. The new owners, the Grass Valley Consolidated Mines Co., certainly show abundant faith in the outcome of its attempt to operate this noted old mine, for, while the water has scarcely begun to be lowered in the deep shaft, it has already built a 20-stamp mill and provided every modern device necessary for the treatment of ore such as commonly occurs in the Grass Valley region.

SAN BERNARDINO COUNTY

(Special Correspondence.)—Samuel S. Arentz and W. A. Perkins, of Ogden, have made the final payment on the Ingomar mine near Calada, and recently purchased for cash, from C. L. Hyde and associates of San Diego, the Milford No. 2 claim, which adjoins the Ingomar on the west. Three claims now comprise the group. S. S. Arentz is operating the property and has 20 men employed. During March four cars of zinc carbonate and one car of galena (crude ore) were shipped, netting on board cars at Roach, Nevada, \$8000, exclusive of mining costs. Ore is lowered from cliffs on a 1400-ft. two-bucket tram and hauled 16 miles to the railroad by a six-ton Knox tractor. The property is 20 miles south of Goodsprings, Nevada.

Roach, April 16.

At the Belmont mine, at Goldstone, Drum & Clancey are developing the vein.—James Gatkins is reported to have sold a part of his property adjoining the Goldstone Mining Co.'s mines for \$6000, according to the *Barstow Printer*.—A property close to the Red-Bridg mine has shipped recently 300 lb. of ore said to be valued at \$1500.—A telephone line connecting Barstow and Goldstone is to be built. The cost will be raised by popular subscription, enough having been already secured to purchase the poles and wire.—At the property of the Goldstone Mining Co. the mill is about ready and production soon will commence. Nels Anderson has succeeded Mr. Greenwalt as superintendent, the latter having gone to Nevada.

SISKIYOU COUNTY

(Special Correspondence.)—The Hunter's Paradise copper mine, 10 miles below Happy Camp, on the Klamath river, is held under option by the Gray Eagle Mines Co. of Maine, and identified with interests of W. B. Thompson, of New York.

Fifteen men have been steadily employed in exploration and development since last September. Buildings, trails, and telephone-lines have been put into working-order. The group comprises several claims, three of which recently were patented. Old work amounting to 1100 ft. underground, done by the General Development Co., was dropped at the inception of the War.

The present prospective buyers have sunk a 6 by 8-ft. shaft 100 ft. in the vein, and at the bottom a 79-ft. cross-cut through 46 ft. of vein proves the width at this point to be 38 ft. This was about the width at the surface where the croppings assayed from wall to wall, 0.1% copper; 0.01 oz. gold; silver, a trace. The 46 ft. from wall to wall at the bottom of this shaft, 70 ft. vertically from the collar, assays 0.8% copper; 0.03 oz. gold; silver, 0.25 oz. From the east a cross-cut adit is being driven through the hanging wall to the vein at a depth of 205 ft. (vertical) under the bottom of the shaft; being 275 ft. (vertical) beneath the collar. This adit was in 458 ft. on April 1, and had entered the hanging-wall porphyry, thought to be 120 ft. thick. It is expected that copper ore of commercial grade will be cut on this level, if not where cut by the adit, then, by driving south along the vein.

A second hanging-wall cross-cut adit is being driven to the vein 1500 ft. southerly from the shaft. This is now in 510 ft., having entered the porphyry that everywhere overlies the vein, at a distance of 307 ft. from the portal.

Considerable time and money was dissipated in an adit 528 ft. long in the foot-wall, by which it was believed the vein could have been tapped. Extremely heavy ground necessitated the abandonment of this costly adit.

A segment of the upper part of this vein, approximately 900 ft. long and 500 ft. deep at the north end has apparently been faulted and thrust westerly 1000 ft. into Lane's gulch. The hanging wall of this part of the vein lying in Lane's gulch has disappeared, giving the impression, at first, that this 40-ft. vein is here more than 400 ft. wide. This dislocation of the upper segment of the vein is attributable to the twisting effects of a surface serpentine 'flow,' so common in the western Klamath mountains, as well as throughout the Coast Range. This serpentine approaches within 300 ft. of the vein at most points, except where it shoved off the upper segment of the vein and there of course it entirely over-thrust the vein. Subsequent faulting, and finally, the erosion of that part of this serpentine that caps the lower part of the vein, has exposed the vein in place with a gossan outcrop that is insignificant in comparison with the immense overturned segment in Lane's gulch.

It is clear that except for surface jointing-seams no disturbance or dislocation by the serpentine will be encountered beneath the land surface over which it originally spread. This is also true at the Gray Eagle property 16 miles distant.

Until the deeper adits, now being driven, reach the vein, no new appraisal of this important prospect can be made.

All work is being done by hand. The option has two years yet to run.

Happy Camp, April 18.

TRINITY COUNTY

The Trinity Gold Dredging Co. has let the contract for building a second dredge, the cost of which will be close to \$350,000. The company already has one dredge in operation, the old Alta Bert. The new boat will have three times the capacity of the old one. It will have 82 buckets of 18 cu. ft. capacity. The present boat's buckets have a capacity of 9 cu. ft. The new boat will be capable of dredging 420,000 cu. yd. per month.

The hull, which will be of wood, will be 140 ft. long and 65 ft. beam. The timber for the hull will be sawed in the company's mill. The machinery will be made in Ohio. It has not been determined whether the heavy hauling of machinery will be made from Delta or from Redding. The company owns 3600 acres of ground and enough of it is gold-bearing to keep two dredges busy for 15 years or more.

COLORADO

BOULDER COUNTY

(Special Correspondence.)—The Boulder Tungsten Production Co. is grading for a new reduction-plant that will be situated in West Boulder. The company either owns or controls a number of important tungsten-producing mines and proposes not only to concentrate the ore but to make ferro-tungsten. The object of the company is to make a product that can be sold direct to the consumers, thus eliminating the middlemen and brokers, and it is hoped thereby to give the industry in Colorado much greater stability.

At the Horsfall mine, at Gold Hill, which years ago was one of the largest and richest producers of high-grade gold ore, new buildings for a plant of modern machinery are being built. The shaft is being re-timbered and the entire property put in first-class condition.

C. E. Bradenburg, of Camp Brainard, has made a rich strike of gold ore that is creating a boom in that district.—Denver mining men have taken over the Snowbound mine and will supply capital for the development.—The big mill at Cardinal is to be remodeled and will include flotation. It will handle custom work, which is what is needed here.—The Huron mine, at Eldora, has been sold to Denver parties and work will immediately be started.—W. F. Harper will start the Mogul mine in a few days, with a large force.—The Revenge mine, at Last Lake, four miles west of Eldora, has produced the richest gold ore ever found in Boulder county. It is sufficiently developed to warrant the erection of a modern mill, which the owners say they will do this year.—Harry Barbee, who has an extension of the Revenge, is pushing development work as fast as it can be done.—The Kohlman cross-cut adit is progressing rapidly and the objective point will soon be reached. A mill is contemplated on the Mairs wagon-road, on Middle Boulder creek, which is near the portal of the tunnel.—Postmaster W. C. Spratt has made a big strike on his property, the vein being over 8½ ft. wide, carrying high-grade gold ore.—John A. Wilson, of Woodlawn Heights, is doing extensive work on his properties.—Caribou, the oldest and richest silver camp in the early days of this State, is getting out its regular shipments from the Caribou mine. Extensive improvements are contemplated at the mill.

The oil craze has again hit this State and the people have gone wild over it. Wild-cat stock schemes are flooding the whole United States. Denver is the hot-bed of the schemers and stringent laws should be passed to protect the unwary. Such schemes do untold injury to the legitimate mining industry.

Eldora, April 20.

(Special Correspondence.)—Through a legislative investigating committee the State of Colorado is going to make a

searching and thorough investigation of the so-called smelter-trust. The ore-producers want to know why they deliver a certain consignment of ore and do not get anywhere near the value in that consignment when the smelter settles.

Three years ago the mining men of Colorado organized the Colorado Metal Mining Association, backed by the leading miners in the State, and then began to demand an investigation of the smelters. This organization proved strong enough to go before the legislature, just adjourned, and, notwithstanding a great deal of opposition, secured the passage of a law for such an investigation with an appropriation sufficiently large to carry out the purposes of the law. The matter has been held up for some time by the Attorney General, who has finally decided that the law is constitutional and the committee will get down to work at once. The members of the committee are Senators Fincher and Candlish, and Representatives Ardourel, McDonald, and Nagel—all from mining counties.

The Colorado Metal Mining Association, a semi-official organization with offices in the Capitol building, will join with the legislative committee in making the investigation complete and thorough.

Denver, April 18.

CLEAR CREEK COUNTY

The Colorado Central Co., according to the Georgetown *Courier*, has increased its working force, and will make further additions to it, as the ground is opened to make a place for them.

The test-mill at the mine is doing good work and a flotation concentrate of combined lead and zinc is being separated, giving clean separations of high-grade in each metal.

The Marshall adit, which has been cleaned out to its extreme west end, has disclosed large bodies of low-grade ore, and also a fine vein of ruby silver and gray copper.

In the Equator adit the zinc orebody is 6 ft. wide, including a solid vein of 16 in., the rest being small veins close together. Concentration of this orebody at the test-mill has resulted in a concentrate that returns 14 oz. of silver per ton, with 45% zinc. The lead concentrate carries 450 oz. silver per ton and 81% lead. The fillings of the old stope on this level are full of zinc ore which is as high-grade as that in the orebody.

The driving of the Ocean Wave adit is going steadily ahead, and it is the intention of the company to drive this adit to the western end-line of the property.

IDAHO

CUSTER COUNTY

Fred H. Vahrenkamp, president and general manager of the Copper Basin Mining Co., operating near Mackay, reports the mine in splendid condition.

The company has blocked out an orebody 600 ft. long, 208 ft. wide, and 135 ft. deep. It measures 700,000 tons and carries 3½% copper, 2 oz. silver, and 80c. in gold, a total value of approximately \$24 per ton.

The snow is too soft to permit hauling, but spring is approaching, and within the next 30 days shipping will begin at the rate of 100 tons per day.

Mr. Vahrenkamp is making arrangements for motor trucks and trailers for the haul to Mackay, which is 23 miles distant.

In the development of this great orebody the hanging wall has not as yet been encountered, but in several places from 12 to 14 ft. of ore that carries from 12 to 20% copper has been developed. Plans are being made for a mill of 500 tons daily capacity.

MICHIGAN

Houghton County

(Special Correspondence.)—Production of rock from No. 7, Quincy shaft, is now 12,000 tons monthly. The production from No. 2 shaft, 18,000 tons. Laterals from the 44th to the 53rd levels, inclusive, at No. 2 are opening fine ground. In

No. 7, laterals from the 56th to the 71st are all in fine-looking ground. The copper output is sold up to August at good prices. There is no truth in report of a new mill, as the present arrangements for handling No. 7 rock at the Quincy mill are satisfactory and the Hancock Con. owns an interest with the Calumet & Hecla subsidiaries in the Point Mills plant. The best-looking Hancock rock is coming from No. 4 lode, west, where a lot of heavy copper, mass and barrel, is coming out. A cross-cut is running from No. 7 to the west lode. The characteristics of the formation are similar to those of the Quincy—barren ground for a time and then a widening of the lode and rich bunches of mass and barrel copper.

The mill-run on Cherokee rock, taken out in exploration work and hauled from the mine to the Copper Range siding on sleighs during the winter, is showing sensational copper. The bulk of the rock is producing No. 1 copper in the mill. The mill-run likely will net the company a substantial sum at this time.

Hancock, April 18.

NEVADA

HUMBOLDT COUNTY

Seventeen bars of bullion was the sum of a shipment from the Rochester mill which passed through Lovelock, during the past week, says the *Review-Miner*.

Some high-grade specimens have been taken from the slag-piles of the old Oreana smelter this week, which show the wastefulness of the former methods of treating ores there. One piece was a slab of almost pure metal consisting of silver, lead, and antimony, which had formed in the crevices of the dump. This slab would weigh about 20 lb. and is but one of many which are being taken out during the process of shipping this slag.

NYE COUNTY

(Special Correspondence.)—By the payment of \$54,000 on April 11 the Manhattan Consolidated Co. settled the litigation with the White Caps Co. that has been pending for five years. Some rich ore recently was encountered in the Consolidated, and, with all danger of litigation past, the management is preparing to increase the working force and begin making a substantial output.

The Wedge roaster for the plant of the White Caps Co. has arrived, being freighted from Tonopah by teams of from 16 to 24 animals. The crushing-equipment has been assembled and the management expects to have the mill in operation within a short time. It is officially stated that new development work on the 415-ft. level is proving satisfactory. Production of ore from the 315-ft. level will begin as soon as the mill is ready for service.

Vigorous work is proceeding at the Union Amalgamated, Morning Glory, Big Pine, Big Four, and several other properties. Preliminary steps have been taken for re-organization of the Original Manhattan Co. Under control of the Koontz interests, of Goldfield, the Mustang is to be energetically worked on company account. The important strikes in the White Caps and Consolidated mines have rejuvenated the district, but some mine-owners are showing a disposition to prefer the printing-press to the machine-drill as a means of securing publicity.

Manhattan, April 15.

(Special Correspondence.)—A shoot of shipping ore, 40 in. wide, has been opened in the raise from the 1050-ft. level of the North Star. It is apparently trending toward No. 1 raise and a cross-cut will be run from that point to find its extension. A shipment is ready for the West End mill. Ore of fair-grade is showing in the raise from the 1135-ft. level.

The Victor shaft of the Tonopah Extension has been practically freed of water after much trouble, and repairs are progressing. From the 1540-ft. level, east and west drifts and raises are advancing in low-grade quartz. Intermediate west drift, 539 ft. from the 1350-ft. level station, is advancing in

excellent ore, the vein having widened from 5 to 6 ft. On the 1260-ft. level of No. 2 shaft, stoping is proceeding on the Murray, Merger, and O. K. veins, the Murray and Merger showing widths of 8 ft. of good ore. The mill is treating 2380 tons weekly.

The Belmont Co. is pressing work from the 800-ft. level to block out the new 761 vein, that is said to average 20 ft. wide with most of the ore of good milling grade. Stoping has begun and indications point to a large tonnage of good ore below the 700-ft. level. The Rhyolite, Rescue, Shaft, and Mizpah-Fault veins are yielding good ore in the deeper levels.

The Proskey Regent group of 17 claims at Rawhide has been acquired by the Mogul Mining Co., composed of Eastern capitalists. Equipment includes two hoisting-plants, compressors, and power-drills. One shaft is down 150 ft. A. S. Proskey is superintendent. The Mogul company also operates a gold property near Charlotte, North Carolina.

Tonopah, April 16.

Ore production of Tonopah mines for the week ended April 13 was as follows, according to the *Tonopah Miner*:

The Tonopah Belmont sent to the mill 3024 tons, the Tonopah Mining 2100 tons, the Tonopah Extension 2380 tons, the Jim Butler 700 tons, the West End 780 tons, the Rescue 251 tons, the Halifax 160 tons, and the Montana 66 tons, making the total production for the week 9461 tons, the estimated value being \$175,028. This valuation is calculated on the gross milling value of the ore.

The Tonopah Mining Co. last week shipped 53 bars of mill-silver, valued at \$87,500. During the same period the Tonopah Belmont Development Co. shipped 47 bars of bullion and 42 tons of concentrate from the mill at Tonopah, and 23 bars of bullion from the plant at Miller. The bullion from the Tonopah mill weighed 58,778 oz. and that from Miller 44,099 oz. The total shipment, including the concentrate, was valued at \$133,689.30.

The West End Co. has discovered a new vein in the California mine, which was bought from the Ohio Tonopah several years ago. The recent discovery was made in a cross-cut far west of any of the old workings of the West End property. The vein occurs at the contact of the West End rhyolite on the foot-wall and trachyte on the hanging wall. As yet no information as to the value of the ore found in the newly discovered vein is given out by the West End management, but as the discovery is in undeveloped territory it has created much interest in that part of the district.

STOREY COUNTY

It is reported officially that some very good ore is being developed between the 2700 and 2900-ft. levels of the Mexican mine, on the Comstock Lode, where ore running \$60 per ton has been found in the Patton winze connecting the levels mentioned. The ore is directly beneath a bonanza orebody mined in the ground between the 2200 and 2500-ft. levels of the Mexican, and from which over \$1,000,000 was taken.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—At the Trilby mine the bottom level is being advanced to the east and results thus far are good. The property is owned by H. O. Bursum and the Kirkpatrick estate.—Owners of the Iron group, in south part of the district, have been developing continuously for several months, driving a cross-cut adit which will cut the vein at a depth of about 150 ft. It will take several weeks more to reach the point.—Development of 900-ft. level in the Last Chance mine is being pushed both east and west, with encouraging results. This property has been a continuous producer of gold and silver for over 13 years, during which time upward of \$5,000,000 gross has been mined. Its successful operation was initially due to the energies of Ernest Craig, who subsequently returned to England.

The Oaks Co. is shipping ore to a custom-mill from both the Clifton and Maud S. properties. The latter was only recently taken over under lease and the results of work in the brief interval are meeting the anticipations of the management. The company has also arranged with the owner of the Deep Down whereby this property is added to its central group, comprising the Clifton, Eberle, Maud S., and Deep Down, occupying a position in the district that will have a controlling influence on future operations. The Deep Down shaft, near the centre of this group, now down about 250 ft., is being re-timbered, the head-frame overhauled, and preparations made for installing a hoist, compressor, and pumps, when it will be continued to 500 ft. and drifts extended into adjacent territory. The group as a whole has produced around \$1,000,000 in the past from what are now considered little more than surface developments.

From operations covering last half of March the Socorro Mining & Milling Co. shipped 18 bars of gold-silver bullion, an increase of 4 bars over the production for the first half of the month.

The Mogollon Mines Co.'s output for the last half of March was 17 bars of gold-silver bullion, compared with 13 bars for the first 15 days of the month. The company recently paid a 5% dividend on outstanding stock.

At the Johnson mine, owned and operated by the Socorro Co., a compressor was recently installed and machine-drills are now employed in the development work, and in advancing the lower levels.

A new oil-burning furnace has superseded the old-time coal-forge in the blacksmith-shop at the Mogollon Mines Co.'s plant, effecting a marked reduction in steel-sharpening cost.

At a special meeting of the stockholders of The Oaks Co. in March its common stock was increased from \$500,000 to \$1,000,000 and its preferred stock changed from a 10% non-cumulative to a 7% cumulative stock and made preferred as to both dividends and assets. Including that of March 1, four consecutive monthly dividends of 1% each were paid on outstanding preferred, and on April 1 the disbursement was 1½%, to meet conditions of the new issue of stock. The next dividend of 1½% will be paid July 1 and quarterly thereafter.

Mogollon, April 18.

OREGON

JACKSON COUNTY

(Special Correspondence.)—The history of quicksilver in Gold Hill district dates back to 1878, when Wm. Mayfield, Sr., an early settler in Rogue River valley, discovered cinnabar on the property known as the Mercur claim, now owned by Dr. W. P. Chisholm, of Gold Hill. The mine is 12 miles north of Gold Hill, and comprises 20 acres. It is contiguous to the Little Jean, and the 36 claims held by the Utah Quicksilver Co., of Salt Lake City. From the time of discovery, and until he sold the property to Chisholm in 1900, Mayfield annually distilled mercury from the ore by roasting it in a crude manner. He disposed of it to the placer miners in this district, who used it in their sluices to catch the flour-gold. After Chisholm purchased the Mercur claim he located the Little Jean, an extension on the Mercur vein. These two claims were inactive until two years ago when Chisholm employed H. A. Ray and G. L. Haff, the discoverers of scheelite in this district, to develop his properties. They exposed the vein at intervals by adits for 2000 ft.; the greatest depth attained was 75 ft. Since that time the Utah people, and others, have located the main vein for several miles on the north and east. The strike of this vein is N. 53° W., and at an elevation of 2500 ft. It occurs along a granite-sandstone contact, where the granite is in part pegmatitic. The mineralized zone is from 100 to 200 ft. wide. It is not a well-defined vein, but is mineralized along an irregular contact. The ore, or mass, contains cinnabar, native mercury, pyrite, gold, zinc, silver, and a heavy black mineral resembling meta-cinnabarite. Samples taken from all

of the adits assayed from \$5 to \$6 per ton in gold, \$5 in silver, 2½% zinc, and 1% mercury. The cinnabar appears all through the rock and also in the hanging and foot-walls in the form of seams and kidneys. The seams are from 6 to 20 in. thick, and average 17% mercury. This last year Chisholm has employed two miners in developing his property, and during this time they have retorted and shipped 800 lb. of mercury, using a bench of three 6-in. retorts 4 ft. long. During this time Samuel Bertleson, of the Utah company, has retorted and marketed from 600 to 800 lb. of quicksilver from the Rainier claim. The Mountain King quicksilver mine situated two miles south of the Chisholm group seems to be on the same vein. The same formation is found at both properties. The vein on the Mountain King strikes nearly west. Except in the solid quartzite, much faulting is in evidence in all directions. The Mountain King is owned by J. R. Hayes, of Detroit, Michigan, who is represented here by Alfred Lewis, of Gold Hill. This property consists of 800 acres of patented land, and is covered with valuable fir timber. This property was worked the past season under a lease and option held by J. A. Robinson, of San Francisco, who did considerable development work on the property. This property and the Chisholm group are the only two mercury properties in this district which have been extensively developed.

Gold Hill, April 16.

TEXAS

TRAVIS COUNTY

(Special Correspondence.)—R. C. Walker of Austin is developing a large deposit of celestite, situated three miles north of here. He recently made a shipment of a carload to Philadelphia, and this is to be followed by others that will go to fill an initial order for several hundred tons. This ore will be used in the manufacture of fusees, and for other purposes, and is in large demand at this time. Mr. Walker will install additional equipment for enlarging the work upon his property. The ore deposit is shown to be large by the explorations so far made.

Austin, April 18.

CANADA

ONTARIO

(Special Correspondence.)—The shaft of the Porcupine V. N. T. has reached a depth of 620 ft. A station has been cut at the 600-ft. level sufficiently large for the installation of a hoist that will permit of continuing the shaft to deeper levels. Cross-cutting toward the vein is under way and should cut the vein at a point 52 ft. from the bottom of the shaft. The formation exposed in the cross-cut shows greater schistosity than in the vicinity of the vein, on the upper levels, and indicates that the shear-zone is particularly strong at this depth. When reached, the vein will be driven on both ways to explore the ground underlying the workings on the Vipond side and that lying south of the main shaft on the North Thompson side.

Since the beginning of the year stoping has been confined to the 200 and 400-ft. levels. At the 200-ft. level the vein in the stope has increased in width from 5 to 6½ ft. and the value from \$7.50 to \$9 per ton. This stope is being lengthened and timbered. The stope on the 400-ft. level has been timbered for 280 ft., and has reached a point 52 ft. above the drift. The average width of the vein for the entire length as far as opened is 12 ft., with places up to 20 ft. The average value at this point is around \$10 to the ton. A total of 545 ft. of stoping has been done on the various levels to date.

The breaking up of the ice in the Mattagami river has caused a shortage of power, which materially retarded operations at the mine from the middle of March until April 1. It is understood that power is now available.

The tonnage treated from January 1 to March 17 amounted to 6890 tons, an average of 94 tons per day. The gross produc-

tion during that period was \$48,996.20, an average recovery of \$7 per ton milled. Extraction has approximated 90% of the total gold content of the ore. Of the ore milled approximately 5000 tons was broken from the backs of the drifts preparatory to opening stopes. This ore contained considerable waste which it was impossible to segregate. Recently the tonnage going to the mill has averaged \$10 to the ton and has been drawn entirely from the stopes. The difficulties in treating the carbonaceous schist that occurs in some of the ore has been overcome, and from now on a minimum of 100 tons daily will be treated.

The Ingersoll-Rand compressor (1083 cu. ft. capacity) has been received and the foundations for it, and the motor, are in the course of preparation. The motor for this unit will not be shipped until about April 20, and the compressor will temporarily be driven by the 150-hp. motor that is now running the Vipond compressor. This will permit of the employment of 9 machines underground as against 6 at present. The new transformer-house is practically ready for one of the transformer-sets now in use at the old Vipond plant. The completion of the above work will centralize operations considerably, and reduce overhead expenses.

Porcupine, April 10.

COSTA RICA

The mineral resources of the Pacific slope of Costa Rica are important, says the *Bulletin* of the Pan-American Union. Gold has been mined at intervals since before the Spanish conquest. The value of gold exported in 1915 was \$800,294. A small amount of silver (value \$6122) was also exported. Recently a large manganese field was discovered and numerous claims have been located. This orebody is remote from transportation facilities, and occurs in a blanket-formation. Many other minerals are known to exist, but development awaits the coming of additional railways.

Oil has recently been discovered in Costa Rica, apparently in paying quantities. A concession to explore the oil-bearing lands, which are located in San Jose, Guanacaste, and Alajuela, was recently given to an American syndicate. A company will be formed to fully exploit the possibilities of the field.

JAPAN

The Furukawa Co., at its Ashio smelter is installing a Cottrell electrical precipitation-plant. Also a similar plant is being put in the Asano Cement Company.

WESTERN AUSTRALIA

The South Kalgurli Consolidated (Ltd.) reports for February that 8619 tons was crushed, producing 1973 oz. gold having a value of \$8345. Working costs were £9958, leaving a deficit of £1613.

The Ivanhoe Gold Corporation reports the return for January, as follows:

	Gold, oz.
19,510 tons of ore crushed, yielded	2,591
(100-stamp mill running 27 days 13 hours)	
9,084 tons of sand treated, yielded	1,088
8,793 tons of slime treated, yielded	2,542
1,633 tons of concentrate treated, yielded	1,374
Total yield	7,595
Value	£32,243
Average value of yield, per ton.....	33s.
Estimated profit for the month	£9,003

VILLAGE DEEP, LIMITED

The Village Deep, Ltd., for the year ended December 31, 1916, reports: Ore received from the mine, 179,184 tons. Waste sorted out, 13.7%; crushed, 156,700 tons. Number of stamps operated, 180; number of tube-mills operated, 7; mill yield per ton, 4.85 dwt.; assay value of pulp, 2.571 dwt.; total yield, 54,842 fine oz.; total yield per ton, 7 pennyweights.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

COREY C. BRAYTON is at Butte.

MORTON WEBBER is at Oroville.

T. W. MATHER has gone to Dutch Guiana.

G. C. BATEMAN has returned to Toronto from Arizona.

N. M. MUIR will be in Kansas and Oklahoma for the next two months.

HENRY BRINGS, formerly at El Paso, has come to San Francisco.

A. J. UNDERWOOD is now manager of the Lluvia de Oro mines, in Chihuahua, Mexico.

A. P. BUSEY, JR., manager for the Penn Chemical Co., was in San Francisco last week.

JOHN L. HENRY is manager for the Leviathan Copper System in Alpine county, California.

JAMES M. HYDE is at Butte, in connection with the new flotation suit, now in course of trial.

S. S. Fowler passed through San Francisco on his return from San Diego to Nelson, B. C.

DRUMMOND MACGAVIN is here from Toronto, intending to join the Engineer Corps of the Army.

WILLIAM C. MADGE will sail from Victoria, B. C., on May 10, on his way to the Ridder mine, in Siberia.

G. M. SWINDELL, secretary of the Chamber of Mines and Oil, has returned to Los Angeles from Sacramento.

ANDREW M. TWEEDY is resident manager of the Zaruma mines in Ecuador and L. O. KELLOGG is superintendent.

E. H. ROBIE, metallurgist at the Cliff mine, Sudbury, was in San Francisco on his way from Arizona to New York.

WALTER ARNSTEIN has been appointed manager of the Bully Hill group of copper mines, in Shasta county, California.

H. H. NICHOLSON has been appointed general superintendent for the Plinco Copper M. & M. Co., in Plumas county, California.

FRANCIS S. SCHIMERKA, who has had charge of the leaching department of the Shannon Copper Co., at Clifton, Arizona, has resigned.

HENRY N. THOMSON has resigned as metallurgist with United Verde Copper Co. and is engaged in consulting practice at 918 South Kingsley drive, Los Angeles.

Obituary

BERTRAM C. BELL was killed April 15 by being caught in the machinery of the cyanide annex of the Argonaut mill, which is operated by Simonds & Latham. He was a graduate of the mining college of the University of California of the class of 1913, and had been employed at the plant but a month. He had previously been in the employ of Simonds & Latham in their cyanide plant at the Melones mine, in Calaveras county.

EARL C. BACON died on Monday, April 9, at his home in North Salem, New York, after a short illness. Mr. Baker was an engineer of recognized ability. He was a pioneer in the development of hoisting-engines in the United States, and it was he who first placed in operation in New York city the new familiar engine for hoisting materials in buildings under construction. Also he designed and superintended the building of the first asbestos mill in Canada, and was consulting engineer for a number of important mines.

THE METAL MARKET

METAL PRICES

San Francisco, April 24

Antimony, cents per pound	23
Electrolytic copper, cents per pound	37
Pig lead, cents per pound	9.25-10.25
Platinum, soft and hard metal, per ounce	\$105-111
Quicksilver, per flask of 75 lb.	\$113
Spelter, cents per pound	12
Tin, cents per pound	55
Zinc-dust, cents per pound	19-20

ORE PRICES

San Francisco, April 24

Antimony, 50% metal, per unit	\$1.80
Chrome, 40% and over, f.o.b. cars California, cents per unit	50-55
Magnetite, crude, per ton	\$8.00-12.00
Tungsten, 60% WO ₃ , per unit	18.00-20.00
Molybdenite, per unit for MoS ₂ contained	40.00
Manganese, 50% (under 35% metal not desired), cents, unit	37-44
Manganese ore, 40 to 45%, sells f.o.b. Chicago at 58c. per unit with a penalty of 50c. per unit for more than 8% silica.	

EASTERN METAL MARKET

(By wire from New York)

April 24—Copper is weak and quotations are nominal. Lead is firm at 9.40 to 9.50c. Zinc is weak and somewhat lower, at 9.50. Platinum remains unchanged at \$105 to \$111.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. Prices, in dollars per flask of 75 pounds:

Date	1915	1916	1917
Apr. 27	120.00	120.00	115.00
Apr. 3	115.00	115.00	113.00

Monthly Averages

	1915	1916	1917	1915	1916	1917
Jan.	51.90	222.00	81.00	July	95.00	81.20
Feb.	60.23	42.00	126.25	Aug.	93.75	74.50
Mch.	78.00	219.00	113.75	Sept.	91.00	75.00
Apr.	77.50	141.60	113.75	Oct.	93.00	73.20
May	75.00	90.00	101.50	Nov.	101.50	79.20
June	90.00	74.70	101.50	Dec.	123.00	80.00

Considerable business has been done during the past week, during which the quotation fluctuated from \$115 to \$120, the latter figure being maintained today, though quantities are obtainable at a concession from this latter price. Of course, the price quoted is for Californian virgin, and other grades are only accepted at a concession from these prices.

TUNGSTEN

The meeting of the tungsten producers of the United States has brought to light the fact that the present demand for tungsten ore is considerable. That in order to meet this demand by home production, it is necessary to advance the price, thus bringing into the market again ores which would not pay to be mined at the lower figure. Shipping conditions make a reliance upon foreign importation absolutely impossible and the scarcity of freight room has already reduced the imports to a large extent. January statistics showed imports over 600 tons from all sources. February showed only about 350 tons, and it is doubtful whether the March arrivals will exceed 200 tons. The imports from South America, especially Argentine, have stopped or have been heavily reduced, partly on account of the shortage of shipping space, and partly on account of contracts made by the allied governments from South America to Europe. This, and the heavy sales made during the first three months of this year, fully justify an advance, and the Atolia Mining Company of California, no doubt the biggest producer in this country, has adopted a schedule to come into force on May 1, fixing the price for 60% scheelite at \$20 per unit with 30c. variation up and down. No doubt the other producers of the United States will follow this policy. Of course, it must be clearly understood that this schedule applies to good-class ore, especially foreign ores, that generally contain tin and copper, which are most objectionable impurities, that is now sold at a discount from the high grade. \$18 has been paid for foreign ores available for immediate delivery and of fairly good quality, but our market is practically bare of supplies. Sellers of ore are now holding for prices from \$18 to \$20, and at these our market is quite strong. The business transacted during the past week has again exceeded several hundred tons in the New York market alone.

ANTIMONY

The spot demand is not quite as pressing, arrivals having taken care of the most urgent requirements and the nominal quotation is 34c., without finding buyers for quantities thereat. Forward antimony is in good demand; 23c. has been paid for February shipment with April shipment offered around 15 to 16c. Needle antimony has realized 13c. for spot and 8 to 9c. for future delivery, according to position. Antimony ore remains as scarce as ever and there has been little business of late.

MANGANESE

The demand continues very strong; 85c. has been paid on the basis of 45%, which would make the 50% manganese about 90%. Chemical ore is quoted from 4 1/2 to 6c. per pound, according to grade.

PLATINUM

The price of platinum remains unchanged at \$105 for the soft unalloyed metal, and \$111 for the hard natural platinum-iridium alloy.

Eastern Metal Market

New York, April 18.

The dominating factor in the non-ferrous metal market is uncertainty as to just how much copper, lead, and zinc the Government, and also its Allies, are to need. Until this is settled, more or less inactivity and dullness will probably prevail.

Copper has developed further weakness and is lower on small buying.

Zinc continues to weaken on offerings by sellers but little business is reported.

Lead is firm with a stiffening tendency.

Tin is strong and a little higher but not active.

Antimony is more plentiful and easier.

In the steel market prices continue to advance, though domestic buying is some lines is less than in March. Buyers in general are more or less perplexed. Wire has been advanced \$6 per ton by a leading independent company, and scrap has gone up in Chicago. Buying of steel rails for the last quarter of 1918 is conspicuous. France has purchased two lots of 20,000 tons each for that delivery, and the Northern Pacific has contracted for 40,000 tons for the same period. The market is strong and most forms of steel are as hard to get as ever.

COPPER

The sale of copper to the Government a few weeks ago at 16.67c. per lb., and the probable further requirements of both our Government and of the Allies, have worked to unsettle the entire market and partly to disorganize it. In the absence of a large demand, and consequently few sales, the sellers in general have been disposed to let the market go. The result has been lower prices, especially the past two or three days. Yesterday spot electrolytic and Lake were both quoted at about 31c. for nearby and April delivery, New York, though this is a nominal quotation. Some, however, would place the quotation higher, one dealer quoting 33c. for spot metal. A fair amount, however, of spot electrolytic was sold yesterday at 31c., New York. On April 17 future metal was quoted as low as 28c., New York. The market in general is lifeless and weak. The explanation is that buyers are waiting until something definite is known regarding the quantities that will be required by both this Government and the Allies. It is generally believed that the latter will secure the copper at the same price as the United States, but the quantity they will need is either large or small, depending on the viewpoint, with nothing definite known. The London quotation for spot electrolytic yesterday was £147, a decline of £4 from last week.

TIN

The proposition of a Government tax of 10c. per lb. on pig-tin came as a distinct surprise on Monday and has been widely discussed in the trade. The consensus of opinion is that while such a tax is possible, it is hardly probable and that it will be rejected by Congress. Such a move is regarded as against the interests of both the trade and the Government, and as likely to bring about an effect opposite to that generally desired economically. While the price of tin cans would hardly be touched, the burden would fall on the tin-plate maker and the tin dealer. The action of the market this week has thus far borne out the trade's diagnosis. There has been no boom, as might be expected, following such an announcement. On Monday a moderate business was done but not as much as was expected—probably 150 tons in all positions—and on Tuesday the market was decidedly quiet, with the bulk of the business done in futures. Nearly all of last week the market was dull with little business done, except on Friday, when about 120 tons was sold, mostly futures, with nearby metal quiet. The

quotation yesterday was 55.25c., New York, for spot Straits. The arrivals up to April 16, inclusive, were 1795 tons, with 2812 tons reported afloat. Tin imports at Pacific Coast points in February were 1,011,705 lb. through San Francisco, and 1,299,954 lb. through Washington, with 30,098,335 lb. remaining in warehouse February 28, 1917. The London quotation yesterday for spot Straits was £217 17s.6d.

LEAD

The market stiffened early this week, after a week of comparative dullness and inactivity. Yesterday the quotation for prompt metal was 9.20c., St. Louis, or 9.40c., New York, a slight advance over the previous days. This firmer tendency is due to the fact that sellers are holding what lead they have until something definite is known regarding the needs of the Government for both the army and navy. Information regarding this is closely held, and the firmer tendency is expected to continue until definite reports are officially known. Some small sales of future metal were made last week at 9c., New York, and of prompt shipment from the West at 9.25c., New York. The London quotation for spot lead yesterday was £30 10s.

ZINC

There is no abatement in the tendency of the market to weaken despite the fact that very little business is being done. Consumers are averse to committing themselves under present conditions and it is believed that very little buying has been done beyond July 1. The declining market is due to offerings by some interests termed 'weak sisters,' any small sale or quotation making the market. Because of the continued weakness in the market the price of zinc ore has receded \$5 per ton, until the quotation is \$65 to \$80 instead of \$70 to \$85, depending on the quality. The quotation yesterday was 9.50c., St. Louis, or 9.75c., New York, for prompt and April prime Western spelter with a possibility that 9.37½c. could be done.

ORES

TUNGSTEN. The action of the producers at their meeting in San Francisco last week in setting an official price, as understood here, of \$20 per unit for concentrate is not favorably regarded. The price is at least \$2 above any sale made in many weeks or months. The fact that a prominent owner of a leading tungsten mining company is also influential in Government War-defence matters is looked upon with some suspicion. Why should tungsten dealers raise their price when copper and steel producers are reducing theirs? Several hundred tons are reported sold in the last week. The quotation here is about \$17 to \$18 per unit, depending on the quality. Ferro-tungsten is obtainable at about \$2 per lb. of contained tungstic acid.

ANTIMONY. The ore is reported very scarce and little business has been done.

MOLYBDENUM. The quotation for wulfenite is from \$2 to \$2.25 per lb., but very little is offered. As to molybdenite, the position is as unsatisfactory as ever. Thirty tons of ferro-molybdenum were cancelled recently on account of the suppliers being unable to get the raw material in time to fill these orders. Whatever ore is coming on the market is paid for at fancy prices and it is hardly possible to speak of a regular market at all. The quotation is \$2.50 to \$2.75 per unit for high-class ore.

MANGANESE. There is a considerable demand for furnace-ore and 80 to 85c. is paid, delivered at smelter on the basis of 50% metallic manganese. Chemical ore (manganese di-oxide) is quoted from 4½ to 6c. per lb. according to grade.

Company Reports

BROKEN HILL SOUTH SILVER MINING CO.

The report for the half year ended December 31, 1916, shows a total production of £452,469, against which the working costs were: ore extraction £135,815; ore treatment £40,172; and mine development £20,691. The balance carried to profit and loss account was therefore £255,789. Additions to plant during the half year cost £17,032. Two dividends were paid amounting to £120,000. The ore hoisted was 157,059 tons, assaying 6.7 oz. silver, 14% lead, and 13.8% zinc. Of the ore sent to the treatment works, 96.1% was broken by contract, 1% was mined on wage, and 2.9% came from mine-development. Development consisted of 1373 ft. of driving, 491 ft. of raises, 179 ft. of shaft, and 3263 ft. of diamond-drill holes. The average number of men employed on the surface was 454 and underground 922. The ore-reserves at the end of 1916, making no allowance for probable ore, amounted to 3,500,000 tons. The products from the concentration plant were as follows:

Product	Net weight, tons	Assay value			Proportion of metal content		
		Lead, %	Zinc, %	Silver, oz.	Lead, %	Zinc, %	Silver, %
Concentrate	27,650	60.6	8.9	21.3	76.2	11.3	55.8
Tailing, zinc	86,737	3.2	16.6	3.1	12.6	66.4	25.5
Tailing, quartz	17,659	1.0	6.4	1.2	0.8	5.2	2.0
Slime	25,414	9.0	14.5	7.0	10.4	17.1	16.7

The first unit of the lead-section of the selective-flotation plant operating on slime ran continuously during the half year. A portion only of the slime was treated at first, but after improvement had been perfected the total slime-product from the concentrator was handled, the result being as shown below:

Product	Net weight, tons	Assay value			Proportion of metal content		
		Lead, %	Zinc, %	Silver, oz.	Lead, %	Zinc, %	Silver, %
Concentrate	1,924	58.7	9.3	44.7	82.8	10.1	88.8
Residue	11,718	2.0	13.6	0.9	17.2	89.9	11.2
Total	13,642	10.0	13.0	7.1	100.0	100.0	100.0

The zinc-section of the selective flotation-plant is completed and experimental work is in progress on the residue from the lead-section. The high calcite-content has rendered it difficult to obtain satisfactory commercial results. The total costs, exclusive of selective flotation, per ton of concentrate produced, were £6 17s.4d.

GOLDFIELD CONSOLIDATED

The annual report of the Goldfield Consolidated Mines Co., for the year ended December 31, 1916, shows that 338,680 tons of ore was milled, having an average assay value of \$7.52 per ton and a gross value of \$2,548,425.83. The loss in tailing was 99 cents per ton, which with smelter discounts gave an actual return of \$2,211,348.18. The net cost was \$1,754,781.42, leaving a realization on operations of \$452,734.05. Expenditure on account was \$24,114.21, leaving a net realization of \$428,619.84, equivalent to \$1.27 per ton of ore milled. Stoping cost of ore milled was \$2.56. Milling cost was \$1.53 per ton of ore treated, plus 34 cents for treatment of concentrate.

NORTH STAR MINES COMPANY

During the year 1916 the gross production of the North Star mine was \$1,160,007; the expenses for current operation amounted to \$613,102, and for development to \$84,303, or a total outlay for operation and development of \$697,405, leaving

a profit of \$462,602. Outlays during the year on account of improvement and property purchase amounted to \$110,307, leaving a balance of \$352,294. Interest and dividends on invested funds amounted to \$37,755, increasing the total net earnings of the year, before deduction of allowance for depreciation and apart from the result of operations at the Champion mines, to the sum of \$390,049. Dividends amounting to \$300,000, 12% on the capital stock, were paid during the year. The output came chiefly from stopes above the 3000, 3400, and 4400-ft. levels. A total of 135,760 tons of rock was mined and delivered to the mills, of which 24,430 tons was sorted as waste in the sorting-plant, leaving 111,330 tons of ore crushed, with an average yield of \$10.42 per ton crushed, at an average cost of \$5.51 per ton for operating and \$0.75 for development expenses, making an aggregate cost of \$6.26 per ton crushed (\$5.12 per ton mined), and leaving a realized profit of \$4.16 per ton crushed. Owing to the employment of water-drills in the mine and the use of water in the process of sorting out the waste rock at the surface, the ore as milled contained about 8% of moisture, a considerably higher percentage than in previous years. It must also be noted, in a comparison of the present yield and costs per ton with those of former

years, that in 1916 about 24,430 tons of rock mined as ore was discarded at the sorting plant as waste, which naturally tended to raise the yield and costs per ton crushed. Of the total production of the year, 80.78% was obtained in the mills by amalgamation, while 19.22% was recovered by cyanidation. It is estimated that the value lost in the tailing was about 35c. per

(wet) ton crushed. The development work amounted to 6384 ft. (drifts 5063 ft., raises 1189 ft., winze 49 ft., and cross-cuts 83 ft.), in the course of which a total of 6826 tons of ore was produced. This work resulted in the opening of profitable ore-bodies, east and west of the shaft, and between the 2700 and 4400-ft. levels, with the addition to the ore reserves of a tonnage exceeding what was extracted from the mine during the year.

AHMEEK MINING COMPANY

The Ahmeek Mining Co. report for the year ended December 31, 1916, contains the following: Gross value of copper produced, 24,142,158 lb., sold at 25.72c. for \$6,210,244.67. Silver sales, \$16,503.60. Interest, \$8742.72. Total income \$6,235,490.99. Running expense at the mine, \$1,699,984.24. Construction account, \$320,833.77; smelting, freight, commissions, and Eastern office, \$764,963.46. Total expense, \$2,785,781.47. Total net returns, \$3,449,709.52. Four dividends were declared during the year, two of \$600,000 each, and two of \$800,000 each, a total of \$2,800,000. There was treated, 1,164,010 tons of ore. The cost per ton of mining, transportation, stamping, and taxes was \$1.46. The operating cost per pound of production of copper was 7.04c. Other items increased the gross cost to 11.54c. From this was deducted the value of silver sold, amounting to 0.07c. per lb. of copper, making the total net cost 11.47 cents per pound.

Recent Patents

1,221,144. PULVERIZING APPARATUS. Joe Crites, Chicago, Ill., assignor to Raymond Brothers Impact Pulverizer Company, Chicago, Ill., a Corporation of Illinois.

1. In pulverizing apparatus, the combination of a pulverizing chamber having a discharge opening and an interior conical surface convergent toward said opening, an impact pulverizing element in said chamber which is revoluble upon and adjustable lengthwise of the axis of said conical surface, and means for producing a draft of air through said chamber longitudinally thereof and in the direction toward said opening.

2. In pulverizing apparatus, the combination of a pulverizing chamber having interior, oppositely inclined, conical surfaces, an impact pulverizing element therein which is revoluble upon and adjustable lengthwise of the axis of said conical surfaces, and means for producing a draft of air longitudinally through said chamber.

1,221,022. METHOD OF EVAPORATING AQUEOUS SOLUTIONS. Raymond U. Bunker, Yonkers, N. Y.

The method of evaporating aqueous solutions in a multiple effect continuous graining pan, which consists in boiling down charges of the material to be concentrated, for instance, maseuite, in the various chambers at different temperatures, passing the vapors step by step through the series of chambers, and advancing the charge from one chamber into another but into that chamber which is at the temperature to which the charge should be subjected for further concentration depending upon the existing stage of its evaporation, said vapors being passed through the chambers in such way that the last of said series of chambers in the order of advance of the charge is in a different relation to the order of progression of the vapors.

1,221,506. PROCESS OF PRODUCING THE BICARBONATE OF AN ALKALI OR ALKALINE-EARTH METAL. John E. Bucher, Coventry, R. I., assignor to Nitrogen Products Company, Providence, R. I.

1. An improved process for producing the bicarbonate of an alkali metal, which comprises reacting upon the chlorid of said metal with a nitrogenous acid carbonate and with an alkali metal compound containing carbon united to nitrogen by a plurality of bonds, to reform said chlorid of said metal

and to form said bicarbonate and a nitrogenous compound which, at the temperature of the operation, is much more soluble than said chlorid of said metal.

2. An improved process for producing the bicarbonate of an alkali metal, which comprises reacting upon the chlorid of said metal with a nitrogenous acid carbonate and with an alkali metal compound containing carbon united to nitrogen by a plurality of bonds, to reform said chlorid of said metal and to form said bicarbonate and a nitrogenous compound which, at the temperature of the operation, is much more soluble than said chlorid of said metal, and separating said chlorid from said soluble nitrogenous compound, in part at least, by crystallization of one of said last two mentioned substances.

1,212,932. FILTERING APPARATUS. Albert Legrand Genter, Salt Lake City, Utah, assignor to Kelly Filter Press Company, Salt Lake City, Utah.

In a filtering apparatus of the character described, the combination with a shell or casing and a carrier slidably mounted relatively thereto, and provided with filter leaves and a central hollow shaft which communicates with the interior of said leaves, of a driving shaft entering one end of the shell or casing, and clutch members on the opposed ends of said shafts adapted to operatively engage substantially simultaneously with the seating of the carrier within the shell or casing.

1,221,045. CONDENSER FOR REDISTILLING SPELTER. John G. Granberg, Beckmeyer, Ill.

In combination with a retort, a condenser having at its retort end a fixed bridge and a downturned flange arranged to prevent leakage between the abutting ends of the retort and the condenser, and said condenser having a fixed head at its drawing end provided with a drawing opening and a charging opening.

1,215,544. PROCESS OF RECOVERING POTASSIUM CHLORID FROM ALKALINE DEPOSITS. Louis C. Jones and Fred L. Grover, Syracuse, N. Y., assignors to The Solvay Process Company, Solvay, N. Y.

1. The process of recovering potassium chlorid from alkaline brines containing sodium carbonate which consists in concentrating the brine at a high temperature, then filtering out the precipitated less soluble sodium salts leaving potassium chlorid and the boric acid content of the brine in solution and finally cooling so as to precipitate only potassium chlorid while leaving the boric acid content of the brine in solution to be subsequently recovered.

5. The process of recovering potassium chlorid from alkaline brines containing sodium carbonate which consists in heating and concentrating the brine so as to convert boric acid and boric acid salts present into more soluble sodium metaborate and precipitate less soluble sodium salts while leaving the

potassium content of the brine in solution and continuing the concentration until the solution is saturated with potassium chlorid at the temperature employed, removing the precipitated sodium salts and then cooling to precipitate potassium chlorid leaving sodium metaborate in solution, returning the mother liquor to the succeeding batch of brine and repeating the operation until the mother liquor approaches saturation in sodium metaborate, then precipitating sodium metaborate as borax and again returning the mother liquor to the brine to effect further recovery of potassium chlorid.

1,212,199. METHOD OF REMOVING SULFUR DIOXID FROM METALLURGICAL SMOKE AND SIMILAR GASES. Frederick Augustus Eustis, Milton, Mass.

The method herein described of removing sulfur dioxide from metallurgical smoke and similar gases which contain small amounts of sulfur dioxide, said method consisting in passing through a flowing body of said gases a copious flow of water containing, in solution, a material adapted to promote absorption of sulfur dioxide, said water being sufficient in quantity as compared to the volume of gas, to cause with the aid of the absorbent a physical solution of the sulfur dioxide gas in the liquid.

1,215,636. PROCESS FOR TREATING ORES. Arthur S. Dwight, New York, N. Y., assignor to Dwight & Lloyd Sintering Company, New York, N. Y.

1. The herein described method of treating sulfid ore for the obtaining therefrom of gas charged highly with sulfur and simultaneously obtaining a uniformly porous sinter, the same consisting in exposing the sulfid ore in a relatively shallow layer or stratum, passing air therethrough and causing combustion therein, collecting said air after passing through the ore and while containing a relatively low percentage of sulfur, causing the said combustion to form a uniformly porous sinter body, then passing the said air with its sulfur contents again through the sintered ore and oxidizing more or less of the sulfur residue therein, charging the air volume with the sulfur gases derived therefrom.

1,208,334. CONCENTRATION OF ORES. Henry Lavers, Cambridge, Henry Howard Greenway, Melbourne, and Alfred Henry Piper Lowry, Prahran, Victoria, Australia, assignors to Minerals Separation American Syndicate (1913) Limited,

London, England. Original application filed Mar. 14, 1914, Serial No. 824,765. Divided and this application filed Sept. 14, 1916. Serial No. 120,057.

1. A process of concentrating ores which consists in agitating and aerating an ore pulp containing in solution an alkaline substance, but without the addition of a frothing agent other than the said alkaline substance, so as to obtain a froth of concentrates, and separating the froth.

1,215,672. PROCESS FOR TREATING METALLIFEROUS ORES. Richard Lewis Lloyd, New York, N. Y., assignor to Dwight & Lloyd Metallurgical Company, New York, N. Y.

1. The herein described process for treating metalliferous ores in fine condition, which consists in projecting a stream of the ore fines into a confined chamber, subjecting the scattered particles to a high heat thereby causing initial chemical reactions therein then while in a highly heated and nascent state suddenly arresting said particles while being driven by the force of projection and before reaching the chamber exit and causing them to mass together to form relatively small accretional bodies wherein incipient smelting action occurs, and then collecting the said bodies in a smelting bath, substantially as set forth.

1,215,988. ORE-SAMPLER. Frank B. Pott, Leadville, Colo.

1. An ore sampler, comprising a revoluble drum open at one end and mounted on a horizontal axis, a cone arranged centrally within the said drum and rotatable with the same, the apex end of the cone leading to the open end of the said drum, buckets arranged peripherally on the said drum and opening onto the base end of the said cone, and means for delivering the material to be sampled into the buckets at the time the buckets reach an uppermost position, whereby a portion of the material of each bucket will slide down the cone to the open end of the drum and the portion remaining in the bucket discharged therefrom when the bucket reaches its lowermost position.

1,212,130. FLOTATION PROCESS OF CONCENTRATING. Galen H. Clevenger, Palo Alto, Cal. Filed June 13, 1916. Serial No. 103,558.

1. The method of concentrating ores which consists in distilling sage and utilizing the liquid products of the distillation as flotative agents in the flotation process of concentrating ores.

2. The method of concentrating ores which consists in destructively distilling sage and utilizing the liquid products of the distillation as flotative agents in the flotation process.

Mining Decisions

MINING CLAIMS—MEANDERED BOUNDARIES

Plats and field notes referred to in patents may be resorted to for the purpose of determining the limits of the areas that passed under the patents. Reference in a patent to the mineral lot number of the claim is sufficient reference to the plat and the field notes to render them admissible to show that the lines of such claim bordering on a water front are in fact meander lines. A meander line is a line run in the survey of particular portions of the public domain bordering on a stream or other body of water, not as a boundary of the tract surveyed, but for the purpose of defining the sinuosities of the bank of a shore of the water and as a means of ascertaining the quantity of land within the surveyed area subject to sale. This rule of meander lines is applicable to mining claims abutting on a navigable body of water. Where one of the boundaries of such a claim is a navigable body of water all accretions formed after the survey and prior to entry and patent of the claim passed under the patent, and all accretions that may thereafter form become the property of the riparian proprietor.

Alaska United Gold Mining Co. v. Cincinnati-Alaska Mining Co. (Land Department), 45 Land Decisions, 330. April 18, 1916.

• NATURAL GAS CONTRACT—CONSTRUCTION

Held, that under a contract to purchase "Merchantable" gas from natural gas well owners, gas which gave only 500 to 550 British thermal units of heat was not "merchantable" where the standard gas sold in the same locality contained 1000 B.T.U's.

Ely v. Wichita Natural Gas Co. (Kansas), 161 Pacific, 649. December 9, 1916.

RAILROAD GRANT—MINERAL EXCEPTION CLAUSE

Land upon which there is no present indication of mineral nor any geological evidence that would warrant a mineral finding, should not be held mineral in character and excepted from a railroad grant merely on the premise that future prospecting might disclose evidences of mineral.

Southern Pacific Railroad Co. (Land Department), 45 Land Decisions, 327. August 31, 1916.

MINING REGULATIONS FOR ALASKA

The recently amended regulations affecting mineral patents in the Territory of Alaska will be found in 45 Land Decisions, 256, under date of July 19, 1916. The Regulations governing Coal and Land leases in Alaska are published in the same volume at page 287.

INFUSORIAL EARTH HELD A "VALUABLE" MINERAL DEPOSIT

Lands containing deposits of diatomaceous or infusorial earth in such quantity and of such quality as to be commercially valuable therefor, are mineral lands and are to be considered as excepted from railroad grants.

Central-Pacific Railway Co. (Land Department), 45 Land Decisions, 223. July 13, 1916.

The Auto-Truck in Mining

Nothing has done so much to advance the development of the isolated mining regions of the West as the auto-truck. Where formerly wagons, drawn by horses and mules, moved slowly across heavy sandy roads of the desert or through the rocky mountain passes, the auto-truck now runs, dragging its trail-wagons loaded with ore, or other minerals, to the nearest railroad, or takes heavy machinery to the mines. The cost of operation is generally far below the cost of freighting by the old mule and bull-trains. The picturesque prairie-schooner

A WHITE AUTO-TRUCK CROSSING CONTINENTAL DIVIDE, IN MONTANA.

with its humorously profane mule-skinner or bull-whacker has passed into history. The West owes much to them—it could never have been developed without them—but the auto-truck has displaced them, performing the service more quickly, more cheaply, and in every way more satisfactorily.

The accompanying illustration shows a White Good-Roads auto-truck hauling ore over the Continental Divide in Montana. The scene, offset by the ditch and flume, and the stumps of a de-forested area, is typical of many places in the West.

THE GEOLOGIC FORMATIONS OF CALIFORNIA. By J. P. Smith. Pp. 47. California State Mining Bureau. Price 25 cents. This little volume has been issued as Bulletin 72 of the State Mining Bureau, and is a useful contribution to the geological literature of the State of California. It contains a carefully compiled bibliography of the subject, and a brief résumé of the present knowledge of the distribution of the geological formations of the State. It has been published as a text to accompany the geological map of California, recently issued, and referred to at the time in these columns. The bulletin is sold separately.

EDITORIAL

T. A. RICKARD, Editor

ACCORDING to *The Annalist*, the index-number expressing the cost of living has now risen to 270, as compared with 166 a year ago. In 1896 it was 80. Patriotism and self-interest alike call for personal thrift.

GERMAN jibes that for us this is 'a dollar war' and that we are unable to take an effective part in warfare are being answered. The whole-hearted effort now being made to assist the Allies speaks for itself; as to the naval and military participation, that will follow in due course.

LINOLEUM manufacture is just being started on the Pacific Coast by the Paraffine Paint Company. This involves an important consumption of zinc oxide and sulphate, lithophone, talc, and paris white, and is consequently of great interest to many producers of minerals and metallic salts.

JOURNALISM has found patriotic expression in a tender of service to the Government, no less than 277 technical and trade papers having offered editorial co-operation and free advertising space to support the work of the Administration in connection with the War. As would be expected, this paper is one of them.

MINES will have to do their share in finding money for the War. In the budget of the Union Government of South Africa it is proposed to impose a tax of 5% on the incomes of mining companies, together with a dividend tax of 7½% on gold and diamond companies. This taxation will replace the former 10% profit-tax, so that it does not seem inequitable.

TOYOKICHI IYENAGA, addressing the American Academy of Social and Political Science at Philadelphia on April 21, said, "The problems of a durable peace between America and Japan will not have received their definite and final solution until Japanese residing in this country receive full recognition of their political and social equality with people of other nationalities."

LAST week we referred to the dangerously deceptive character of the slogan 'Business as Usual' at this time of national crisis. We note an editorial heading in that pestilential paper *The Examiner* to the same pernicious effect. Mr. Hearst says in big type "If We Do Not Prepare for War Now by Universal Service, What Shall We Do if Real War Comes?" "Real war," forsooth: what is this if it be not a real war; is it a newspaper war to be waged by a disreputable press to fill its pages with sensational items? No, indeed, it is a stern

reality; it is a war for the right to live and let live, for democratic ideals, and human freedom from an unscrupulous campaign of aggression. The United States is at war with Germany; when two such nations face each other, even with an ocean between them, it means one of the biggest and bitterest wars in history.

MR. HOOVER has given a valuable piece of advice: the centralization and co-ordination of benevolent work, for the purposes of the War, in the hands of the Red Cross. He states that the overlapping efforts, multiplication of committees, production of useless material, and the like, have led to a pitiful waste of endeavor in every European country and also in neutral territories. He advises that all local organizations should get in touch with the executive of the Red Cross immediately.

CYANIDE is being supplied from Glasgow to the Canadian mines for 15 cents per pound, according to Mr. Arthur A. Cole, the President of the Canadian Mining Institute, while on this side mining companies have to pay anything from 30 cents to \$1.30 per pound. The British government made an arrangement early in the War whereby the Cassel Cyanide Company was to supply cyanide to mines within the British empire for 18 cents during the first eight months, then for a year at 16 cents, and thereafter at 15 cents per pound. Why should not our Government take similar steps to aid the mining industry of the United States by making an arrangement with the Roessler & Hasslach Chemical Company whereby our mines also would obtain cyanide for a reasonable price. If cyanide can be supplied from Glasgow to Ontario at 15 cents, why can it not be supplied from New Jersey to Nevada and California at something like the same cost? Would it not be possible for our ally, Great Britain, to do us the favor of assisting us in this relatively small matter, by way of recognition of the solidarity of interest now subsisting between the two nations?

MANGANESE ores in 1913 sold at prices ranging from \$7 to \$12 per ton. The higher figure represents ores of superior purity containing about 50% of the metal. The present price for ore of equivalent grade is about \$29 per ton. Owing to the decline in domestic resources attention is being directed to the recovery of the manganese in the slags from bessemer and open-hearth converters. Acid open-hearth slags contain from 3 to 21% of manganese di-oxide, and for some time such slags have been regularly sold to makers of ferro-manganese. During the War the scarcity of manganese in Sweden and Germany has led to the utilization of this

material that formerly had been neglected, the richer slags being reduced with charcoal in the electric furnace. The leaner basic slags are charged into blast-furnaces as part of the regular burden. The latter practice will probably become general in the United States, and will effect a recovery of metallic manganese estimated at nearly 30,000 tons yearly.

CHILE has threatened to levy an export duty upon copper, and Bolivia upon tin. This is an example of the familiar game of national aggrandizement. It strikes the world differently when the game is played by a small nation instead of a great one, though of course it should not. Chile is within her legal rights in seeking the main chance, but it must be followed warily. The hunter must keep to windward of the deer. Capital is timid and may take flight if bungling methods be used. Copper is not confined to Chile; the likelihood of new discoveries and fortunate development in our country has by no means passed away. It would seem that Chile had more to gain by developing domestic industry than by limiting it. Her resources are just coming to be widely known, and foreign investors have shown a willingness in recent years to undertake mammoth operations under the protection of her laws, but an export duty will deter new ventures. Even Bolivia might well consider whether the tax receipts from a constantly expanding mining industry, together with the wages paid, and the duties collected on a growing import trade, were not of more avail for purposes of revenue than an impost upon one of her principal products. By its nature an export-tax restrains foreign aid in opening a country's resources, and it either hinders the article taxed from being shipped abroad, or requires the selection of a higher grade of ore in order to meet the increased exactions of the government. At best an export-tax is unfortunate. It savors of restriction, and makes a different appeal to the imagination than a levy upon income. Unless there is a domestic demand it operates in the direction of stagnation of industry, and in both the cases cited no such internal demand exists.

CURVES of metal-prices before and during the War, plotted and published by the *Steel and Metal Digest*, tell an interesting story. The depression in the market is shown by steadily declining curves for the year preceding the outbreak of hostilities. The doleful prophecies of financial disaster, so general at that time, are reflected most conspicuously in the curves of copper and lead; copper especially plunged headlong downward. It is evident, on the other hand, that there were men in control of the other metals who had either an inspiration or a knowledge of the impending needs of a martial world. Zinc made a sharp but feeble gain in the early days of the War, as did aluminum also, while antimony and tin leaped within a week to more than double their former price. In the case of tin the cause lay in the fear that the Suez Canal might be closed, and the danger menacing vessels sailing from Nigeria and the Straits, this fear being intensified by the actual sinking of cargoes

of tin concentrate by the German raider 'Emden.' Antimony was subject to frequent violent fluctuations, partly because the output is restricted and largely localized in China; the increase here was the result of a shortage of immediately available supply, due in part to the British embargo. The period of wild speculation is registered by high points on all the metal curves during the summer of 1915; since then steadying influences, indicative of a more rational commercialization of the war-demand, are conspicuous. Only copper and aluminum have shown a constant advance into the present year. Aluminum owes its position to its increased use in the manufacture of explosives, notably 'ammonal,' while the high copper prices may reflect a growing confidence on the part of the producers, stimulated by speculators, some of whom have quite freely expressed the optimistic opinion that the period of re-construction after the War would sustain demand near its present level.

An Experiment in Technical Education

Industrial mining-schools offer a solution of a pressing educational problem in this country. An innovation in providing instruction of a lower grade than that given at the universities is discussed elsewhere in this issue in an interesting and suggestive communication from Mr. Francis Church Lincoln, Director of the Mackay School of Mines at Reno, Nevada. That State has ventured to play the part of pioneer in this educational field, and the plan developed is wider than mere university-extension work. It may prove to be even wider than the sponsors of the system in Nevada have as yet undertaken to suggest. Just what it signifies is perhaps indicated by the action of the Columbia School of Mines over a year ago when the requirements for admission were raised, following the adoption of a five-year course leading to a degree. This advanced position is in harmony with the historic policy of that institution: culture, in its popular and broader sense, has not been overshadowed there by the technical requirements of the engineer. The broadly educated technologist everywhere has become foremost in his profession, whether it be mining, or chemistry, or electricity. With breadth of culture comes breadth of mental vision and such a knowledge of man as helps to the understanding of men. It gives masterful qualities that the untrained mind attains but rarely, and then only through a dominant mentality that would have lifted the individual to eminence from any station. To count upon the saving grace of native talent, to eschew the advantages of instruction in the humanities, because, in a country not yet completely emerged from its pioneer ruggedness of character, shining examples of success without these aids are still conspicuous, has long been the peculiar error of our young men, to which the universities have too readily yielded. It has been said that the American technical colleges have been turning out graduates who were neither trained engineers nor skilled artisans. This cannot be said of Columbia or of Harvard, and never will be, because they have set clearly before

themselves the ideal of being the intellectual parents of engineers destined to become the leaders of industrial development. Other mining-schools have been alert to the impending change, so that there has followed a notable stiffening of educational standards; but they have been hampered by the conditions under which the narrower training had been developed. Only a beginning has been made in the reaction against the lowered standards that began some thirty years ago, before the old academic faculties had seen how to make peace with the champions of practical science. In the struggle between 'town and gown,' the town always wins at first, but the factions ultimately discover the value of friendly co-operation. The system of industrial technical schools, now extended to embrace the field of mining, offers a convenient way out of the difficulty. The regular mining-schools have long been forced to meet the demands of young men unfortunately lacking in the fundamental necessary preparation for a sound scientific training; they have also met a demand for brief courses intended as a short-cut to jobs requiring a rudimentary knowledge of chemistry, electricity, and mechanics. The faculty of every school of this character has had occasion to blush at the discovery that these concessions had been abused by men posing as graduates after having taken no more than an elementary course of a few months' duration. The colleges have been cheapened by it and the standing of their graduates has suffered. The evil will persist as long as these shorter courses are given within the college-halls. The industrial school, however, maintained apart from the university, covers the need and does it effectively, offering the advantages to a larger number of men than can be reached by the other system, and protecting the graduated engineer from the cheapening of his diploma. Moreover, the school that is frankly technical, and nothing more, fully meets the requirements of those who are not prepared for the broader scientific and highly cultural courses. The Nevadan plan is capable of general adaptation and must commend itself to other communities.

A Captain of Industry

Some of the great mines of the world are so closely identified with the men that made them that the mine becomes a monument to the fame of the man. Thus Dolcoath unfailingly recalls Capt. Josiah Thomas, the St. John del Rey is associated with George Chalmers, and the Copper Queen with the honored name of James Douglas. Another great copper mine, the greatest copper mine developed to date, is the Utah, which similarly is linked to the name and reputation of Daniel C. Jackling. In this issue we publish an interview with that engineer, whose wealth and success have subjected him to the penalty of being labeled, in the daily press, as a 'copper king' and a 'metal magnate.' To the readers of this paper he is more than that; he is an exponent of American initiative and resourcefulness of the most effective type; he represents the man that can do big things in a big way. Looming large in the public interest he is

one concerning whom our readers will like to know by what means and by what technical advantages he became prepared for his remarkable career and to what extent good fortune is responsible for his extraordinary success. Therefore we have interviewed him, asking the questions that would be likely to disclose what manner of man he is. The interview tells that unmistakably. In the first place, he emerged from an uninteresting environment, although his forebears were worthy people and of good stock; but a farm in Missouri is not an incubator congenial to engineering talent of a high order. An orphan while yet an infant, he lost something that no kind relative could replace. His schooling appears to have been of a desultory kind, and his boyhood wanting in opportunities that would be likely to prepare him to play a leading part in big affairs; however, he showed early intelligence in noting the usefulness of education and in figuring how to make enough money to be independent. That is a good democratic idea: the wish not to be dependent, to make enough money not to have to truckle to anybody, to be able to look any man in the face, and, if necessary, to tell him—what you think. His real instruction began late; he was 19 when he started to school regularly and 20 when he entered the School of Mines at Rolla. He tells us how the idea of engineering came to him while watching a surveyor at work; the precision of it captivated him. So he went to Rolla and there placed his foot on the first rung of a ladder that led to individual effectiveness. At that time he was poor, dependent on the little money earned during vacations, supplemented by such financial assistance as a kindly aunt was able to afford. He worked his way through college. That is a statement true of several distinguished engineers, for example, H. C. Hoover and F. W. Bradley. It is a fine thing to say of any man. Mr. Jackling worked on a railroad during his vacations and then won an appointment as instructor in the Missouri School of Mines, so that he was able to obtain his degree, which he did in a year less than the usual length of time. Already there was evidence of mental power; also of a restless spirit, for he changed his mind several times as to the choice of a career before he selected metallurgy. Just then Cripple Creek was on the boom; he read about it and decided to go thither. His funds were so scanty that he had to walk the last 18 miles of his journey, arriving at Cripple Creek with \$3 in his pocket. There must be great satisfaction in this retrospect to a man that now could buy a railroad. Indeed the taste of poverty and the stimulus imparted by eager necessity are powerful factors in shaping strong character. An assay-office gave him his first start and a man named Staats, whom we also remember, as we do our meeting at that time with the young assayer who was destined to become the great exponent of big-scale copper mining. Then came a bit of good luck. Mr. Jackling's career was affected profoundly by the acquaintance he formed, at Cripple Creek, with Messrs. Charles M. MacNeill and Albert F. Holden. While serving his metallurgical apprenticeship at the old Lawrence mill he made friends of these resourceful

men. At that time Capt. Joseph R. De Lamar, one of the most picturesque characters in American mining, had noted the keen intelligence of the young metallurgist and asked him to make experiments on the complex ore then being mined at Mercur. That gave young Jackling the chance to investigate various processes, and prepared him for his later work at Mercur, where he won his spurs as a metallurgist. There also he got on the track of bigger game. Capt. De Lamar and Mr. MacNeill were two links in the causation that led to the Utah Copper. In 1898 the group of claims in Bingham canyon then controlled by Colonel E. A. Wall were offered to Capt. De Lamar as affording an opportunity for exploiting a large body of low-grade gold ore by cyanidation. The samples sent to Mercur showed that the gold content was less important than the copper, but the percentage of the latter was too low to be attractive at that time. However, Mr. Jackling, who had charge of the drilling of the ground, and made the necessary metallurgical tests, reported to De Lamar in 1899 that there existed an immense body of low-grade copper ore that could be exploited profitably if the operations were conducted on an adequately large scale. The spending of \$3,000,000 preparatory to treating 2500 tons of 2% copper ore per day seemed, at that time, anything but attractive, even to such an enterprising man as De Lamar. So the project was dropped by him, but not by Mr. Jackling, whose ideas of opening up a big thing at Bingham were strengthened by the favorable opinion of Mr. R. C. Gemmell, who assisted him in his first examination of the property and is now the general manager of the great enterprise that resulted therefrom. But the result was not achieved either quickly or easily. Mr. Jackling went back to Colorado, being employed as consulting engineer by his old friend Mr. MacNeill, who had become associated with Messrs. Spencer Penrose and Charles L. Tutt in organizing several important metallurgical plants. By this time Mr. MacNeill had become a capitalist and had won a following among moneyed people at Boston and New York. To him Mr. Jackling brought his vision of a big copper enterprise at Bingham, supplementing his idea with facts and figures of a kind that were convincing to his friend, who knew him to be no crazy optimist but an engineer with a disciplined imagination. Through Mr. Hartwig Cohen, De Lamar's manager, Mr. Jackling was enabled at last, in 1903, to obtain an option on the property from Colonel Wall. Mr. MacNeill took the business in hand; an independent examination of the prospective mine was made by Mr. F. H. Minard; the ground was sampled on a large scale and the assays confirmed the figures obtained by Mr. Jackling himself in 1898. Thereupon enough money was raised to build an experimental plant at Bingham. On a 2% ore a 70% recovery in a 25% concentrate was obtained. The experimental mill and the preliminary operations more than paid their way, so that the mill was gradually enlarged to a daily capacity of 1000 tons. Mr. Jackling's judgment was verified, the project was placed well on its feet, the necessary capital was obtained for a steady expansion

of operations, but just after the new concentrating plant, of 6000 tons capacity, was started the enterprise received a dangerous shock from the financial panic that paralyzed American industry near the end of 1907. Mr. Jackling does not say much about that in the interview, but it was a bad moment for the Utah Copper Company. A number of his associates were 'long' on large blocks of the stock and he himself was not in an invulnerable position; but he aided them and was able to protect himself, leaving a pleasant memory of forceful ability in a time of crisis and of personal loyalty to friends. That experience, and others, have established a feeling of comradeship that has proved a powerful aid to his administration of the several big enterprises of which he is the managing director. He has created an organization that is cemented by loyalty. Bluff, blunt, and big-hearted, he loves work for its own sake, he likes to be doing something interesting, he is willing to take chances, and is ambitious to wield power. Congenitally a speculator as well as an engineer, he enjoys an enviable reputation for truthfulness and for straight dealing in business transactions. To his administration of big affairs he applies a mind that is adaptable to new problems and shows ability to remember intricate details easily; and he knows when he makes a mistake—that is a saving grace lacking in many successful men. His frank acknowledgement of the miscalculation at Juneau is peculiarly instructive and disarming. He was drawn into that affair through the late Albert Holden, a daring speculator and a man of remarkable initiative. Mr. Jackling thought he could apply the big-scale copper methods to a large low-grade gold deposit, and he succeeded up to the point where one factor went wrong, namely, the estimation of the average tenor of the ore. The big sample—375,000 tons—broken in the Perseverance mine by the old company, and the milling of other large tonnages from later development-work, failed to give a true average. The yield proved less than anticipated, so that, although the estimate of cost was fully confirmed, the net result was disappointing. Mr. Jackling discusses the matter frankly and clearly. Many will find this the most interesting part of the interview. It shows that he is not so spoiled by fortune as to be unable to learn. Only 47, he will yet accomplish more. A farm-laborer at 18 and a millionaire at 40, he maintains a keen interest in the metallurgical operations by which he found a way to distinction in the profession. Today he directs the exploitation of a group of mines that will produce 600,000,000 tons of copper ore in the next 30 years. That makes the Rio Tinto and the Calumet & Hecla look small. There is much left for him to do, and in the doing of it we wish him some of the luck that every miner needs. His career testifies to the opportunities that the United States offers to the hard-working, self-reliant, keenly observant young man. His is one of those romances of industry on which we may dwell with pleasure. To other young men of this democracy it is an encouragement to work hard and to work intelligently not only, or chiefly, to make money, but to win the supreme delight of a great achievement.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Socketing a Wire-Rope

The Editor:

Sir—The first objection to John A. Roeblings' Sons Co.'s method of socketing a wire-rope, made by F. H. Mason, of San Diego, in your issue of March 31, is, I believe, without foundation. It is not necessary for the individual wires to become alloyed with the zinc. Some authorities advocate merely separating the strands of the rope after pushing it through the socket, driving wedges or taper-pins between the strands, and cementing with lead or babbit. No alloying of the lead, or babbit, and wire is supposed to occur in this method. To the second objection I will say that the amount of free acid left on the rope before the zinc is poured is necessarily negligible, otherwise the molten zinc would be blown from the socket, the action being the same as that occurring when babbit is poured into a damp bearing.

Probably more ropes break where they leave the socket than at any other point because of the sharp bending action which takes place. On account of this, and because it is hard to see the conditions of the rope just within the socket, the rope should be cut at the socket and re-socketed at regular intervals. The heat of the molten zinc may slightly anneal the wire below the socket but I cannot see how this would lessen the tensile strength of the rope. It is more likely that it presents crystallization and to some extent prevents breaking.

With the method suggested by Mr. Mason, the strain of the load would come on only a few wires as it is impossible to bend them so that they will all be drawn taut together. A few will be tight, others will rest alongside, slack.

Hammering the rope in place is objectionable, as it tends to sharpen the kink formed by bending the wire, perhaps breaking the end off.

Miami, Arizona, April 5.

PHIL LAUZON.

The Editor:

Sir—The method of socketing wire-ropes given by the Roebling Co. is in my opinion the safest. I have tested eight sockets on a $\frac{1}{2}$ -inch (6 strands 19 wires) crucible-steel rope and I have observed tests made by the Hazard Rope Co. at Wilkesbarre, Pennsylvania. In every case the full breaking-strength of the rope was developed and the wires in the zinc cone were in no case disturbed.

In the Roebling description two important steps in the process were omitted, 'tinning' the wires and heating the socket. In order to make the method clear I shall give the whole process.

There are two kinds of sockets, the open and the closed. The open socket lends itself best to the socketing

operation because after the cone is put on it can be pushed out of the socket and inspected. If the wires are spread out and then pushed up into the socket the cone cannot be pushed out of the socket unless the serving at the base of the socket is removed. A better way is to slip the socket onto the rope and serve it at a distance from the end equal to the length of the bowl of the socket.

After this is done, open the wires, straighten them, and cut out the core. Clean off the oil with gasoline. The wires must now be 'tinned,' as the expression is. Dip the opened wires in zinc chloride, and then in molten zinc. Great care should be taken that the core is not saturated with acid and the wires must be dipped in the zinc more deeply than in the acid, in order to burn off the acid. When the wires are removed from the zinc

CROSS-SECTION OF ZINC-CON

they should be knocked against something to shake off the excess zinc. This operation of 'tinning' should be repeated until all of the wires have a coating of zinc. If they are not so coated they will not be held securely. The zinc chloride solution is made of 5 parts hydrochloric acid, 3 parts water, and enough zinc almost to consume the acid.

Now pull the rope back into the socket as far as the serving will allow. Heat the socket with a blow-torch and pour in the zinc. The zinc should be hot enough to flow freely. The socket is heated to prevent too sudden chilling. Allow it to cool for at least 10 minutes. After the cone has cooled, push it out of the socket and inspect it. If it is not a smooth job, cut it off and try it again. The cone should be as long as the socket will allow.

The accompanying photograph is a cross-section of a zinc cone that was in use while breaking a $\frac{1}{2}$ -inch crucible-steel rope. The black spots are the wires.

Berkeley, April 23.

W. S. WEEKS.

Surface-Tension

The Editor:

Sir—I was much interested in the articles appearing in the book, 'The Flotation Process,' edited by T. A. Rickard and re-printed from your paper. I was especially interested in an article by Oliver C. Ralston entitled 'Why do Minerals Float?' on page 175 of the book to which I have referred.

Mr. Ralston, in discussing the theory of flotation, naturally has to deal with the structure of thin films and with the phenomena of surface-tension. I was much surprised, however, at two statements made by Mr. Ralston: one was to the effect that the density of the surface film of water at ordinary temperatures averages 2.14 as compared with unity for bulk-water. His second statement was a natural corollary to this, namely, that heat is liberated when a definite area of new surface film is formed, measured and found to be 0.00315 calories per square centimetre of surface. It is evident, of course, that if the density of the surface film is 2.14 times that of bulk-water, the liquid in the film must be under greater compression than the liquid in the interior and it follows that owing to the compression heat will be liberated when liquid moves from the interior to form a new surface.

Both of these statements are wrong and are easily shown to be so. Mr. Ralston made them on the authority of Dr. W. C. McC. Lewis.* He did not notice that in a later number of the *Philosophical Magazine*,† Dr. Lewis stated that he no longer regarded the views set forth in his previous paper (the one from which Mr. Ralston quotes) as at all tenable. If E represents the total energy of unit-surface, S the surface-tension, and T the absolute temperature, we have the following well-known relationship from thermo-dynamics: $E = S - T \frac{dS}{dT}$. Now the surface-tension of a liquid always decreases with a rise in temperature and therefore $\frac{dS}{dT}$ is negative and $-T \frac{dS}{dT}$ is positive. If therefore we increase the surface by unity, we do work on the surface equal to S if we keep the temperature constant. But at constant temperature the total energy of the surface is increased by E , which is greater than S by the positive quantity $-T \frac{dS}{dT}$. Accordingly, this quantity of heat must flow in from the surroundings in order to maintain the temperature constant. In other words, if heat is not allowed to flow in from the surroundings, the liquid will cool, when new surface is formed.

The above considerations imply a lower average density in the surface film than in the interior. The prob-

lem as to the variation in the density in different parts of a liquid, however, may be approached from the purely kinetic standpoint. In the interior of a liquid the forces due to the attraction of molecules will balance, since any molecule is surrounded on all sides by attracting molecules. Toward the surface, however, there will evidently be a resultant force directed toward the interior. Molecules will therefore be assisted in leaving the surface layer toward the interior and hindered from getting into the surface layer from the interior. Since in the stationary state, just as many molecules enter the surface layer as leave it per second, the density or number of molecules in unit-volume must be less in the surface layer than in the interior. If the densities were the same and still more if the density in the surface layer were greater than in the interior, more molecules would move toward the interior than toward the surface layer and the state would not be stationary.

We conclude therefore that the density of the surface film is less than the bulk of the liquid and that heat is not liberated when additional surface is formed. The surface of a liquid may in some respects behave like an 'elastic skin,' but this ought not to lead one to think that the surface film is denser than the rest of the liquid.

F. H. MACDOUGALL.

University of Minnesota, April 19.

Tin and Tungsten

The Editor:

Sir—I have been reading your valuable article in the March 31 issue regarding the production of tungsten and tin in the Black Hills of South Dakota.

Several years ago while superintendent of the Forest City Mining Co., formerly known as the Clara Belle mine, while running a drift at a depth of about 250 ft. I encountered a body of tin ore 3 ft. thick, about 15 ft. wide, and extending to view something over 100 ft., where it disappeared into the side of the drift.

Our chemist, Mr. Alfred Dany, tested several samples of the ore and it averaged 8% metallic tin. From observation made while in that country, I feel very sure that there are large deposits of tin ore around and in Oreville, Pennington county, South Dakota.

Cleveland, April 4.

C. P. DOLE.

PORTLAND CEMENT testing is the subject of a recent bulletin issued by the Bureau of Standards of the Department of Commerce. It sets forth the result of several years' work of a joint commission representing the United States Government, the American Society of Civil Engineers, and the American Society for Testing Materials. It should be in the hands of all cement users.

POTASH is being produced at the Searles marsh in San Bernardino county, California, by the Pacific Coast Borax Co. in conjunction with the Solvay Process Co. The output is in the form of potassium chloride. The capacity of the plant is 1000 tons of the chloride per month.

THE REPUBLIC MILL.

THE GOLDEN GATE MILL.

D. C. Jackling and the Utah Copper

AN INTERVIEW. By T. A. RICKARD

Mr. Jackling, you are a Western man?

I was born in Missouri, and have lived in the West all my life.

When and where were you born?

My father and mother lived in Bates county, before there were any railroads west of St. Louis. My father was engaged in the trading and forwarding business, on the Santa Fe trail, at the old town of Hudson, near what is now Appleton City. I was born there in 1869.

Your people were of old American stock?

My mother's people were of old American stock, but my father came from England while a young man; he was naturalized in this country not long afterward; and for a time, immediately following the rush of settlers in the early 'fifties, was engaged in a small way in the shipping business of the Pacific Coast. None of his relatives came to this country so far as I know, except one sister, whom I never saw.

From what part of England did your father come?

His family lived in Lincolnshire, but he went to Liverpool while he was a boy.

That accounts for his interest in shipping?

Probably.

Will you outline your early education?

It so happened that my father died before I was a year old, and my mother before I was two years old; and as I knew nothing of the whereabouts of my father's relatives, if there were any at that time in this country, to all practical purposes I had no relatives on my father's side, so I was taken to live with a maiden aunt, my mother's sister.

What was her name?

Her name was Abigail Dunn, a good old Irish name. My father's stock was English and Scotch, his father having been an Englishman. My mother's family were originally Irish.

Please proceed with your education.

My mother's sister married a farmer. We lived on a farm during all my early life, migrating from one point to another, sometimes settling for a year or so in one place. First we went from Missouri to Arkansas; from Arkansas to Illinois; from Illinois back to Missouri, and rambled all over that country during my boyhood until the time that I first went to a little school-house near Monmouth, Illinois. I didn't start to go to school until I was old enough to walk the two miles and return alone. As I had opportunities, I went to the common district-schools during the winter, possibly half the winter, until I was about 16 years old; and then my aunt's family, with whom I lived, moved to Sedalia, Missouri. Prior to that time, I had been living on a farm in the Flint Hill country bordering the Missouri river, where picking was pretty thin.

At Sedalia, I managed to go to the public schools for two terms, and just got into the eighth grade. Part of the time I was working for my uncle as a teamster, hauling wood, on public work, hauling earth from excavations, stones for foundations, brick for buildings, and all that sort of thing, nearly always as a teamster. Then I worked out for a year on a farm at \$14 a month, and commenced to save a little money. I came back and worked again for my uncle at this same sort of general work, driving a team—that was the only thing I had

ever known. After an interval I resumed work on the farm for another summer.

Had you any idea of a career?

I was then 19 years old and had made up my mind that I wanted to go to school; in fact, I got the idea of wanting something more of an education through a nephew of the man for whom I was working on the farm. The nephew was teaching in the district-school, getting \$30 a month and board. He went up to St. Joseph and got a job clerking in a hardware store at \$75 a month. I heard his aunt and uncle talking about how well he was doing, and I reckoned that if I could become a school-teacher I might also get to be a clerk and make \$75 a month myself. I was only getting \$14 a month, but saving some of that; and I figured that if I could earn \$75 as a clerk, I could save at least \$60 each month. Good farm-land was only \$20 an acre, so I calculated I could save enough to buy three acres each month, or 36 acres a year. Eighty or 100 acres of land was a good tract, and I could see my way to agricultural independence; and agriculture was the thing I knew best.

So, what did you do?

I went back home, and got things shaped around so I could go to the State Normal school, at Warrensburg, Missouri, at the beginning of the term in September, 1888. I stayed there that year, and got along pretty well; but concluded that school-teaching wasn't exactly the thing I was looking for; and began giving considerable thought to the question of engineering.

How did that idea arise in your mind?

While teaming, I had become interested in the work of city engineering, such as laying out streets, and that sort of thing; I hadn't seen any real engineering, but the use of the transit and level captivated me; so I got it into my mind that I would like to study civil engineering. I worked again on the farm that summer, and in the autumn of 1889, when I was 20 years old, I started for the Missouri School of Mines, at Rolla, Missouri.

Were you sufficiently prepared to enter?

I was not sufficiently advanced to enter in the freshman year of any technical course, so I had to take some preparatory work, and pursue a mixed course for the first year. I didn't have any money, except what I had earned myself in these years on the farm and otherwise, but I had earned about enough to pay my first year. It didn't cost me much, because I got room and board for \$12.50 a month.

In what other ways did you obtain funds?

During the summer vacations of the first and second years, I got a job on the M. K. & T. railroad, in the maintenance-of-way department, and worked in Texas, Indian Territory, and Kansas. Thus for part of the time I had to do with real construction work, building an extension of that line from Coffeyville, Kansas, into Indian Territory, now Oklahoma. I had my first real engineering experience there, and by the time I had worked my second summer, I began to get some knowl-

edge of engineering things. I went back to school again in the fall; and the next summer, I stayed on during a summer session. In the meantime I had been appointed student-assistant to the Professor of Chemistry and Metallurgy.

What was his name?

Cuthbert P. Conrad. I think he was from Pennsylvania. Early in the following year he died, and I then had charge of the chemical department, and at the same time I was carrying on my own studies.

In which branch of engineering?

I had abandoned the civil engineering course, as my experience on the railroad did not appeal to me. I wanted to take a course in mining engineering and metallurgy, but didn't have time to do it. The metallurgical course was shorter, so I worked to the degree of Bachelor of Science in Metallurgy. According to the rules of the Missouri School of Mines, it requires some practical work before one can get the degree of Metallurgical Engineer.

In what year did you graduate?

Going unprepared in 1889, and in part earning my own way by working during my vacations and being assistant in teaching part of the time, I finished the four years' course in three years, and graduated in 1892. I did not get my engineer's degree until ten years afterward, in 1903.

What did you do then?

I stayed at the Missouri School of Mines as assistant Professor in Chemistry and Metallurgy for another year after I had graduated, and left there finally in 1893.

And you went from there to—?

I changed my mind pretty frequently. First I was going to be a school-teacher; then a civil engineer; then a mining engineer, but found my work was leading me into metallurgical studies, and lastly I was pruning again for a career of teaching. After a year of that, I concluded I didn't like it, pulled up without anything particular in view, and started out to look for a job. I went to my uncle's farm during the summer months, and tried to find a position by correspondence. I was offered a position as teacher in some of the schools, but I had decided I didn't want that; so in the autumn of 1893, I went to Kansas City. The old Kansas City Consolidated Co.'s Argentine plant was running then, and some of my friends were working there.

Whom did you meet there?

Curtis Alexander was the assayer, and I tried to get a position from him, but failed. The only thing I could get was a job pushing slag-pots. That was all right, but just about that time, Cripple Creek was beginning to attract a good deal of attention, and I decided I would go there.

Did you know anybody at Cripple Creek?

I didn't know anybody in the West at all, but I got together what few things I had and prepared to go anyway. I found I hadn't enough money to pay for a

LABORATORY IN THE ROLLA SCHOOL OF MINES. MR. JACKLING IS INDICATED BY THE ARROW

ticket, but I got a little from my aunt; she did not have much, but had always helped me some, so I borrowed enough money from her to get me to Colorado Springs. I landed there a day or two after New Years' day 1894; and went up on the Midland to Divide the next morning. There was no railroad into Cripple Creek then. I could not afford to take the stage, so I got a fellow-passenger to take my grip on the stage, and I traveled along behind on foot to Cripple Creek, walking the 18 miles.

Whom did you meet first in Cripple Creek?

I didn't meet anybody that I knew there. I had never been west of Kansas City, and didn't know a soul in Colorado. Some of the boys at the School of Mines came from Colorado, but their whereabouts were vague to me, so I was without an acquaintance in Cripple Creek.

How much of your money was left?

I had only three dollars when I got to Cripple Creek, and that didn't last very long. One couldn't buy much with three dollars in Cripple Creek at that time. I spent all my money for food and was unable to pay for a room. I went to Victor, but couldn't find anything there either, and finally wound up on top of Bull Hill, where I obtained a job bucking samples in J. C. Staats' assay-office, near the old Pharmacist mine. That was early in January, 1894.

So that was your first work in mining?

Yes. I worked for Staats for a while, and when he wanted to go away for two or three months, I ran his business. I did well; it paid very nicely. In the meantime, the first Cripple Creek strike came on. By that time I had located some people I knew. One of them was F. N. Flynn, who had been an undergraduate stu-

dent with me at the School of Mines. Later on, when Staats came back and took his business, I went to work in a shaft on the old Lottie Gibson, but only worked there a short time.

D. C. JACKLING, F. G. JANNEY, AND G. O. BRADLEY, AT MERCUR IN 1898

And what was your next step?

In the meantime Ed. Holden, Charlie MacNeill, George Pierce (of the Golden Fleece mine), and Captain De Lamar had organized a company for starting the first barrel-chlorination plant in Colorado, and were about to rehabilitate an old stamp-mill some little distance below Victor, known as the Lawrence plant. I had heard of this scheme and had talked to Staats about it. He telephoned to Charlie MacNeill for me. Charlie was secretary of the company. I went down there to get a job, and bumped into Ed. Holden, who was running the business as the chief executive. Dawson Hawkins was superintendent. I saw them start on practically the first reconstruction of that old plant, which proved to be the one in which the chlorination process that took so much gold out of the Cripple Creek ores was developed. Chlorination was ahead of cyanidation. John E. Rothwell was there part of the time. He had been engaged as consulting engineer, and had come down from the Golden Reward, in the Black Hills, where he had been putting in a barrel-chlorination plant.

What appointment did you obtain?

I started to work at the Lawrence plant as assayer, and, as time went on, got more deeply into the technical department, and pretty soon I was doing all the chemical work. Finally the chiefs of the metallurgical department, Rothwell, Hawkins, and all the rest of them, went away, and I was the chemist and metallurgist for the plant.

That must have been in 1894, for I remember examining the Elkton and going down to the Lawrence plant with Dawson Hawkins, who introduced us. Do you remember?

Yes, I do. That was in the fall of 1894. I stayed there until the latter part of 1895, when the plant burned down.

But chlorination had won a foot-hold, had it not?

Out of the Lawrence experience grew the MacNeill and Penrose installations at Colorado City. The Gillette plant, a small chlorination mill, was built in the meantime at Grassy by Ned Hawkins, a brother of Dawson Hawkins. Dawson had left Lawrence, as I have said, and I don't know but what he was associated with his brother Ned for a while in building this Gillette plant.

After the Lawrence plant was destroyed, MacNeill got together another organization, using the data from the Lawrence experience, and organized the Colorado-Philadelphia Reduction Co., which built what was called the Colorado plant. That was the first big chlorination plant in Colorado, and was at Colorado City. Later they built a still larger plant, called the Standard, also at Colorado City.

In the meantime, Argall had built his Metallic Extraction cyanide plant at Florence; and then others followed. The whole metallurgical trend for Cripple Creek ores, outside of Argall's work, was toward chlorination. The National mill was built at Florence, and

was a good-sized plant; the Union, which was a very large plant, was also built there; and about the same time the Portland mill was built. The Lawrence mill was the nucleus from which grew the reduction works that for a great many years treated nearly all of the Cripple Creek output. Argall's plant was closed down when the United States Refining & Reduction Co. was organized, but he lived to see his ideas re-established, although along somewhat different lines.

The burning of the Lawrence plant was the end of my experience in the Cripple Creek district. I then made some examinations for Captain De Lamar, who owned a large interest in this Lawrence plant, but he did not go into the Colorado City enterprise. In the meantime De Lamar had become interested in the Mercur district, Utah, and had organized a company called De Lamar's Mercur Mines.

But this enterprise did not include a chlorination mill?

No. The old Mercur Gold Mining Co. was the first in the country that had employed the cyanide process successfully, and upon a considerable scale. It had used it on the oxidized ores of the upper zones. The mines controlled by Captain De Lamar lay in a lower geological topographical horizon; and a large part—the most important portion—of their orebodies was non-oxidized ore that was not amenable to any known method of treatment in their natural state, on account of base sulphides of various kinds. There was almost everything that one could imagine, but the principal refractory constituents were mispickel, the arsenide of iron, and the two arsenides of sulphur, realgar and orpiment.

Did you discover a way of treating this ore?

Captain De Lamar acquired these interests in 1895, or about that time, and during that year sent considerable quantities of these ores over to me for experiments at the Lawrence plant. I thought there was a way out of the difficulty in treating them; very few others did. He had sent samples to Europe and elsewhere, and the metallurgists had all reported that there was no method applicable to that low-grade refractory ore. I had made some experiments in Colorado, and thought something could be done. At the same time, I had conducted a series of experiments on the ore of the Jim Crow and Monitor mines, which formed the basis of De Lamar's Nevada property, not far from Milford. Early in the year 1896, De Lamar engaged me to go to Mercur and commence more extensive experiments, on my representation to him that I had obtained some results that were promising, and that I believed offered a solution of his problem.

What men were there at that time?

George H. Robinson was manager of the De Lamar Mines then; and R. H. Terhune, of the old Hanauer smelter at Salt Lake City, had been engaged as metallurgist to advise him about some method of treatment; but nothing had been done at all. I took hold of the research and worked with Terhune. After a little while, he dropped out, and I was authorized to build an experi-

THE GOLDEN GATE MILL AT MERCUR, IN 1898

mental plant. In two or three months, in May or June, 1896, we had the little plant ready, and commenced operating on a small scale, a few tons a week, getting good results. I carried the experiments through until late in that year, and got definite and satisfactory results, which I believe were among the first, if not the first, based upon the roasting of ores for cyanide treatment anywhere in the world. Argall may have done it at Florence before; but the work at Mercur was the basis of the first big installation of a cyanide plant that contemplated the roasting of ores before cyanidation.

What were your difficulties?

We had a problem more serious than the elimination of the sulphur; and that was the lime and clay base of the ore which formed naturally a good cement-making product; so that after we roasted the ore and put it into vats to leach, we found it setting into masses of solid concrete. We had that to overcome, but we did overcome it by carefully wetting, mixing, and seasoning the ore before charging it into leaching-tanks. At the end of that year, we commenced designing a 500-ton plant.

What other innovations do you recall?

That experimental plant was, so far as I know, the first place in the country where powdered zinc was used as a precipitant for cyanide solutions on a commercial scale. C. W. Merrill came there with Henry Bratnobar and others in the autumn of 1896 to examine the mines, and I believe Merrill saw there the use of zinc-dust for precipitation on a commercial scale for the first time. I used it in the old way—adding it direct to the solution-tanks and agitating with air. In the meantime, between the operation of this experimental plant and the construction of the first section of the De Lamar Mercur Mines mill, the De Lamar Nevada Mines had changed

their process from chlorination to cyanide, and there used on a large scale zinc-dust precipitation before we used it on a similar scale at Mercur; but the application of it on a working scale was elaborated in the little experimental plant at Mercur.

Early in our use of zinc-dust, we found that certain kinds didn't give as satisfactory results as other kinds, and by analysis I determined that the amount of impurities had a marked effect, and found that the purer dust didn't work so well as that which was less pure and contained some considerable percentages of lead; so I corrected the defect in the purer dust, so far as I know for the first time, by adding a solution of lead acetate to the precipitation-vats. I believe that sodium cyanide was used in this mill at Mercur for the first time, on a large scale.

In what year was that?

We started to build a 500-ton plant at Mercur in the summer of 1897, commencing on the foundations in June of that year; and in April, 1898, we ran the first ore through it, having built the first all-steel mill in the West; and having employed in a large way, for the first time, electric current transmitted at 40,000 volts for milling purposes, using the induction-motor. L. L. Nunn built the Telluride power-plant at Provo, and had introduced these improvements in a small way in Colorado, but we took this power at 40,000 volts and had the first large installation served by high-potential transmission in America, I think—in the Golden Gate mill at Mercur. Anyhow, so far as I know, we used for metallurgical purposes of that kind, and on a considerable scale, the first induction-motors to be so used. We had a good deal of trouble in starting up that plant; we had introduced so many new devices. There was some trouble

with the power; and we found that the roasting-furnaces were not particularly well adapted, and had to design our own furnaces.

What furnaces were you using?

Horace F. Brown, the straight-line roaster. We had a double problem, one of roasting and one of cooling. The Brown did the roasting, but we had to combine cooling and spraying to get the product in proper condition to put in the vats. One of the methods for overcoming the 'setting' of the cement-like material produced by roasting was to spray the ore with water while it underwent stirring and cooling, and thus allow it to agglomerate and set in small granules, which were sufficiently porous for good leaching. We further overcame the 'setting' by mixing with the roasted ores a certain percentage of oxidized ores that did not need roasting and only required comparatively coarse crushing, so we finally got a product that would leach satisfactorily and could be removed from the vats without difficulty.

What furnaces did you use then?

We remodeled the Brown furnaces and got them to working fairly well, employing for the first time, so far as I know, the top of the furnace for a cooling-hearth. We sprayed water on that, and got a satisfactory product. We then designed a furnace of our own that was called the Jackling furnace. It was designed not because I had any ambition to invent a new apparatus to bear my name, but to meet a necessity. In the meantime we had put in some Holthoff-Wethey furnaces. We started with four furnaces only of the Brown type, later adding two of the Holthoff-Wethey type, and then three of the so-called Jackling type.

Who was manager of the Golden Gate mine at that time?

In the meantime, George H. Robinson had resigned, and H. A. Cohen became general manager, and he in turn was succeeded by Victor Clement. Duncan MacVichie was superintendent of the underground operations and I was superintendent of the surface operations.

We employed there, I think for the first time, a large-capacity induction-motor electric hoist. This hoist was controlled by friction-clutches and reversing-gears between the motor and the drum.

Won't you say something about the first use of sodium cyanide?

I found we had so many acid salts, which we were pleased to call 'cyanicides' at that time, that the consumption of cyanide was very high. Potassium cyanide pretty nearly all came from across the water, and was expensive. In order to overcome these cyanicides, we bought soda-ash as a neutralizer, and used that in making up stock solutions before adding cyanide. The first observation that suggested the use of sodium cyanide was due to our having received a lot of potassium cyanide that was very impure, and the question was raised as to whether or not that was as valuable as the purer potassium cyanide. I reasoned that if I had a solution of alkaline cyanides with a very large quantity of caustic soda present, I didn't know whether I had potassium or

sodium cyanide and, as a matter of fact, sodium having a lower equivalent, that if we used more of the sodium cyanide, we would have more of the active agent cyanogen present per unit of chemical. Thus it developed that sodium cyanide was just as good for us, and we gradually changed from the use of potassium cyanide, which was expensive, to sodium cyanide, which was much cheaper.

So you began to do good work?

We got that plant into very successful operation, and up to its full tonnage about the end of the year 1898, and began enlarging it; and those enlargements were in part completed, and in part under way, when I resigned in December 1899.

Who succeeded you?

When I left Mercur, I turned the operation of the plant over to F. G. Janney, who became superintendent of the mill. Janney theretofore had been my assistant, practically since the beginning of the construction of the plant in 1897. That was my first association with Janney.

You went to Salt Lake?

No. Clement had resigned; and I went at his suggestion as consulting engineer to design a mill and process for some mines at Republic, Washington. Clement had known something about these mines, and thought they had pretty good prospects.

Was Clement connected with these mines at Republic?

No, but his friends Volney Williamson and Patsy Clark, of Spokane, were. However, before I went there, they had sold out the larger part, if not all, of their interests in the Republic mines to some Canadian people, Clarence McCuaig and other capitalists. I was employed by McCuaig and A. A. Ayer, of Montreal, to go to Republic and design a bigger plant than the one they had there, and a more economical one, which I did. Up to that time, they had been using a small mill, employing the Peletan-Clerici process. I sent my metallurgist, Herbert Fox, to Republic in the latter part of 1899, and he worked out most of the metallurgical data, so that when I went there in 1900, we were pretty well prepared to go ahead. We built a 250-ton mill that year, and started it in the winter, running it the better part of the next year. It did economical work and made good recoveries, but the ore developments and reserves were not up to expectations, so the mill had to close-down late in 1901.

What did you do then?

I went back to Colorado again as consulting engineer for the United States Reduction & Refining Co. under engagement by my old friend MacNeill.

You mean consulting metallurgist?

No, the title was consulting engineer. I was getting out of the technical metallurgy and more into engineering and construction lines.

As I have said, I went back to Colorado, and about that time, the U. S. Reduction & Refining Co. had its

THE UTAH COPPER HILL IN 1904

attention drawn to the utilization of low-grade lead and zinc ores, more particularly from the Leadville district, as employed in making zinc-lead pigment at Canon City; and they sent me there to look into F. L. Bartlett's plant. The result of that examination was that the U. S. Reduction & Refining Co. purchased the Canon City pigment plant, and sent me to re-build and operate it. I stayed there during 1902 and 1903, and we developed the business to a profitable condition. It would have continued to be profitable for a long time but for the fact that

metallurgy was developing more rapidly in other lines.

To what do you refer?

The electro-magnetic separation of zinc and lead ores had commenced to interest people in the West; instead of the Canon City plant being able to get such ores practically on a lead-smelter basis, whereby they paid for the lead while the zinc was penalized, it found itself having to compete with people not only willing to take mixed ores without penalizing them, but beginning

THE UTAH COPPER HILL IN 1914

to pay something for the zinc, using the Wetherill process. The Empire Zinc Co. in the meantime had built an experimental plant at Canon City and was buying ores; and other plants grew up in Colorado of a similar kind, or at least designed to do the same thing, so that eventually they put the Canon City pigment plant out of business—but not until some time after I had left it.

Where did you go?

In the autumn of 1903, I was called back by De Lamar to Salt Lake to attend a suit over the interpretation of an electric-power contract we had made with the Teluride Power Transmission Co. while I was superintendent of the plant at Mercur. This suit kept me in Salt Lake City for about two months, or until the beginning of 1904.

Here I must break the story, and go back to 1898 and 1899, when I was still at Mercur. Captain De Lamar had his attention called at that time to the Wall group of claims, which constitutes a part of the present holdings of the Utah Copper Co., in Bingham Canyon, and which formed the initial basis of that company's organization. These claims had attracted the attention of Captain De Lamar's engineers while working under the management of both Cohen and Clement. About that time, and following the success of the cyanide process at Mercur, a good deal of attention was being given to some low-grade gold-ore deposits, mostly in the form of gossans, or outcrops, in the Bingham district.

The old Stewart mine, which was the nucleus of what was later the Boston Consolidated group, had been first worked for gold. In the meantime Thomas Weir had built a cyanide plant to treat some surface gold ores on the Highland Boy group, which later became known as the Utah Consolidated. Others had begun experimental operations, at least, on similar ores on some of the claims that now form a part of the United States Mining Co.'s holdings, the old Telegraph and Niagara.

The Wall group was first sampled by De Lamar's representatives with a view to determining whether or not the ore also contained enough gold to make it profitable.

By cyanidation?

Yes. The samples that were taken in 1898 were sent to Mercur for assay, and it was found that there was no considerable quantity of ore containing commercial values in gold; but it was recognized at the same time that a very large quantity of ore did exist containing about 2% copper, and in some places better than that.

Recognized by whom?

It was self-evident.

But ore of that low tenor was hardly interesting at that time?

That will develop. I was sent to Bingham about the end of 1898 to take charge of some development work and make a report on the possibility of handling these low-grade copper ores at a profit. I believe the first churn-drilling for the purpose of testing copper ore-

bodies was done at Bingham at that time, when two churn-drill holes were driven to a depth of several hundred feet. We started, in addition to the drilling, to do some tunneling, and drove several hundred feet at various places into the hillsides.

We re-modeled an old five-stamp mill that was on the ground and had been used in the early days as a gold mill, and crushed several hundred tons of the ore as we took it from the tunnels, concentrating it on Wilfley tables and vanners. We shipped the concentrate to the old Germania smelter near Salt Lake, and I made a report to Captain De Lamar in the summer of 1899 in which I expressed the belief, based upon my investigations, that there was not only a very large quantity of ore that would average 2% copper, but that it could be worked profitably on a large scale.

R. C. Gemmell had for a long time been associated with the Mercur operations as the chief mining engineer, and he assisted me in making that part of the report pertaining to the development of the orebodies and the probable amount of tonnage. We calculated at that time there was definitely demonstrated not less than 9,000,000 tons of ore that would run something better than 2%; and we expressed it as our view that additional development work would result in proving not less than 25,000,000 tons of similar ore.

The report I made to Captain De Lamar contemplated the same general plan of operation that is now employed. I recommended building a plant at what was known as Adamson Springs, not far from the shores of Great Salt lake, and on precisely the same site that the Magna plant of the Utah Copper Co. now occupies. This recommendation was made because there was neither water-supply nor available room for the storage of tailing in the vicinity of Bingham, and the site selected provided ample facilities in both respects.

Captain De Lamar, for various reasons, principally, I believe, the large amount of money that was involved in putting the proposition on a profitable basis, did not look with favor upon it.

What was the price of the mine?

Captain De Lamar had paid \$50,000 for a one-fourth interest when he started to develop; he had an option to buy other interests, the terms of which I do not recall now. He had agreed to spend an additional amount in development. The total expenditures in purchase and development made by Captain De Lamar amounted to something less than \$100,000. He dropped the proposition, but had acquired a one-fourth interest in the property.

How much money did you estimate would be required to put the enterprise on a profitable footing?

Several million dollars to build a railroad and put the thing on a profitable basis. I recommended an initial operation of 2500 tons per day; that seemed a tremendous figure at that time. Of course, I had in mind an increase of tonnage later, but 2500 tons per day was to be the scope of our operations at the start.

You don't remember the amount of money you estimated to be necessary?

It wasn't very definite, but, roughly speaking, it would have required around \$3,000,000.

The matter was dropped, and I then went to Republic, Washington; but I kept the idea in mind, and called the possibilities of the proposition to the attention of several men who were interested in the copper industry. During the next three years, I lost no opportunity of interesting people who had the money and were familiar with the industry in a proposition that I thought offered the biggest opportunity I had ever seen.

You did not succeed at first?

When I went back to Salt Lake in the winter of 1903, I endeavored to secure an option from Colonel Wall on

ceeded in getting an option on 80% of his 75% interest, or 55% of the property.

I took the option to Colorado, and presented it to MacNeill, who, after some hesitation, interested himself to the extent of sending an engineer, selected by R. A. F. Penrose, to go over the property, and sample it, as Gemmell had done in 1898 and 1899.

Who was the engineer?

F. H. Minard. This sampling verified all of my representations and Gemmell's as recorded in our joint report, both as to grade of ore and prospective tonnage; but Mr. Minard expressed the view that more preliminary metallurgical experimentation should be conducted before the proposition would warrant the expenditure of sufficient money to develop and equip it to

THE UTAH COPPER GROUND AND D. C. JACKLING'S EXPERIMENTAL MILL IN 1898

the property, believing that I could interest my associates in the United States Reduction & Refining Co., Messrs. MacNeill, Penrose, and Tutt. Colonel Wall declined to give me an option, saying he had a tentative option out on the property at that time, but that he had little hope of anything being done, and believed the time was not right to dispose of the property to good advantage. He expressed the belief that it would ultimately be valuable, but thought the value was a prospective, rather than a present, one. H. A. Cohen, De Lamar's former manager, was present in Salt Lake City in connection with the power litigation; and I again discussed the matter with him, and told him that if he could secure an option, I believed I could interest my associates in Colorado to an extent that would induce them to provide the money necessary to demonstrate the proposition, at least on a moderate scale. Cohen went to Colonel Wall and suc-

ceeded in getting an option on 80% of his 75% interest, or 55% of the property. I took the option to Colorado, and presented it to MacNeill, who, after some hesitation, interested himself to the extent of sending an engineer, selected by R. A. F. Penrose, to go over the property, and sample it, as Gemmell had done in 1898 and 1899.

So your friends were willing to go ahead?

Yes. Mr. MacNeill and his associates decided that the proposition warranted the necessary expenditure to determine whether or not the operation could be made profitable in a comparatively small way, and correspondingly more profitable in a larger way; so a small exploitation company was organized to build a mill in Bingham Canyon. We styled it an experimental plant.

This mill was designed for a capacity of 300 tons per day. Construction began in August 1903, and we ran the first ore through the plant in April 1904. The first step toward opening the mine for actual production was taken in November 1903, in starting what was known as the old 'main tunnel.' The plant started up, as stated, in April 1904, but did not develop its full capacity of 300 tons per day for nearly a year.

You might say something about the recoveries, if you can.

From the start, the recoveries verified the preliminary results that had been obtained a few years before, and the plant actually made a profit every month from the day it started.

You don't remember any of the percentages?

We were running on an ore averaging about 2%, and were recovering a little less than 70% of the total copper in a concentrate averaging around 25%. The plant having demonstrated that the mine could be profitably operated, we began making plans for a larger installation at Garfield.

In the meantime, Captain De Lamar's one-fourth interest had been purchased, thereby giving the Utah Copper Co. (of Colorado) an 80% interest in the property; and a new company was formed which took over the original Utah Copper Co.'s 80% and Colonel Wall's 20%, in consideration of stock interests in the new company, which was then called the Utah Copper Co.—the same name, only the original corporation was registered in Colorado, and the new company in New Jersey.

The Copperton plant, as the Bingham Canyon plant was called, was gradually increased until it eventually reached a capacity of 1000 tons per day before it was finally closed-down, after the Magna plant at Garfield had been in operation for some time.

The designs for the Garfield plant, which was to have a capacity of 3000 tons per day, were completed in 1905, and we commenced work on the foundations in the autumn of that year. Legal and other complications, however, made it necessary to discontinue construction work for some time. Wall had brought an injunction suit. The money for the construction of the Garfield plant was provided through the sale of \$3,000,000 of convertible bonds, most of these being taken by the Messrs. Guggenheim.

Was that the firm of M. Guggenheim's Sons?

No, the Guggenheim Exploration Co. Early in 1906, work was again actively started. In the meantime, it had been decided to build the Magna plant for a capacity of 6000 tons per day, instead of 3000 tons, that is, a plant of twelve sections instead of six sections; and it is interesting to remember that the 12-section plant then started provided the same identical buildings that are now accommodating, and in which for long periods last year we averaged, better than 20,000 tons per day. At that time I reckoned that a 'section,' as we designated it, of the mill would have a capacity of 500 tons per day. With the same grinding machinery that

we then installed, we now grind regularly more than 1500 tons per day in excess of the 12 sections.

Was this due to 'speeding up' the machinery?

Yes, and better methods of operation—more method than speed, in improving the operation of rolls and Chilean mills. We are not grinding as fine now as we did then.

You are not grinding as fine now?

No, we cannot grind as fine on the large tonnage we are now handling, but we are preparing to grind finer by aid of heavier and additional machinery, taking advantage of the tremendous improvements in methods of milling that we and others have developed.

The first section of the Magna plant started in the spring of 1907.

That was the year of the panic?

The bad times came in November, when we were just beginning to get well started; but nevertheless we were able to increase tonnage continuously. I can't say when we got up to the originally contemplated 6000 tons, but we didn't do it for over a year.

Getting back to the mine—at the same time we started to build the Garfield plant, we began to figure out the ultimate plan of mining, which contemplated the use of steam-shovels; and the first steam-shovel was put on the property in 1906, after Mr. Gemmell, who was then general superintendent, had gone with me over the most important steam-shovel operations in the United States, more particularly in the iron regions. W. C. Agnew, the general manager of the Mahoning iron mine, came out and made a report. He advised us not to attempt steam-shoveling exclusively, as the country was too rough and we never could get elbow-room; he recommended underground mining or 'glory-holing.' I believe he was then recognized as one of the best steam-shovel experts in this country. He said it was not a good steam-shovel proposition, but nevertheless gave us some most valuable advice. We were working all the time in the face of adverse opinions of nearly everybody; nobody thought much of the schemes that we knew we had to employ to make the operation a success.

The development of the mines and their metallurgy from this time forward are well known history.

In 1910, the Utah Copper Company acquired the property of its neighbor, the Boston Consolidated Co., which in the meantime had also constructed a 3000-ton plant at Garfield.

Which is that, the Arthur plant?

Yes, the Arthur plant, which now, under the same roof, has a maximum capacity of more than 15,000 tons per day. The Magna and Arthur plants combined, during the last quarter of last year, treated at times as high as 40,000 tons per day, and averaged during several months last year more than a million tons per month. You know as much about the rest of the history of the Utah Copper Co. as I do.

I know that it led you to go farther afield.

Yes, while we were developing the Utah Copper, we began to investigate other deposits of a similar kind. The first of these was what is now known as the Nevada Consolidated, of which property the Utah Copper Co. acquired control in 1910, simultaneously with its purchase of the Boston Consolidated property. A large part of the data upon which the Nevada Consolidated enterprise was founded was derived from results of operations in Utah; and when the Messrs. Guggenheim acquired control of the Nevada property, before it was thoroughly developed and before construction began on the plants at McGill, I was consulted regarding the location of the plants and the design of them.

The next property to attract the attention of my friends and myself was the group of mines at Ray, Arizona, now known as the Ray Consolidated. Options were taken on that in 1906, and some exploration by shaft was started. The panic of 1907 delayed developments, which, however, were taken up again late in that year; and the property was finally developed and equipped under my direction.

The Ray was worked unsuccessfully by Alexander Hill, was it not?

Alexander Hill reported on it, but, I believe, it wasn't worked under his direction. Ray had been worked in the 'eighties in a very small way, on some stringers, under much the same conception as some of the property of the Utah Copper had attracted attention in the early days, which resulted in the driving of several tunnels on rich streaks. Later, in 1896 or 1897, an English company built a mill at Kelvin and started to operate; but there was no railroad at hand, and they had based their operations on 4 or 5% ore, which they didn't have in anything but limited quantities.

And then they did not know how to treat the chalcocite?

If they had had 5% ore they would have gotten along all right, but the 2%, of which they had considerable quantities, didn't make both ends meet, and that resulted in failure, so the property lay idle. That was in the late '90s. Between that time and 1906, the Arizona Eastern railway had been built into Kelvin, and a few miles beyond. While Ray was under development, the old Santa Rita mines were brought to the attention of Messrs. Hayden, Stone & Co. by Thomas W. Lawson, A. C. Burrage, and H. H. Rogers, just before Mr. Rogers died. These properties were acquired, and the Chino Copper Co. was formed, that likewise being developed and equipped under my personal direction.

In 1912, the Butte & Superior property also attracted the attention of Messrs. Hayden, Stone & Co. I visited the mines in July 1912 and found that while only relatively small orebodies had been developed, the promise of a much larger one was great. I outlined a plan of development to be pursued for the remainder of that year, and this having fulfilled my expectations, I advised Messrs. Hayden, Stone & Co., in January 1913 to finance the properties for larger operations.

And you, yourself, became interested in them?

Yes, I was interested in all these enterprises, and have always retained as large interests in them as my means would permit.

And you acted as consulting engineer?

I was vice-president and general manager of all of the companies until I relinquished the general manager's title to the local managers, and took to myself that of managing director.

When you went to Butte at that time, you probably had your first glimpse of flotation?

Yes, it was the first I knew about it in practical operation; and the flotation process in its commercial application in a large way in this country was developed by the Butte & Superior Co., under the direction of my engineers.

Which engineers?

Frank Janney, and Frank Janney, Jr., and other engineers that came out of my organization, principally from the Utah Copper Company.

So the Utah Copper in the end was an important factor in flotation?

The general staff operating all these properties was the developing medium for the flotation process.

Will you speak of your Alaskan venture?

In 1911, A. F. Holden and his associates brought to the attention of Hayden, Stone & Co. the Alaska Gastineau mines at Juneau. In 1912, in company with Holden, I visited these properties, and stated my belief that the large deposits of low-grade gold ore there justified development and equipment, which was done; the metallurgical problems and plant-design being worked out by the same engineering staff that had to do with the equipment and metallurgy of all of the 'porphyry' properties and the Butte & Superior; and the mine development and equipment being worked out by the men whom we found in charge of the Alaska Gastineau mines when we became interested.

Who would those be?

B. L. Thane and Whipple, his assistant. Thane was the man who was responsible for the mining operations. *You have had some trouble owing to admixture of waste-rock?*

As a matter of fact, the actual trouble we have experienced was that in parts of the mine, which according to all development records should have yielded a certain grade of ore, it was found when we came to mine it, that the grade wasn't there, and isn't now.

To what extent, Mr. Jackling, do you believe that large bodies of such low-grade ore can be sampled?

Large bodies of the kind of ore that we have in the 'porphyry' deposits, and located as these deposits are, can be thoroughly sampled at reasonable expense, because we can drill them; but large bodies of very low-grade ore, and particularly gold ore, such as those of the Juneau properties, cannot be satisfactorily sampled. We have learned that they cannot be tested within the

PANORAMIC VIEW OF THE TERRACED EXCAVATIONS MADE BY STEAM-SHOVELS ON THE PROPERTY OF THE UTAH COPPER COMPANY AS SEEN
MATERIAL REMOVED, 66,000,000 CUBIC YARDS, CONSISTING OF

limits of reasonable expense for development, and with any satisfactory degree of accuracy compared with ordinary deposits.

You agree, then, that we cannot find out how many raisins there are in the cake, except by eating a large portion of the cake?

That is the answer as to a deposit like that exploited by the Alaska Gold Mines. You must mine a large tonnage and mill it and get your result in order to know what the grade of your ore is. The proportion of gold is so small that a few cents per ton—what would be a negligible amount in ordinary ore—makes a vital difference in such low-grade ore; and our experience in Alaska indicates that sampling from development almost invariably shows results higher than they should be. The difference isn't much, only 30 or 40 cents per ton, but that much where the profits were expected to be only 50 or 75 cents per ton is a serious matter.

It is a fact that we know now a thing we didn't know; we had no means of knowing, and no reason to expect before operating the mines, that the grade of ore is quite a few cents a ton less than we thought it was—enough less to make a very important difference. We had a record of milling several hundred thousand tons of ore from a large section of those mines, and this showed the grade of that section to compare closely with our development-grades around it; but it didn't work out that way, and it is apparent now that the section from which the early mining was done, notwithstanding it was not selected—it couldn't have been selected—was a better-grade area than other areas in the development of which the grade appeared to be just as good.

You applied the copper methods of concentration?

Yes, we abandoned in Alaska, as we did in the Boston Consolidated mill, the appliances we thought were obsolete, namely, stamps. We employed rolls and tube-mills in Alaska for fine-grinding and concentration, rather than amalgamation. Our costs are less and our recoveries better than we estimated. There was no error in anything we could demonstrate; we did it on a large scale and the results have proved that we were right. We didn't know so well what was underground; but the best data we could get appeared entirely satisfactory until we began to mine a large tonnage.

Owing to the enormous tonnage of low-grade copper ore at the mines under your control, you are, of course, vitally interested in the flotation litigation?

Naturally so, because flotation has proved the most effective means that we have been able to find to make greater recoveries within the limits of reasonable cost from the finest class of material, which has always been the most troublesome material in concentrating-mills. I don't think flotation is a panacea for all ores; and in the development of a new 'porphyry,' or any other kind of mine having ores which contain sulphides, I wouldn't abandon the old metallurgical methods by any manner of means. I would continue the use of what I have been pleased to call step-grinding and fractional concentration, getting out as much of the mineral in coarse sizes as possible before grinding finer, getting it cheaper than by flotation, because those are simple operations, mostly mechanical, and can be readily observed, making products better adapted to smelting and easier to handle; then use the flotation process as an adjunct or auxiliary to do better with the very fine products than we can do by any other means at permissible costs.

IN 1917. TOTAL VERTICAL HEIGHT FROM BOTTOM LEVEL TO TOP LEVEL, 1420 FT., DIVIDED INTO 23 BENCHES. TOTAL QUANTITY OF 39,700,000 CU. YD. OF OVERBURDEN AND 54,678,700 TONS OF ORE.

Do you care to say anything about your policy in regard to the litigation?

No, under the circumstances, I deem it best not to say anything.

What do you consider the most satisfactory episode in your career?

Of course, from both a professional and business standpoint, I have, and always will have, the greatest satisfaction as being the first, so far as I know, to recognize the possibilities of a character of low-grade ore in the Utah Copper Company's properties that had not before been commercialized, and which kind of ore today serves as the basis of more copper production than the total output of the United States at the time I began the development and equipment of the Utah. The United States was refining 900,000,000 pounds of copper per annum when the Utah Copper Company started, and the porphyry coppers, including those of South America, are producing more than that today. I naturally feel the greatest satisfaction in that; but it is only a greater satisfaction in point of precedence and degree; precedence because Utah was the first, and degree because it is the greatest. I have had just as keen a sense of satisfaction in successfully developing the other mines; the success of any one of them has been no more gratifying than that of any other, and my interest in each has been as great as it has been in any other.

A thing that has been about as gratifying to me as anything I have done is having been instrumental in getting together the Utah Power & Light Co. Water-power had not been developed when we started the Utah Copper operations—not to an extent justifying my using it. It wasn't sufficiently dependable, so we built steam-

power plants. Later, I thought it should be developed, and called the attention of some of my friends and people in that business to the possibilities of power-development in Utah and Idaho. We purchased the Telluride company's properties, and along with that acquired some 30 other corporations engaged either in the production or distribution of power, and out of all we have built up the present Utah Power & Light Co., of which I am president. This company now supplies the Utah Copper Company with all its power and is one of the greatest institutions of its kind in the country.

Do you think it likely that any further large disseminated copper deposits will be found in the West?

I think in all probability there will be some, but I think the most important ones have been discovered and developed; the reason I think that is because all of those that have come into prominence and are big producers today have been known for generations; engineers and laymen have known they contained copper; there hasn't been a single one actually discovered in recent years. The Utah deposit has been known for fifty years; the soldiers of Johnson's army knew about it and prospected in it. The old Ruth mine, of Nevada, and some of the other deposits there, were worked a very long time ago. Ray has been known for over forty years, since 1874, when I believe the first records show somebody going in there and prospecting streaks of high-grade ore. Chino was worked practically by the ancients; there are records of Mexicans having taken copper out and packed it on the backs of 'jacks' to Mexico City in 1804. In the Miami district, the old Black Warrior and other claims were worked for their oxidized copper ore for a very long time; and the green outcrops of the district were

among the earliest known of copper showings in Arizona. The Braden mine was worked by the ancients. The Chuquicamata mine has a record of operations covering hundreds of years. All of the big things of this kind have been well known for their superficial showings of copper ore. People didn't recognize the importance of 'secondary' enrichment; that ore having a low value on the surface was a probable index of higher-grade ores lower down; they looked for veins. Furthermore, modern appliances and metallurgy, as well as cheap transportation and ready markets for large production were necessary to the success of this kind of enterprise.

What is the outlook for copper after the War?

I think there will come a time after the War—I don't predict how soon—when copper will again be very abundant for the world's needs, and that the price will again reach levels that we speak of as being below normal, having in mind the average price of copper for a decade before the War. I think, however, that the situation will quickly right itself; the price of copper must necessarily tend upward. The average price of the metal for the ten-year period preceding the time when we started opening the Utah mines was about 13½ cents; the average price for a period of ten years following that time was about 15½ cents. We have been running those mines now about 13 years; that would exclude the high prices of 1915 and 1916. I believe that another ten years will show an average price nearer 20 cents than 15 beginning with 1915. The price must necessarily go up, because if we consider all the reported developments of copper ore in the world that can be measured, all of the great 'porphyry' reserves, and only consume copper at the present rate, that is, the present normal rate—the rate prevailing immediately before the War—we haven't enough copper ore in sight in the world to maintain that production and supply that consumption for more than a short generation.

THAT MINE-TIMBERS of white spruce, Sitka spruce, white birch, and western hemlock grown in the Chugach National Forest, Alaska, are fully as good as Douglas fir from the Rocky Mountain region and superior to other Rocky Mountain species for use as mine timbers, has been demonstrated by the Forest Products Laboratory at Madison, Wisconsin. Tests to determine the suitability of the Alaskan trees for mine-timbers showed that in bending-strength developed, the four species named are from 20 to more than 100% stronger than lodgepole pine, alpine fir, Engelmann spruce, bristlecone pine, and Western yellow pine from the Rocky Mountain region. These species are all widely used as mine timbers. Sitka spruce, white birch, and Western hemlock from Alaska proved considerably higher in average strength than Rocky Mountain Douglas fir. White spruce averaged nearly as well.

POTASH to the amount of 350,000 tons yearly is wasted in American cement and iron-furnace plants.

Colorimetric Methods for Copper Present in Small Quantities

By R. FRANKLIN HEATH

Recently I was called upon to make a complete analysis of electrolytic lead. As copper was present, I proceeded to determine it by the usual methods, first with KCN and then with KI, but found that the results would not check. I then resorted to the colorimetric methods, and have since been using them for the determination of copper when present in small quantities, as for instance, in non-cupric alloys and bullion, where the copper-content is below 0.05%, although by dilution accurate work can be secured on material containing as much as 1%. A colorimeter or a rack of colorimetric tubes is all that is necessary outside of the regular assay-laboratory equipment. It is necessary to adopt a standard reading-temperature, as color-reactions are somewhat modified by an increase or a decrease of temperature. The solutions must be clear, and the tubes bright and shining, before adding the reagents. It is desirable to maintain an evenly diffused light in which to observe and compare the colors. All the reagents should be of the highest quality. Weigh out 0.1 gm. of copper foil; dissolve in 5 cc. nitric acid; add a few drops of sulphuric acid, and evaporate to expel the nitrous fume; dilute to 1 litre with distilled water; 1 cc. of this solution contains 0.0001 gm. of copper. This constitutes the standard copper solution. To prepare the ammonium-nitrate solution dissolve 10 gm. of ammonium nitrate in 100 cc. of distilled water. This solution is added to the ferrocyanide solution to secure a sharper reaction, whereby the colors are more easily compared. The potassium-ferrocyanide solution is made by dissolving 20 gm. of the salt in 50 cc. of water and diluting to 500 cc.

Take 1 to 10 gm. of the sample, depending upon the quantity of copper probably present; treat with nitric acid; boil until decomposed; add 5 cc. sulphuric acid; boil; filter off the insoluble matter; wash with 25 cc. warm water; precipitate the copper from the filtrate with aluminum foil; collect the precipitated copper; dissolve in dilute nitric acid; boil to expel nitrous fume, and evaporate to 10 cc. in case copper is present only in small quantities, but if present in larger amounts dilute to exactly 100 cc. Have at least two Nessler or colorimetric cylinders at hand, (test tubes may be used); into one of these pour 5 cc. of the ferrocyanide solution; add 10 cc. of the solution of the sample to be determined; dilute to 100 cc. with water; and add 5 cc. ammonium-nitrate solution. In the other cylinder put 5 cc. of the potassium-ferrocyanide solution; dilute to 80 cc. with water; add 5 cc. of the ammonium-nitrate solution, and run in standard copper solution from a burette until the colors match. Note the number of cubic centimetres of standard solution required, from which the copper percentage may be calculated. By using a standard solution of KCN and ammonium hydroxide, copper may be determined in the same manner as above.

Industrial Mining Schools in Nevada

By FRANCIS CHURCH LINCOLN

There are four systems of educating miners in operation in the United States today: (1) admission of miners as special students to certain regular classes in mining colleges, (2) special short courses for miners at mining colleges, (3) correspondence courses in mining offered by mining colleges and by private corporations, and (4) courses given so as not to interfere with the regular work of the pupils at industrial mining schools. Systems of preliminary vocational training, such as mining courses

wasted is profitably employed in study; a supply of trained men for positions of minor responsibility is ensured; and ambitious students are prepared to enter a mining college.

The Mackay School of Mines at the University of Nevada, in Reno, admits miners over twenty years of age to all regular classes which may be of benefit to them; a prospectors' short course of four weeks' duration is given at the Mackay School of Mines each spring, and

NIGHT CLASS AT WORK IN TONOPAH INDUSTRIAL MINING SCHOOL.

in high schools and in mining trade-schools, have been omitted from this classification since their object is to train men to become miners rather than to train men already engaged in the occupation of mining. The special-student and short-course systems do not fully meet the requirements, since a miner rarely possesses the initiative, the spare time, and the necessary cash to take advantage of them. Correspondence lessons sometimes produce good results, but are not as effective as courses directly taught. Industrial mining-schools under good teachers appear to be the most satisfactory means of instructing workmen. The advantages are manifold; the instruction adds to the interest of the men in their work and increases their ability; it improves the safety conditions in the mines and adds to the moral tone of the mining communities. Time that might otherwise be

many miners throughout the State are taking private correspondence school courses in mining subjects. Similar conditions exist in most of the metal-mining States, but Nevada is unique in maintaining four industrial mining schools in the mining centres of Virginia City, Tonopah, Goldfield, and Ely.

Industrial schools for coal miners were first developed in Europe, and were introduced into this country many years ago. The first of these was the Freeland Mining and Mechanical Institute, established in 1879 at Drifton, Pennsylvania, by an eminent mining engineer, Eckley B. Coxe. This school has been in successful operation ever since, and was the forerunner of numerous similar schools in other coal-mining States. The University of Nevada, however, appears to have been the pioneer in establishing metal-mining schools. It opened the Vir-

ginia City School of Mines as an extension department of the University at Virginia City, on the famous Comstock Lode, in 1900. In 1905, this department was raised to the rank of a school and was placed under the State Board of Education. In this form it exists at the present time. The second industrial mining school was opened at Tonopah in May, 1915, and as a result of its success, the legislature at its last session authorized the creation of additional schools at Goldfield and Ely. These three schools are governed by the Board of Regents of the University, the Director of the Mackay School of Mines being given supervision over them. The State Board of Education has done likewise with the Virginia City School of Mines, so that the control of all four schools is centred in the mining college of the State University. Dwight P. Smith has been the principal of the Virginia City School of Mines since its detachment from the University in 1905, and has developed a system of education that has proved most successful. The entrance requirements are ability to read and write English. The school is under student self-government. The funds supplied by the State having proved insufficient to meet the requirements, the students' association charges an admission fee of \$5 and monthly dues of \$2.50. The school is open 10 hours per day in order to accommodate men working on different shifts, and the pupils are expected to attend at least 2 hours daily. Instruction is individual. The subjects taught are as follows: (1) Mathematics through descriptive geometry and plane trigonometry, (2) physics, including mechanics, heat, and electricity, (3) surveying, (4) mechanical drawing, (5) mineralogy, chemical analysis, wet and fire assaying, (6) cyaniding, (7) prospecting, involving geology, identification of rocks, field observation, rudiments of mining law, and field testing for metals.

The attendance during the last biennial has not exceeded 12 students at any one time; this appears to be due to the fact that the school has been in the camp for a long time, and the camp employs but a small number of men. In one respect this is fortunate, since the satisfactory individual instruction of a large number of pupils by one teacher is impossible.

Ellsworth R. Bennett is principal of the Tonopah School of Mines, situated at the biggest silver camp in the Silver State. The educational system at Tonopah, while resembling that of the Virginia City school in some particulars is quite distinct. There is no student self-government, and class instruction is used in place of individual instruction whenever practicable. Classes are held both in the morning and in the evening for the convenience of men working on different shifts. The laboratory is open during the afternoon. No sessions are held on Saturday or Sunday.

The total enrollment of the school has been 94 students, and the present enrollment is 31. In addition to the subjects already given it is proposed to teach drawing, surveying, prospecting, mining, and the metallurgy of silver. G. E. Hofmann has been appointed principal of the Goldfield School of Mines and V. M. Henderson of the

Ely School. Both are to be opened before June 1 of the present year. The instruction will probably be similar to that at Tonopah, with local variations to meet the special needs of the different camps. For example, at Goldfield the metallurgy of gold will take the place of silver, while at Ely the metallurgy of copper will be accentuated, since Ely is the most important copper camp in the State.

In addition to schools maintained at the more important mining centres, a movable school serving the smaller camps might accomplish good. A specially equipped car could be used as class-room and laboratory for small mining communities on the railroad, and such equipment as was necessary might be transported from it to towns at a distance. The traveling school would remain several months at each place, and its movement might be guided by advance registration at the camps desiring its service. It would also seem advisable to introduce into the United States a fifth method of educating the miner, namely to send teachers into the field to instruct men at the small mines which even the movable school would not reach. The instructor would undertake to do for the miners essentially what the agricultural extension teacher does for the farmers. The mining extension-teacher might be directed by the U. S. Bureau of Mines or by the State University, visiting mines and prospects in the order of the requests made, or going into the newer districts to impart such knowledge as would prove most beneficial. A similar system is in successful use in Canada and in other parts of the British Empire. In view of the educational assistance of this character so long extended to the farmers, it appears strange that the miners have been left without such aid.

TUNGSTEN refining as now practised by the High Speed Steel Alloys, Ltd., a corporation organized in England under advice of one of the Government war-committees, consists in mixing the crushed screened concentrate with soda-ash; this is roasted in a coal-fired reverberatory furnace for about three hours; the roasted product is boiled in water to extract the soluble sodium tungstate that had been formed by roasting; the solution is filtered off, and hydrochloric acid is added to the filtrate to precipitate tungstic oxide. This is filtered and the tungstic oxide dried, after which it is mixed with powdered anthracite coal and charged into crucibles that are heated in coke-fired furnaces. The reduced metal is washed in pans and gently dried, the final product being a chocolate-colored powder assaying 98 to 99% tungsten.

THE NAVY DEPARTMENT has issued an appeal that suggestions for improvement of storage-batteries be submitted to Lawrence Addicks of the Naval Consulting Board, 126 Liberty street, New York. Modification of the lead storage-battery or its electrolyte, tending to develop greater power for a given weight or size, as well as designs for new types of storage-batteries, more reliable and efficient than those now in use, are earnestly desired.

Mining in North-Western Arizona

By R. T. MASON

For about a year, or since the Oatman excitement began to subside, mining activity has increased in the Cerbat mountains, a district north and east of Kingman, Mohave county, Arizona. There was no United Eastern nor United Verde Extension to start a stampede to Chloride; but if there has been less excitement to mesmerize the inexperienced and the ill-advised investor, fewer failures may be expected than usually follow a mining boom. One of the productive mines in this region, the Golconda, is about 15 to 18 miles from Kingman, on the steep western slope of the range, where, looking across the Sacramento valley from the shaft, Union Pass, Secret Pass, and the peaks east of Oatman are clearly visible. The Golconda is a zinc mine operated by the Union Basin Mining Co. The stock is owned by N. L. Amster, of Boston, the majority shareholder, and by the American Metal Co. The manager is J. D. Wanvig. The ore in the main Golconda vein is confined to a high-grade streak averaging 18 in. thick, but varying from a few inches to 6 ft. or more, in lenticular shapes. On both the foot and the hanging wall is soft waste that mixes with the ore mined, thus making a milling ore averaging about 16% zinc. This metal is present as black jack with iron in the combined form, therefore not susceptible to mechanical separation one from the other.

About 150 tons per day is stoped from the 1000 and 1100-ft. levels and hoisted through the main shaft, which is an incline on the Golconda vein. At present the development is confined to the 900, 1000, 1100, and 1200-ft. levels. Sinking will be resumed when the station is completed on the 1200-ft. Ventilation is afforded by the natural passage of fresh air through the Prosperity adit, which is north of the main shaft at the 600-ft. level, thence, through the lower workings, and out through the Tub shaft near the south end of the mine.

The concentrator, situated immediately below the shaft, at present consists of two parts, a crushing and a coarse-concentrating plant, being the old Golconda mill with jigs and tables; and a fine concentrating plant which treats the tailing from the old mill together with enough from a tailing dump, containing $5\frac{1}{2}\%$ zinc, to make a feed of 200 tons per day for the tube-mills that operate in closed circuit with Dorr classifiers, thence delivering the pulp to Callow flotation cells. Plans are under way, but not yet consummated, for making changes throughout the concentrator. The machines best

adapted for the treatment of the ore are being determined by experiment. It has, however, already been decided to replace the tube-mills with Marcy mills. Water is carefully conserved. From 1200 to 1500 tons of concentrate is produced each month, containing about 42% zinc, 9% iron, 1% lead, with some silver and gold. The total extraction is 87%. The concentrate is de-

Based on 397, U. S. Geological Survey

PART OF NORTH-WESTERN ARIZONA

livered by automobile truck to the railroad about five miles distant. During 1916 the production was 11,000,000 lb. zinc, 80,000 oz. silver, and 5000 oz. gold.

From Golconda to the old camp of Mineral Park is about 5 miles across the hills to the north. Here the Keystone Consolidated Mining Co., controlled by G. S. Holmes and associates of Salt Lake City, Utah, is doing development work. Recently, F. W. Sherman, who was for many years at the Daly West mine, Park City, Utah, has taken charge. The management is pursuing a conservative and business-like policy, and has excellent pros-

pects for developing a paying mine. Driving has been done on the 150 and 300-ft. levels. Between the two the oxides change to sulphides containing iron with small percentages of copper, zinc, and lead, carrying silver. The most valuable constituent of the ore occurs as pyrrhotite, Ag_3SbS_3 , ruby silver, and probably proustite, Ag_3AsS_3 . The gangue is quartz. The vein and walls both being hard, the latter stand well, requiring little timber. A mill, in which the Fields flotation process has been installed, has been built under contract for the company. The ore would seem to be especially adapted to flotation treatment.

Not far from the Keystone the Washington and Arizona Copper Co., controlled by Elmer D. Reese, is developing its property through three adits, the lowest one, about 600 ft. long, is driven on a vein of sulphide ore valuable for its silver-content. A winze being sunk below this level is now over 30 ft. deep and said to be in ore. A second vein has also been explored in one of the upper adits and contains copper in marketable quantity. It is the expressed intention of the owners to pursue the wise policy of blocking out sufficient ore to warrant the erection of a mill before beginning its construction. The Golden Hammer, lying between the Keystone and the Washington, is being worked under lease and bond. It has ore all the way in a 400-ft. adit, and appears to be a promising prospect. About a mile from Mineral Park, near the automobile road to Chloride, on the flat just beyond the mountains, a small disseminated copper deposit, unique in character, is being worked by Kingman capitalists. A surface conglomerate-bed, stained green throughout with copper carbonate, and said to contain some sulphide and silicate, has been sufficiently prospected with test pits to justify the owners in estimating an area of 600 by 200 by 20 ft. deep, or approximately 200,000 tons, averaging 2.85% copper. The conglomerate pebbles have been identified with rocks of the mountains near Mineral Park. In laboratory leaching-tests, crushing to one-half inch, and using 10% sulphuric acid solution, a 90 to 93% saving was effected in 3 days, or 72 hr. It was found by employing air agitation that the same extraction was obtained in about half the time. A leaching plant of 100 tons daily capacity is now being erected. The ore will be excavated in an open pit and handled first by car and later by drag-line scraper. leached with a 7% sulphuric-acid solution in wooden tanks with air agitation for about 36 hr. About 80% of the copper will be deposited electrolytically with current derived from the Kingman power-plant, and the remainder, about 20% of each charge, will be drawn off and the copper deposited on scrap iron. It is thought that this proportion of fresh solution each time will prevent fouling. After the solution is drawn off each charge will be washed for about 2 hr. The electrolytic method of recovering the copper will not only save much of the acid but the water also, an important item in that vicinity. The operators are the Emerald Isle Copper Co., a corporation controlled by J. W. Cornelius, R. C. Jacobson, J. C. Stricker, and J. H. Conway, all of Kingman.

The town of Chloride, about eight miles north of Mineral Park, is the terminus of a spur leaving the main line of the Atchison, Topeka & Santa Fe railroad at McConnell, about 4 miles south of Kingman, and running up the east side of the Sacramento valley, serving all the camps on the west side of the range. The distance from Kingman to Chloride is about 29 miles. The Needles Mining & Smelting Co., a subsidiary of the U. S. Smelting, Refining & Mining Co., owns the Tennessee mine at Chloride and other mining property in the Cerbat range, and also the concentrator and smelter at Needles, California. The smelter has not been operated since it was acquired by the United States company. D. R. Muir is manager of the Needles company and the Gold Road mine in the Black range, and N. J. Churchill is superintendent of the Tennessee mine, the principal producer in the immediate vicinity of Chloride. The mine is operated through a vertical shaft to the 1400-ft. level, and a winze from the 1400 to the 1600-ft. level where driving is now in progress. About 150 tons of ore containing 15 to 16% zinc, 6 to 8% lead, 28% iron, and \$7 in gold and silver, is hoisted daily from the stopes above the 1400-ft. level. The vein dips easterly from 78 to 80°, except between the 900 and 1200-ft. levels, where it turns over to 75° westerly. The ore lies between a granite-schist foot and a pegmatite hanging wall, and is always associated with the latter rock. It assumes lenticular forms, usually one orebody being directly above another and sometimes separated by only a few feet of gouge. The ground is heavy and costly to timber. Square sets are employed, the stopes being filled as the work progresses, and spiling is frequently needed. The cost for timbering is 78c. per ton. Wages for underground work range from \$4 to \$6; contracts are let on development work; and the bonus-system is used in all cases.

The ore is shipped by way of the Santa Fe railroad to the concentrator at Needles. The zinc in the Tennessee ore occurs both as black-jack and as the resinous variety. On account of its habit of excessive sliming the tailing formerly contained 8% zinc, but this has since been reduced to 2.5% by the introduction of flotation. The tailing now contains about 0.1 oz. gold, 0.6 oz. silver, 0.1% lead, 2.5% zinc, 5.7% iron, and 77% silica.

The Schuykill adjoins the Tennessee on the north and, like many others in the district, it is an old mine re-opened. The 700-ft. level has been reached, and it is reported that sinking will be continued to the 1000-ft. level. A few cars of ore have been shipped. The Elkhart lying farther north of the Schuykill is another old mine of the district, re-opened and in process of development. The Stockton Hill section, lying on the east side of the Cerbat range, and about east of the old town of Cerbat, is sharing in the general activity. Two of the best known properties are the Wrigley group, and the Arizona-Butte, which is now operating a mill. Most of the ore in the entire Cerbat district requires concentration to be marketable and water for the purpose is scarce, but the mills in operation seem to have sufficient by using water-saving appliances.

Concentrates

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

MILL FOREMEN should frequently go over the main-line and counter-shafting in the mill to see that it is in line. Timbers shrink and warp with time, and the boxes carrying the shafting move with these changes of position in the timbers, greatly increasing friction and even resulting in the breaking of a shaft.

COMPRESSED-AIR requirements for flotation in the Cal-low cell, used in many concentration-mills, are 130 cu. ft. of free air per minute at 5 lb. pressure, the treatment-capacity of a cell averaging about 50 tons of solid in the pulp per 24 hr. Expressing it otherwise, there is needed 2.6 cu. ft. of free air per minute at 5 lb. pressure per 24-hr. ton.

Scheelite when found in pegmatite veins is frequently associated with fluorite, molybdenite, and wolframite. In such cases it is not uncommon for some of the tungsten in the scheelite to be replaced by molybdenum. As these two substances are difficult to separate in the practical operation of refining the scheelite is reduced in value accordingly.

Marmatite is a variety of zinc blende containing large amounts of iron, sometimes exceeding 10%. The iron is present as the mono-sulphide (FeS). The mineral is often highly lustrous, with a metallic reflection, and its color ranges from deep black to brown. When pulverized the powder is magnetic, dependent upon the amount of the ferrous iron that is present.

WATER AND HEAVY AIR-PIPES in mines, particularly in shafts, should be connected at every other joint, by flanges instead of the usual couplings. The flanges give a good substantial bearing for yokes or other means of support to the pipe, and they also permit repairs or changes to be made without disconnecting long lengths of pipe, or of resorting to cutting the pipe.

In our issue of April 14 it was stated on this page that a long pipe would empty a reservoir more quickly than a short pipe. This was wrong. The formula is:

$$h = f \frac{lv^2}{d2g}$$

The loss of head in friction is directly proportional to the length of pipe; if you double the head you double the friction.

MULTIPLE-ARCH dams of medium height cost less to construct than rock-fill dams, especially if the latter are provided with anything better than a wooden up-stream face as a water-tight cut-off. The stresses and dimensions in a multiple-arch dam can be accurately calculated, so that the factor of safety is ascertainable within

narrow limits. In case of floods, when water may overflow the crest, a dam of this design will not be injured. Details concerning the design and construction of this relatively new type of dam are given by L. R. Jorgensen in the Proceedings of the American Society of Civil Engineers for March, 1917.

ONE CAUSE of the large amount of water coming from the cylinders of hoisting-engines is that ordinarily hoisting-engines are employed intermittently. During the periods of idleness steam condenses in the piping connecting the boiler and engine-cylinder. This condensation can be minimized by covering the steam-pipe with a thick non-conducting material such as magnesia or asbestos-packing.

GRAPHITE occurs in both igneous and sedimentary rocks. The origin of the veins is not well understood. Some geologists believe that they may have been derived from the gaseous constituents of the magma. Below 500° C. a reaction will occur between carbon monoxide and hydrogen, forming carbon and water-vapor. It is thought that the deposits in Ceylon, and at Ticonderoga, New York, were formed in this way.

SCALE IN BOILERS is composed mainly of carbonate of calcium and magnesium, and the sulphates of these metals. Less frequently are found iron carbonate, magnesium chloride, calcium chloride, potassium chloride, and sodium chloride. Mud also causes scale, but this can be prevented by filtering the boiler-water. Never use an acid water in a boiler. The acid must be neutralized by adding an alkali to the water before it enters the boiler. Carbonate of soda is a good neutralizing agent, if not used in excess.

STAMP-GUIDE TIMBERS of a stamp-mill require close attention. The jar from the stamps causes the stems to wear the wood, until the guides become loose. Often the guide-timbers are in two sections, and wedges are placed between. As the guides wear, the wedges are reduced in thickness from time to time, permitting the guides to come closer to the stems, keeping them at a proper distance. When the guides wear so as to allow too much movement to the stem, the shoe is likely to strike the die a glancing blow, and may cause the breaking of a stem.

RUST can be cleaned from corroded iron and steel plate and machinery by applying to the surface so affected a moistened mixture of two parts of pulverized sodium bi-sulphate and one part of common salt. The operation may be hastened by scraping off the mixture every two or three hours, brushing the surface with a wire brush, and then re-coating with the anti-corrosive material. The plate should be clean within 24 hours. Wash well with a solution of soda-ash, dry quickly, and then coat with paraffine oil to protect the surface from oxidation. This method is more effective than hammering, chiselling, or cleaning with a sand-blast.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

PACKARD, NEVADA

CONSTRUCTION OF MILLS UNDER WAY AND NEW PLANTS BEING PLANNED.—RAPID DEVELOPMENT.—PROSPECT OF MINING LITIGATION.

With the melting of the snow increased activity is noticeable in the Packard district. A stage-line is now in operation between Rochester and Packard, making four trips daily, and a post-office will soon be granted to the town. Delay in its establishment was due to the refusal of the postal department at Washington to accept the name of Packard for the camp, due to its duplication in other States.

Grading for the 300-ton mill of the Rochester Combined Mines Co. will be commenced before May 1. The contract for its design and erection was given to K. Freitag, who designed and built the Packard mill, a half mile from the site of the new mill. In general the flow-sheet will follow that of the Packard. Crushing will be done by a 7½ Teismith crusher. Rolls are to be eliminated, the 2-in. product from the crusher going to 6 by 5-ft. ball-mills using 5-in. balls; re-grinding in 7 by 10-ft. pebble-mills in closed circuit with Dorr classifiers. Dorr agitators and tray-thickeners will be used, followed by Oliver filters, precipitation to be by Merrill presses. Electric power will be used, the power-lines having already been brought in. The mill will be built in two units of 150 tons each, to be completed and in operation by November 1. Provision will be made for the addition of a flotation-unit to treat tailing if increasing quantities of sulphide in the ore should justify it. The value in the ore so far opened consists almost entirely of hornsilver.

The flow-sheets of the two mills now operating in this district differ radically. The Rochester mill uses heavy stamps, with straight counter-current decantation and zinc-thread precipitation, whereas the Packard uses modified counter-current decantation, followed by filtration and zinc-dust precipitation. The same management controls both the Rochester Mines and Combined Mines, so that their decision to eliminate stamps and add precipitation-presses and filters is interesting.

The big contact orebody on the Shepherd claim of the Combined Mines is being rapidly developed. The upper adit has followed the vein to within a few feet of the Packard end-line. The main working-adit recently cut the orebody over 200 ft. below. The contact has been opened up at several points between there and Rochester and some low-grade ore developed. Ore will be delivered to the mill from the outlying claims by electric-haulage. Over 50 men are now employed. The development and equipment of this property has been spectacular, to say the least. Within a few weeks in December the 80 claims were purchased and surveyed. At that time assessment work constituted practically the only development. A compressor driven by a Diesel engine was installed in January and work was begun on the various parts of the property. Nine months after the first man was put to work, the company expects to be treating 300 tons of ore daily in its own mill.

The increase in the capacity of the Packard mill from 100 to 150 tons daily will probably be secured by the addition of tray-thickeners and by some changes in the grinding-units. Development work on the property during the last few months has fully justified the increase. The 120 tunnel has been driven for over 900 ft. along the contact orebody. It

will be rapidly advanced to cover the remaining 400 ft. to the end-line, where it will connect with the lower tunnel of the Combined Mines. Work is being started on a series of raises to make available for milling large bodies of surface ore opened up by lessees in the early days of the camp. Prospecting of the belt of silicified rhyolite lying east of the 'dike' outcrop will be begun soon.

The discovery of rich ore on the 800-ft. level of the Rochester mine is encouraging. This represents deep mining for this district. The Rochester Mines company probably will have its new aerial tramway in operation before May 1. The mill is running steadily at full capacity.

The Nenzel-Crown Point property is preparing for the erection of a 150-ton cyanide-plant. Designs for this mill also are being drawn by K. Freitag. It is probable that a combination of flotation and cyanidation will be used. Unlike the other ores in the district much of the ore from the Crown Point is sulphide, containing a higher proportion of gold than the average of the district.

There are persistent rumors to the effect that the Merger will begin an apex-suit in the near future against the Rochester Mines Company. With the complex systems of faulting in this district such a suit holds interesting possibilities.

OATMAN, ARIZONA

STOPES STARTED IN THE UNITED EASTERN.—NEW ELECTRIC MACHINERY INSTALLED.—MILL OPERATION SATISFACTORY.

During the month of March the United Eastern Co. milled 6584 tons of ore, of an average value of \$23.84 per ton, and a total gross value of \$156,962.59. The mill made a recovery of 96.15% of the value.

Stoping is under way on the 465 and 565-ft. levels, where widths up to 40 ft. are being mined. Two benches of square-sets are being erected on each level, but above these the stopes will be worked by a variation of the cut-and-fill system. On the 665-ft. level the cross-cut from the main shaft has made connection with the drift from the old shaft, and the bottom of the drift is being cut to adjust the grade.

Preparations for resuming sinking at the main-shaft are under way. A single-drum electric hoist, 37½ hp., has been erected at the 665-ft. station. A heavy bulkhead has been built under the main hoisting-compartments and the sinking will be done through the third compartment. It is planned to sink an additional 300 ft., after which the first cross-cut will be driven to the vein at the 965-ft. level. Below the 665-ft. level the drifts will be run at vertical intervals of 150 ft. No exploration work is being done. The large amount of work on the sill-floors while cutting out the stopes makes development work impracticable at this time. However, during the preliminary stope-work, branches of the vein have been opened in the walls of the 465 and 565-ft. levels, which have increased the quantity of ore blocked out considerably above that estimated during the period before stoping began.

The mill has been operating satisfactorily. A few minor changes have been found necessary since milling was started, principally for the purpose of securing finer grinding than was at first possible, and 90% of the ore is now being ground fine enough to pass through a 200-mesh screen. The average daily tonnage for March was 212.5 tons. The future supply of cyanide for milling operations has been taken care of, and

from this time forward there appears to be no likelihood of a shortage.

A decided improvement is reported in the Gold Ore mine, at Gold Road. At 50 ft. depth in the winze, at 580 ft. from the surface, the vein is 6 ft. wide and recently has averaged over \$300 per ton. There is a streak of white quartz liberally sprinkled with gold. Last summer the company milled 2000 tons of ore at the Gold Road mill that averaged \$14.50 per ton. The plan is to build a mill this year.—Development in the Gold Road Bonanza has brought the working close to the main vein in following a spur vein on the 550-ft. level. On the 250-ft. level the main vein is 60 ft. wide and is said to average \$3.10. It is expected that the value of the ore will be higher at 550 ft.—A stockholders meeting of the Big Jim Gold Mining Co. was held at Phoenix, Arizona, April 24, to ratify the action of the directors, on April 4, in selling the Big Jim and Monarch claims, comprising the Big Jim mine, to the United Eastern Mining Co. On May 1 the mine will be turned over to the United Eastern, and A. G. Keating, the superintendent, will take charge of the Big Jim Consolidated, successor to the Big Jim Gold Mining Co., and start the development of the Bluebird property. Three shifts will be employed and the shaft will be sunk from 240 ft. to a depth of 600 ft., where the vein will be explored. The annual meeting of the Tom Reed Gold Mines Co. will be held on April 30, at Kingman, Arizona, for the election of directors and the discussion of the affairs of the company. The reconstructed 300-ton cyanide-mill will be in operation about May 1. The new board of directors will visit Oatman and inspect the underground workings.

AUSTIN, TEXAS

TEXAS HAS MANY DEPOSITS OF VALUABLE AND USEFUL MINERALS.
SULPHUR AND QUICKSILVER ARE IMPORTANT.

William B. Phillips, former director of the Bureau of Geology and Technology, of the University of Texas, has just finished making a preliminary survey of the mineral resources of the State. He says that Texas can supply graphite, molybdenite, petroleum and its products, quicksilver, copper, iron, silver, and sulphur in almost unlimited quantities for the nation's needs. The production of graphite of the flake variety has not yet assumed large proportions, but there are two mills in the State now equipped for the making of what is known as '55' graphite, flake graphite containing from 50 to 55% graphite, which is much used in foundries and machine-shops. These are the mills of the Texas Graphite Co., nine miles West of Burnet, and the Dixie Graphite Co., five miles north-east of Llano. These mills can now grind and concentrate about 25 tons each per day of the crude material. The yield of graphite from this material is from 8 to 10%. With the expenditure of a few thousand dollars these mills could produce a much better grade of graphite than they do now. On the property of the Dixie Graphite Co. there has been uncovered a vein of molybdenite. On Honey creek, in Llano county, molybdenite occurs with native bismuth and some prospecting has been done there of late. Molybdenite also occurs in the Quitman mountains.

The petroleum production during the two years ending with 1916 was 40,000,000 barrels. There are now in the State nineteen oil-refineries with a total combined daily still-capacity of 218,000 barrels. There are three other refineries not now in operation, but within a short time the daily capacity of all the refineries in the State will be about 140,000 barrels. Of the refineries in operation five are situated on tidewater, or on canals connected with tidewater, at Beaumont, Port Arthur, Port Neches, and Texas City. These five refineries have a daily capacity of 130,000 barrels. The principal refineries in the State are connected by pipe-line with the wells in Texas and in the Oklahoma fields. The guarding of the refineries and pipe-lines will have to be undertaken, possibly by State

troops. Texas is now, and has been for several years, the second largest producer of quicksilver in the country. The mines and furnaces are in the southern part of Brewster county, not more than two hours' ride from the border. The total value of the quicksilver produced in the State is now close to \$3,000,000. The ores are much richer than the average Californian ores, although California produces a great deal more quicksilver than Texas does.

There is but one producing silver mine in the State, that at Shafter, in Presidio county, but it has been in successful operation for 30 years. The total value of the product is close to \$8,000,000. This mine is within 20 miles of the border.

The situation with respect to sulphur is particularly interesting. At Freeport, at the mouth of the Brazos river, there is a large deposit of sulphur worked by the Freeport Sulphur Co. The sulphur-bearing beds lie from 1000 to 1200 ft. below the surface and are worked by forcing super-heated water and steam down through pipes. This melts the sulphur and by pumping it back, the sulphur runs out of the pipe as liquid sulphur and is carried to open-air bins and allowed to cool. There are large piles of pure sulphur from which the railroad cars and vessels are loaded.

The plant here is extensive and represents a large investment. In Culberson county, south of New Mexico, there are deposits of native sulphur associated with gypsum and disintegrated limestone. In the aggregate there is a great deal of sulphur in this district, but systematic development is lacking. On one of the sulphur properties in Culberson county, in Maverick Springs district, 20 miles west of the Santa Fe lines at Orla, Reeves county, some development work has been done by the Michigan Sulphur & Oil Co. and from 200 to 300 tons of excellent sulphur has been produced. The sulphur is extracted from the ore by means of super-heated water and steam. The mine-cars are run into a large steel cylinder, this is then tightly closed and steam under a pressure of 40 to 50 lb. is admitted, the sulphur is melted, and is then tapped from the bottom of the cylinder, when the operation is repeated. The present production is small, the capacity of the plant not exceeding 10 to 15 tons of sulphur per day, even when the best ores are used.

Texas produces so little copper, lead, zinc, and gold that these items are not of much consequence. No pig-iron at all is produced, though there are excellent resources in these metals, with the exception of gold, but they are at present not utilized. There are tin ores in the Franklin mountains, near El Paso, but nothing has been done there for some years. In the Quitman mountains, 80 miles south of El Paso, there are some deposits of wulfenite (molybdate of lead), as also of tungsten ores, but they have been utilized to a very small extent.

SUTTER CREEK, CALIFORNIA

A NEW INDUSTRIAL ENTERPRISE PREPARING FOR BUSINESS.—A NOVEL METHOD OF TRANSPORTATION PROPOSED.

The California Clay Corporation is having plans prepared for the plant to be erected at Ione for the manufacture of fire-brick and other products, and grading for the new buildings will begin shortly. Manager A. S. Cunningham is in the East, arranging for the shipment of the necessary machinery and equipment. The proposed plant is to have a capacity of 3,000,000 bricks annually and will cost approximately \$65,000. This company has secured a 50-year lease on 30,000 acres in the Arroyo Seco grant, which contains one of the largest clay deposits west of the Mississippi. Local capital is interested in the enterprise and the following men have been chosen as officers for the first year: Geo. C. Hallerton, president; A. S. Cunningham, vice-president and general manager; James R. Keith, secretary; and E. V. McGinto, treasurer.

Another important industry in course of development at Ione is the mining and refining of glass-sand and kaolin

suitable for the manufacture of chinaware and porcelain, this work being carried on by the Theo. Dittell company. Theo. Dittell is president and local manager, and W. D. Amick and other local men are interested in the project. The sand, clay, and kaolin will be mined on the ranch formerly owned by N. Clark & Sons, where 14 men have been put to work at stripping, and developing the deposits for shipment, and shipping will commence about May 1. Plans have been made for the construction of a plant at Carbondale, near Ione. The material when mined will be piped from the pits to this point, a distance of about $1\frac{1}{2}$ miles. Operations at the mine are being rushed in order to begin the shipment of white sand to San Francisco, where a firm has contracted for the delivery of 10,000 tons per year for the next five years. This sand is regarded by manufacturers as of the highest grade and not below the finest quality of English sand. It is to be used in the manufacture of white bottles. The new company is said to have abundant financial resources.

The Drytown Consolidated Gold-Mining Co., organized to take over the Crown Point quartz mine, near Drytown, has filed its articles of incorporation with the county clerk of Amador county. The capital stock of \$50,000 is divided into 500,000 shares of a par value of 10c. per share, and each of the following trustees has subscribed for ten shares: R. R. Moore, Oatman, Arizona; G. C. Dickerman and Chas. R. Lombardo, Drytown, California, and J. W. Caldwell, Sacramento. This property was formerly owned by Mrs. M. E. Fontenrose of Jackson.

Cleaning out the bottom of the shaft and renewing timbers where necessary in the drifts and cross-cuts is still in progress at the Old Eureka mine at Sutter Creek. The new hoisting-machinery and equipment have not yet been put into use, although everything is about ready for operation.

HOUGHTON, MICHIGAN

COPPER STOCKS AND WAR PRICES AS THEY AFFECT SHAREHOLDERS IN THE LAKE REGION.

Lake Superior shareholders of copper are expecting a radical reduction in the price of copper, probably down to 20 cents for deliveries during the last six months of 1917. The prices now are the highest they have been since the Civil War, and the mines of the Lake Superior district are sold ahead until August, and some beyond that date, at prices averaging better than 28 cents a pound, the highest figure reached, for a great amount on future delivery, since the European war started. But the contracts with the allied governments for delivery during the last quarter of 1917 have not yet been made. The concession to the Government of 16 cents, made by the producers, was applauded by shareholders more enthusiastically when they saw that it meant only about three per cent of the copper output, but the average Lake Superior shareholder in copper stocks now has convinced himself that, if the producers made these concessions for the benefit of the United States government, some radical concessions must now be made to the Allies of the Government of the United States, because the success of the Allies is quite as much a matter of necessity to this country as to England. They assume, then, if 16-cent copper is given to the United States Government, a substantial reduction from 28 cents must be made to the Allies. It does not follow, however, that a similar reduction will be made to domestic consumers, but it is difficult to see how such a thing can be avoided, in the opinion of those usually well informed. The Lake Superior shareholders look upon this as a result of the participation of the United States in the world's war and are reconciled to make the contribution from their dividends, which have been unusually high since the War began. As far as the stock-market value of shares is concerned, a realization of this fact is not looked upon as a bearish argument, for none of the Lake Superior stocks have shown an advance in pro-

portion to the earnings, and practically all are now selling on a 15-cent metal basis.

The Calumet & Hecla company now operates six shafts on the old Osceola lode. Four are down below 3000 ft. and two close to 2000 ft. deep. One-third of the product comes from foot-wall stopes. Advance openings give assurances for three years' work ahead on a grade of rock equal to that now coming out. In fact, the lower openings are showing a slight improvement in quality. The lode is irregular and sometimes runs as wide as 140 ft. with copper carrying at both the foot and hanging. Driving in the Osceola-lode shafts will exceed 18,000 ft. this year, at the present rate of advancement, compared with the high record of 16,000 ft. last year.

There is little hope of a material advantage from Lake shipping-rates for copper this spring, as navigation will be at least two weeks late in opening. As a matter of fact practically no copper is on hand at the smelters here, a condition decidedly unusual. The local copper mines expected to take care of their coal-shortage by early shipments, but coal has been coming in by rail for several weeks.

PORCUPINE, ONTARIO

PORCUPINE DISTRICT.—LABOR SITUATION ACUTE.—COBALT DISTRICT.—MINERS DEMAND HIGHER WAGES.

The Porcupine district is facing its first real crisis in its history. The labor situation daily is growing more acute. Not only is labor scarce, but it is most inefficient. Day by day the inefficiency of the mine-workers becomes more evident. Costs at every mine are now on an upward trend. This is due largely to the indifference and the inefficiency of labor, and in a lesser degree to the increasing cost of mining supplies. About 50% of the mine-workers are first-class workmen, but the remaining half are not more than 50% efficient, thereby undermining the effectiveness of the entire working-force. At present there would appear to be no remedy other than to curtail operations until the end of the War. A few weeks ago the curtailment of operations at the gold mines would have brought forth a torrent of criticism, in that at that time every ounce of gold was urgently needed to maintain war-credit in other countries, especially in the United States. The situation has now changed to such an extent that gold mining is of secondary importance. The change is due to the entry of our big southern neighbor into the conflict. By opening her immense resources to the credit of the Allies she has made it possible for every allied country in the world to curtail the mining of precious metal without seriously placing their credit in jeopardy. Whether or not such a development takes place universally remains to be seen, but such would appear to be the probability at least for Porcupine. Just now the mine-workers of not only Porcupine but also of Cobalt and Kirkland Lake are on the verge of asking for an increase of 50 cents per day. This will probably come in the form of a demand, and the burden, already heavy, would thus be increased something like one million dollars annually. The mine-managers have stated that the increase will not be granted. The mine-workers have intimated that the demand will be made. The situation has thus reached a crisis, the issue of which will probably be decided on May 7, at which time the mine-workers will hold their annual convention at Cobalt.

From a well informed source come rumors that the Government will take action to prevent the closing-down of the precious-metal mines of Ontario; that the Militia Act will be enforced, and that the mine-workers may then withdraw their demand. Unfortunately for the districts affected, mining men do not share such views, but believe that the Government would take advantage of the situation by recruiting men for the army, diverting others to agriculture, and to the work of manufacturing munitions.

At Cobalt, as at Porcupine, mining operations are being con-

ducted under the shadow of an impending strike. With the price of bar-silver above 70c. per ounce, however, the operators are doing everything in their power to forestall the miners in their threat of a demand for increased pay. To grant the increase would be a recognition of the union. As yet, the W. F. M. is not recognized in this part of the Dominion. The managers accordingly are paying a bonus of 50c. per day when silver is above 70c., and offer to pay 75c. when silver is above 80c. The plan has not met with favor among the workers, in that it does not better the position of those in the gold districts; moreover, whether the price of silver is high or low they must be assured a living-wage. This issue also will probably be decided at the annual convention in May.

The shipping of bullion from the Nipissing high-grade mill has been resumed after a few days, the stop being due to a shortage of oil. Last week Nipissing and the Mining Corporation of Canada shipped an aggregate of nearly \$200,000 in bullion. In addition to this, nine cars of ore was shipped during the week.

The Mining Corporation recently shipped one car of ore from which 241,000 oz. silver was recovered, valued at \$177,000. This is the most valuable car that has ever left Cobalt. Formerly the Temiskaming held the record, having about a year ago sent out a car containing 250,000 oz. The lower price of silver at that time, however, made the car worth approximately \$150,000. At present prices the car would be worth \$180,000.

Mining operations on the 1600-ft. level of the Beaver Consolidated is meeting with satisfactory results. Now, that these lower contact workings have been connected with the Temiskaming, development is being pushed. Remarkably rich ore is being mined from the winze at that depth, and the condition of the mine is generally greatly improved.

In the Kirkland Lake gold area the main shaft of the Kirkland Lake mine has reached the 600-ft. level, where a cross-cut is being driven for the purpose of cutting the main vein, which on the upper levels contained high-grade milling ore. This cross-cut should reach the vein within the next few days. The result of the operation will have an important bearing on the future of the camp, as this is the deepest work thus far in the district. Hitherto, the Tough-Oakes mine held the record for depth, having conducted considerable development on the 500-ft. level. During 1916 the Tough-Oakes produced \$707,000. Now that the 65-mile electric-transmission line is completed, this mine is expected to produce about \$1,000,000 during the current year. In the litigation between C. A. Foster, president of the company, and some of the English interests, the former has lost the first round; judgment, as handed down by Mr. Justice Kelly of Toronto, going entirely against Foster. An appeal is now to be taken, a stay of judgment having been extended meanwhile.

There has been an increase of activity in the Kirkland Lake district since the electric-power was turned on. Operations have begun on the Sylvanite claim, where several promising veins are showing on the surface. A shaft is being sunk to 100 feet.

BONNE TERRE, MISSOURI

UNUSUAL ACTIVITY AND ADVANCING WAGES.—OLD PLANTS REMODELED AND NEW ONES BEING BUILT.

The advancing price of lead has resulted in great activity in this district. The past year witnessed the largest output of lead in its history, and labor is now receiving the highest wages ever paid here. During 1916 the workmen received a 30% bonus on their regular wages. On February 1 this was increased to 40%, and on March 1 it was further increased to 50% and the second check, or bonus discontinued.

A serious coal-shortage occurred in the latter part of December, and the Federal Lead Co. was forced to shut-down for several days. Relief in the severe cold weather occurred

and allowed the delayed shipments to reach the mines in time to prevent further shut-downs. The new mill of the Federal Lead Co. began operation early in January. This is the first new plant to be built in the district in several years. It is constructed entirely of concrete and steel and has been built in record time, being ready for operation eight months after construction started. Its capacity will be about 2500 tons. The new power-plant of the Doe Run Lead Co. is about completed and will start operating this month. This is a turbine-plant of 6000-hp. capacity, with the building constructed of brick, and modern in every respect.

A large amount of construction work is being done in all the mills of the district. New machinery is being tested with a view to securing a general improvement in operation. Ball-mills are being installed and tested for still higher recoveries.

The companies are all making arrangements for impounding the slime in settling-ponds instead of allowing it to run into Big river. Some of the ponds are completed and in use. At the Bonne Terre plant of the St. Joseph Lead Co., a large dam for the settling-pond has been built of 'chatt' from the mill. All the companies formerly allowed the slime to run into Big river, but the farmers in the district brought suit and recently won a court decision that compels the companies to stop this practice.

In the Fredericktown district the Catherine property and the old Mine La Motte, or Missouri Metals Co., as it is now called, are operating at full capacity. The Missouri Metals Co. is remodeling its mill, and the old North American Co. is practically re-building the entire plant of mines, mill, furnace, and refineries, and will shortly be operating, producing lead, copper, zinc, nickel, and cobalt.

NEVADA

NEW DEVELOPMENTS AT GOLDFIELD, MANHATTAN, NIPTON, AND AT SWEETWATER.

A block of ground 650 ft. long by 135 ft. wide has been leased from the Jumbo Extension by the Goldfield Consolidated and the production of copper-gold ore has been started for the flotation-plant. The ground adjoins the Clermont mine and is worked from the 710-ft. level. A small shoot of bonanza ore was discovered here a few days ago. Ore for the flotation-plant is at present coming principally from the Laguna, Mohawk, and Red Top mines, but within a short time 100 tons will be treated daily for the Atlanta Co. Until a large and dependable supply of flotation-ore has been assured the company will operate only one 500-ton unit. Lessees are sending considerable ore to the cyanide department of the mill, with some high-grade ore coming from the Mohawk and Red Top.

The recent discovery in the Jumbo Junior at a depth of 880 ft. is stated to be developing well. The vein has been intersected at two points, 50 ft. apart, and has widened from two to three feet. It is planned to start early shipments to the Goldfield sampler. The ore is stated to assay from \$50 to \$290 per ton in gold and silver and the vein is trending toward the Lone Star.

The Silver Pick Co. is making a final effort to find profitable ore west of the Columbia Mountain fault. From the 1100-ft. level extensive cross-cutting and driving is proceeding, and the vein-material is said to show small quantities of gold and copper. Core-drills indicated the presence of profitable ore in this territory last fall.

With more than 20 companies active the Manhattan district is one of the busiest in Nevada. Operators are planning a stock-exchange, and the construction of new buildings has been ordered, including a large hotel. Many old properties that have lain idle since the collapse of the first excitement are being rejuvenated, and some attention is being paid to the copper deposits found outside the gold-bearing belt.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ARIZONA

SANTA CRUZ COUNTY

J. H. Verfuth is operating the Wandering Jew mines in the Tyndall district in the Santa Rita mountains. A new road to the mines has been completed, and the mill has been removed from the Salero Flat to the mine. The ore now goes directly from the mine to the rock-breaker and thence to the stamps. Formerly the ore was packed down the mountain by animals on a trail. The mill is being enlarged and additional machinery placed. A new vein of rich lead-silver ore has recently been developed, and the Wandering Jew soon will become a steady and profitable producer.

YAVAPAI COUNTY

The Loma Prieta property comprises 498 acres (27 claims) located in the Copper Basin district, about 12 miles west of Prescott.

The property is within six miles of the railroad at Skull Valley, which is reached by wagon-road. The smelter at Humboldt, 40 miles from the mines, affords a good market for ore and concentrate. Adjoining this property and interlocking with it is the Commercial Mining Company's property, controlled by Phelps, Dodge & Co., and from which 50 to 100 tons of ore per day is being mined and shipped. The buildings consist of a shaft-house, machine and blacksmith-shop, and boarding-house. The property is equipped with heavy hoisting-machinery, 60-hp. boiler, pumps, Leyner compressor, drills, and all equipment necessary for the present operations.

The main shaft is down 420 ft. and is being rapidly pushed to the 500-ft. level. A station was cut at 390 ft. and driving is in progress. The shaft has been in pay-ore from a depth of 62 ft. to the present depth. At the 140-ft. level two drifts were run in opposite directions with cross-cuts for 200 ft. The drifts at the 400-ft. level are in ore running from 3% to 5% copper for over 80 ft., while ore assaying over 20% in copper and \$1.60 in gold and silver is being opened up in increasing quantities. A. B. Peach is superintendent of the Loma Prieta mines and for seven years was superintendent of the Phelps-Dodge property, immediately adjoining the Loma Prieta.

CALIFORNIA

CALAVERAS COUNTY

(Special Correspondence.)—The Drake group of claims, including the Last Chance mine, just south of Angels, is to be unwatered and worked by Eastern people. The old shaft is over 1400 ft. deep and it is reported orders have been placed for hoisting and pumping-machinery. The Drake property covers the largest area of any in the Angels field.

A small test-mill is being erected at the Calaveras Consolidated mine, rejuvenated by W. J. Loring and associates. The mill will be followed by a large plant as soon as the best method of treatment has been determined and sufficient ore is available. Driving of the main adit is proceeding rapidly with much good ore reported.

The Lightner mine has been examined by Alex Chalmers and Short & Langham of San Francisco, and it is said work will be resumed. The Allison, Dolling (North Star), and other old producers are being examined in the interest of San Francisco people.

It is reported that good ore has been struck at a depth of 800 ft. in the Tullock mine, on Albany Flat, which is being

operated by the Lane interests. The ore is of milling-grade and plans are said to be under consideration for erection of a mill.

The Utica Mining Co. is operating its Gold Cliff and Utica mines and keeping both mills running at full capacity. Developments in the Gold Cliff are reported as particularly satisfactory.

The Levensaler-Speir syndicate of San Francisco is working a number of chrome and manganese claims in the southern end of this county, and also in Tuolumne. Several properties are stated to be about ready for small shipments. Fred Walker is manager.

Angels, April 26.

MARIPOSA COUNTY

A number of men lost their lives in the Mountain King gold mine, several miles above Bagby, near the Merced river on April 29. It is stated that the accident was due to the shutting off of the power, caused by the breaking of the ditch or flume carrying water to the power-plant. Press dispatches stated that the men were overcome by foul air, and were unable to escape from the mine workings. The night-shift worked on the 1400-ft. level of the mine as usual, and fired a round of holes on coming off shift, at about 3 a.m. Sunday morning. A number of men of the day-shift were sent to repair the broken flume, and several others were directed to go into the mine and make some repairs to the track on the adit-level. They were warned against going below the adit-level, as it was thought the bottom of the mine was filled with gas from the blasting during the night. Ignoring these instructions, some of the men climbed down the ladders to the 1400-ft. level, and as a consequence were asphyxiated by the deadly gas that filled the bottom of the mine.

As quickly as possible the flume, which had been torn out to make the necessary repairs, was replaced and the water turned in again. This supplied the necessary power for ventilating the lower workings. Meanwhile, every effort was made to rescue the men who had been suffocated by the gas, and some of the rescuers themselves were overcome and in turn had to be rescued. Finally, by the use of helmets the bodies of seven men were recovered and brought to the surface.

The mill at the Mariposa mine will soon be crushing rock taken out by those working around Mariposa under leases from the company. It is reported at Mariposa that the Mariposa Grant has been sold to Eastern men.

MONO COUNTY

(Special Correspondence.)—A promising discovery of molybdenite has been made seven miles east of Masonic by Amigo & McLean, and shipments are being made to Eastern steel-mills by way of Hazen. The ore is high-grade and several claims have been located on the strike and prospecting has begun.

A silver-gold vein 8 ft. wide has been intersected by the adit on the Silverado claim of the Nevada Progressive Co. Assays average around \$100 per ton. Thomas Hobb, engineer in charge of the Western Pacific survey of Beckwith pass, has been retained as consulting engineer. Construction of the mill is about to start.

The Masonic Gold Mining & Reduction Co. is driving an adit to intersect the main orebody and has arranged for extensive summer operations. L. J. Cockburn, of Denver, is president and general manager, and Frank Strohm is superintendent.

Masonic, April 28.

NEVADA COUNTY

(Special Correspondence.)—The new 10-stamp mill of the Columbia Consolidated Mines Co., 3 miles above Washington, is running steadily on ore averaging \$7 per ton, and crushing 35 tons per day. The vein is from 2 to 10 ft. wide but the ore contains about the same value throughout, the varying width of the vein seeming to have no important effect on it. The shaft has reached a depth of 300 ft. and is to be sunk to 500 ft. A compressor is run by water-power, direct, all other machinery being run by electricity. A new electric hoist has arrived at the mine and will be put in place at once. The company built a mill last summer but it was scarcely completed before it took fire and was entirely destroyed. The mill now on the property was built immediately after the fire and is to be enlarged by the addition of 10 more stamps. The ore is practically free-milling, as it contains only a small amount of sulphide, and as this is worth only \$25 a ton no effort is made to save or treat it as concentrate. E. C. Klinker is managing director and general superintendent. The property is owned by Honolulu capitalists.

Nevada City, April 26.

It is reported that representatives of the North Star mine, of Grass Valley, are examining George Rogers' prospects in Brandy Flat, a short distance west of Washington. These prospects have shown up well, and good rock has been taken out.

Joe Foise & Co. are working nine men at the mouth of Poorman's creek, one mile below Washington. They have a machine to work over the old tailing of the Forty Nine hydraulic mines at Red Point, and are also driving an adit into Red Point.

PLUMAS COUNTY

The difficulty of getting supplies into the Robinson mine at Granite basin has caused the camp to be closed until the roads are opened for easier transportation. Operations on a large scale are expected this summer. The roads are seldom passable before the middle of June, and last year the ice and snow had to be blasted out in some places early in July, in order to get machinery to the mine.

RIVERSIDE COUNTY

The final payment of \$15,000 on the Horn mine was paid into the Commercial Bank of Parker last week to the credit of the former owners of that property, J. E. Kelton and Michael Horn, says the *Parker Post*. The total purchase price, it is said, was \$25,000, \$10,000 having been paid to the owners in previous payments. It is understood that a large development fund has been placed in the treasury. Extensive work has been started at the property, and from the showing developed to date the Horn property has every indication of becoming a steady producer of copper within a few months.

The company was organized by W. H. Tharpe six months ago; and through his persevering efforts it is now successfully financed.

SAN BERNARDINO COUNTY

The following notes are from the *State Miner*, of Randsburg: Several hundred men are rushing the construction of another million dollar borax and potash-plant with two 500-kilowatt steam-turbines at Trona.

Work has commenced on manganese properties near Ludlow by lessees. It is one of the biggest known manganese deposits in the State.

A carload of machinery for W. W. King, lessee of the Buckboard mine, 5 miles south of the Yellow Aster mine, has arrived at Johannesburg, and is being hauled to the mine. The Buckboard has been a producer in the past.

SHASTA COUNTY

(Special Correspondence.)—The electrolytic zinc-plant of the Mammoth Copper Co. has been completed and the production

of zinc will probably commence about May 15. Sections of the plant are being tested and the different departments synchronized. Visitors are not admitted to the works and the buildings are protected by a high barbed-wire fence, and the single gate is guarded both day and night. H. R. Hanley, inventor of the process, after seven years of experiments at the Bully Hill smelter, near Winthrop, will be in charge of operations. The plant is designed to extract zinc and other metals from the flue-dust arrested by the bag-house, and to recover metallic zinc from crude ore. Its construction represents an approximate expenditure of \$350,000.

The Accident group of quartz claims, six miles west of French Gulch, including the Sybil mine, has been sold to the Shasta Hills Mining Co. The deal unites conflicting interests, which will facilitate operations. It is stated that some good ore is exposed.

Lumber for the flotation-plant of the Afterthought Copper Co. is arriving at Ingot and construction of numerous mine-buildings is proceeding. Three auto-stage lines are operating between the camp and the railroad, and upward of 100 men are employed in and around the mine. The projected flotation-plant is to cost approximately \$100,000.

It is reported that the Balaklala Copper Co. will ship from its Coram mines to the Mason Valley smelter at Thompson, Nevada, as soon as the second furnace is blown in. At present 300 tons of ore is going daily to the Kennett smelter and recent work in new territory has been satisfactory.

Gus Bauer and associates, of Redding, are prospecting on the east side of the Sacramento river for oil, for which purpose \$5000 has been raised. Occasional pockets of natural-gas have been reported in this field in the past and several test-mills were drilled near here about 1900.

Kennett, April 30.

SISKIYOU COUNTY

(Special Correspondence.)—R. N. Burgess last week announced that plans for the building of a railroad from Grenada to Fort Jones had been approved and that construction of the line in the immediate future was assured. The railroad will be 60 miles long, and will traverse one of the richest mineral regions of the State. Branches are to be extended to Etna Mills and Scotts Bar. The districts through which it will pass contain numerous deposits of gold and copper, and a lack of transportation facilities has been the principal factor against extensive development and production.

The Siskiyou Syndicate has arranged for more vigorous work at its Cub Bear and Blue Jeans mines, above Etna Mills, and plans the building of a small experimental-plant at the Blue Jeans. Both mines have been under development for more than six years and much profitable ore is said to be blocked out. Seattle people are heavily interested.

Driving of a 600-ft. raise to connect the lower and upper adits has started at the Mt. Vernon gold mine, nine miles from Yreka. The orebody was intersected at a depth of 900 ft. by the main 600-ft. adit and it has been opened by drifts for 800 ft. The main vein is over three feet wide with free-milling ore. Stringers of rich ore accompany the vein. J. S. Dobyns is superintendent.

At a depth of 200 ft. in the Know Nothing mine a shoot of rich ore has been discovered. It ranges from one to three feet wide and shows much specimen quartz, assays running from \$50 to \$600 per ton. The mine was recently acquired by W. L. Beall, of Yreka, after having been abandoned for 16 years. Late work shows that the former owners missed the vein by two feet while sinking.

R. A. Lewis of Yreka has bonded his placer holdings to a company of Oregon and Idaho people, and the old Fairchild shaft will be sunk 50 ft. deeper to open the Blue Gravel channel, believed to course through the property. Orders have been placed for two large pumps.

Yreka, April 23.

TULARE COUNTY

(Special Correspondence.)—The Magnesite Refractories Co. of Porterville, has recently been reorganized and incorporated under the laws of Nevada. The new president is Ed DeMoulin, and E. W. Skinner is the secretary-treasurer. These, with W. H. Fuller, compose the new board of directors. H. L. Voss, formerly with the Porterville Magnesite Co. of this district, is local manager. The new corporation has opened an office in the Marsh-Strong building, Los Angeles. The original company had leased considerable foot-hill property, north of Porterville, from which magnesite is being mined. They are also buying custom ore in order to fill their Eastern contracts. As soon as the Visalia Electric railroad, which is constructing a line in that vicinity, builds a spur-track to the property, the company will erect a calcining-plant. The company has thousands of tons of magnesite on its dumps, and at other places upon its property. It is the intention also to bid on furnishing crushed-rock for the building of the system of highways throughout the county for which \$2,200,000 bonds were recently voted.

Porterville, April 26.

TUOLUMNE COUNTY

(Special Correspondence.)—A new body of ore has been discovered in a winze below the south drift on the 1800-ft. level of the Black Oak mine, at Soulsbyville. At the point of discovery the orebody was narrow, but in sinking it has widened rapidly. Recently a rumor gained circulation that the property was to suspend operations, owing to the increased cost of materials, but this has been emphatically denied. A company of local mining men are operating the Driesam mine, at Arastraville, under bond. Considerable development work has been decided upon.—The force at the Dutch mine near Jamestown was recently augmented to expedite the work of preparing for the extensive changes and improvements to be made in the plant.—An electric-hoist has been installed at the Yosemite mine and better progress is being made in sinking the shaft.—Extensive improvements are contemplated at the lime-plant of the Pacific Lime & Plaster Co., one-half mile south of Sonora. The capacity of the plant will likely be greatly increased.

Sonora, April 21.

COLORADO

CLEAR CREEK COUNTY

Pomeroy and Grenfell, lessees on the old Shively mine above Silver Plume, have the returns from their first shipment of ore this week. The ore ran 321 oz. silver per ton and 7% lead. This high-grade ore is in keeping with the past reputation of the mine, which was a large producer in the early '70s, and later, under the management of Warren Fletcher, who worked the property for several years successfully until the demonetization of silver. The property is owned by the Bank of Clear Creek County and has been idle for a number of years, and, although it was well known that it still contained bodies of high-grade ore, the price of silver up to last year would not permit of the mine being operated profitably.

The lessees took the property a little over a month ago and have had to do considerable dead work in cleaning out the levels.

This, their trial shipment, however, proves that their faith in the mine was well founded, and from now on a steady shipment may be looked for.

MISSOURI

JACKSON COUNTY

Lead production is the most important programme on the tract of the Lone Elm Development Co., of the Granby land, north-west of Joplin. Numerous companies are making good jack turn-ins, but the good price for lead has spurred many

operators to turn their attention to this ore exclusively, with the result that more lead is being produced from the property than for many years.

One of the most successful lead producers is Bell & Company. They are making approximately 20,000 lb. of galena and 15,000 lb. of drybone weekly, with a small equipment and a minimum expense.

Close to this tract the Alkali Ike company is sinking a new shaft with a prospect of finding the same run of lead being worked by Bell & Company, and on the other side Stevens, Roper & Company are sinking a shaft for the same purpose.

Hulett & Company are in a rich lead-bearing formation at a depth of 40 ft. and are getting both galena and drybone.

J. Van Skoyt has a lead prospect at a depth of 60 ft. and has started construction of a steam-rig.

Bailey & Company are producing regularly both lead and zinc at a depth of 90 feet.

The Lincoln Mining Co. is producing regularly from the old Van Skoyt diggings and is getting a good recovery.

Ball & Company and Enderline & Moser are each sinking new shafts on Lead Hill. Prewitt & Company are driving at 40 ft. in fine-looking lead ground. Dobbs & Daugherty are sinking a new shaft and are finding good shines and expect to get into the ore in a few days.

NEVADA

ESMERALDA COUNTY

During the month of March, the total production of the Goldfield Consolidated Mines Co. was 27,000 tons, from which resulted a net realization of \$19,727.89. During the month 1453 ft. of development work was performed at a cost of \$6.73 per foot.

The operating costs were as follows:

	Ore handled per ton	Total ore per ton
Mining:		
Stoping	2.641	
Development	23.519	
Total mining	3.086	2.483
Leasing expense	3.005	0.063
Dump-moving	0.410	0.069
Transportation	0.067	0.067
Milling	1.910	1.910
Marketing	0.040	0.040
General expense	0.357	0.357
Bullion-tax
Filter-royalty	0.027	0.027
Flotation-royalty	0.044	0.044
Surface	0.053	0.053
Total operating costs		5.113
Miscellaneous earnings		0.072
Net operating costs		5.041
Construction
Net costs		5.041

On the 130-ft. level of the Combination mine, 210 tons of \$20 ore was produced. In the Mohawk, on an intermediate level above the 350-ft. level, 116 tons of ore was mined in cutting the sill-floor. This ore assayed \$43.41 per ton. In the La Luna, on the 600-ft. level, 93 tons of \$153 ore was taken from a winze. During the month lessees produced 563 dry tons of ore having a gross value of \$9727.36 of which the company received \$5994.99, less cost of transportation and milling.

MINERAL COUNTY

(Special Correspondence.)—The mines of the Luning district are looking exceptionally well, according to John C. Skuse, who has operated there for some years. Mr. Skuse

speaks particularly well of the St. Patrick mine, recently acquired by the Kirchen Mines Corporation. Regular shipments are being maintained, and new buildings are being erected to house the larger crew that will be put to work as soon as they are finished. The winze that is being sunk from the 100-ft. level of the Nevada Champion is in splendid ore, the ore-shoot, which has been followed from the surface, has improved as depth has been gained. The Wall Street Turk mine is among the steady shippers and the management has recently inaugurated an elaborate system of development which is producing good results.

Luning, April 27.

(Special Correspondence.)—Sinking of the double-compartment shaft of the Queen Regent Merger mine has advanced to the 470-ft. point and is expected to cut the main orebody at any time. Sulphide ore has been showing from the 450-ft. workings. Sinking will continue to the 600-ft. level, from which point extensive lateral work will be undertaken. This is the mine that attracted much attention about a year ago by several shipments of specimen ore. The management claims the world's record for sinking a double-compartment shaft 400 ft. deep at a total cost, including timbering and development, of \$12 per foot.

The La Patt copper group, commonly known as the Copper Mountain, is being developed by the Jumbo Extension Co., of Goldfield. Twenty men are on the payroll and sinking of the No. 2 shaft is proceeding rapidly with good ore showing. Twenty-five lessees are also active and from the Miller-La Patt lease are shipping weekly three to four cars of ore assaying 10 to 17% copper, together with some gold and silver.

The Nevada Rand Co. has sunk the shaft on the Last Hope mine to a depth of 430 ft. and will cross-cut as soon as the 450-ft. level is established. This work is expected to intersect the vein which yielded rich ore near the surface.—About 35 teams and several motor-trucks are engaged in hauling ore and supplies between the Rand district and Nolan.

Rand, April 28.

NYE COUNTY

(Special Correspondence.)—The Louisiana Consolidated Mining Co. is sorting the dump at the main-shaft of the Tybo mine and soon will have a carload ready for shipment that will run better than \$175 per ton. This dump, which contains 4000 tons, came from a drift on the vein at the 400-ft. level. The best of the ore was shipped at the time it was mined but it is believed that the entire 4000 tons left will average \$50 per ton. Grab-samples of the finer stuff shows that it will run \$35.76 per ton, while a second-class dump is being piled up in addition to the high-grade mentioned. The 400-ft. is the lowest level that has been opened in the Tybo mine and the average values were 64% higher than on the 300-ft. level and above. It is the intention of the Louisiana company to start sinking as soon as the mine is unwatered, which will probably be along the last of May.

Eureka, April 20.

(Special Correspondence.)—The White Caps Co. has arranged to sink the shaft 125 ft. deeper, which will give an approximate vertical working-depth of 600 ft. Work on the fourth level has established the junction of the West and Shaft veins. The West vein on this level has been proved for a length of 70 ft. and has an average width of 15 ft. Its limits at this point have been established. The roaster is being installed in the mill. Building of a road to connect the mine with the Manhattan-Tonopah highway will start in a few days.

At the Morning Glory an electric-hoist is in position and sinking has begun. Hand-drills are being used but an order has been placed for a four-drill Ingersoll-Rand compressor. The management expects to reach the orebody within 50 ft. Meanwhile, a segment of the Consolidated vein-system is being developed near the surface.

Sinking at the Manhattan Consolidated has reached a depth of 295 ft. with the bottom in crushed shale carrying quartz stringers. Expecting that a heavy flow of water may be struck near the orebody, a No. 6 Cameron pump is being installed.

East and west drifts are advancing from the 600-ft. level of the Union Amalgamated. The east drift is expected to intersect the Earl vein-system about 300 ft. distant. The east drift has cut an ore-shoot 3 ft. wide, assaying \$16 per ton.

The Thelma, White Caps Extension, and Cash Entry groups have been merged into a company controlled by John G. Kirchen, Jesse Knight of Salt Lake, and other Nevada and Utah people. The territory lies near the White Caps mine and will be developed under supervision of John G. Kirchen.

Manhattan, April 28.

STOREY COUNTY

The new development on the 2700-ft. level of the Mexican mine continues to look well. Recently five cars sampled over \$99, and four cars ran \$132 per ton. On the 2700-ft. level of the Consolidated Virginia ore is being stoped across a width of 10 ft., the average value being \$14 per ton. There are new and promising developments in the Sierra Nevada mine. Years ago some good ore was found there near the Union line, but it was not developed. Recently a drift was run to reach the ore and the rock broken begins to look well.

NEW MEXICO

GRANT COUNTY

The 85 Extension Copper Co., has taken over the Atwood mine at Lordsburg, and is preparing for continuous production. The recently installed electric-pumps will have unwatered the workings by the middle of the coming week.

LUNA COUNTY

(Special Correspondence.)—The Empire Smelting & Refining Co. will operate a lead-smelter at Deming. The furnace will be blown-in May 1. A concentrating-plant also is being installed for the treatment of ores of vanadium and molybdenum.

Deming, April 26.

SANTA FE COUNTY

A sale was recently made by John O. Jones of the Anna Jones group of mining claims, also the sale by T. Z. Winter of the adjoining group. The entire eastern part of Santa Fe county, north of the line of the Atchison, Topeka & Santa Fe railroad, is known to be rich in copper, gold, and silver, while it is also known that some of the rarer metals exist more or less abundantly. The majority of the known properties are located on or near a contact between the granite and lime which traverses the county in a north-east direction. The Anna Jones group is situated on the high mountain ridge between Indian creek and the north fork of the Macho.

SOCORRO COUNTY

(Special Correspondence.)—Louis Gramas has opened a 3-ft. breast of mill-ore in a lower tunnel on his Gold Eagle group and is preparing to make a shipment to custom works.

The Socorro Mining & Milling Co. produced 18 bars of gold-silver bullion during the first half of April. The bullion product of the Mogollon Mines Co. for the same period was 15 bars.

The Oaks Company has developed a good back of ore above the adit on the Maud S mine. Ore-bins have been completed, track laid, and ore-chutes placed in readiness for economical handling of ore. The trail to the Socorro mill is finished and it is planned to begin extensive production at once.

After years of effort this district is to have a new outlet by way of the lately created State-road across the divide from Mogollon to Magdalena. Funds for the construction are available from both the Forest Service and the State treasury, and it is understood that work is to start at once. In addition to

facilitating various lines of business this road has unusual scenic features, traversing a wide area, most of which is in its original state.

Mogollon, April 24.

OKLAHOMA

CRAIG COUNTY

Seventeen armed under-sheriffs are employed by the Commerce Mining & Royalty Co. in guarding its properties in the Oklahoma field. Some other companies have guards and more will put them on, according to recent reports. Safeguarding the plants is considered not only necessary for personal property protection but as a national duty.

In the Wisconsin zinc district members of the State militia have been stationed at different points, since there have occurred explosions at the powder houses of two different company storehouses. It is stated that there was no evidence to show that the explosions were other than accidental, but mine-owners have asked for protection for their properties and have been granted it.

Protection of the powder-making industry, so closely allied with mining in this field, is being thoroughly worked out. At the plant near Columbus, Kansas, H. F. Donnelly, superintendent, recently gave out an interview refuting a rumor that guards employed at the plant are not armed.

"The guards are armed and have orders to fire after a single command to halt is disobeyed," says Donnelly, who also explains that the guards have regular trips to make about the plant and along the company's railroad track. Clocks have been distributed at different points along the beats and watchmen must register on schedule. If any guard is more than ten minutes late in reporting, other guards start out to investigate the cause of the trouble.

Due to decreased demand from the mines, the plant shut down April 1, and will not be in operation again until May 1, the time being used to make needed repairs.

OREGON

JACKSON COUNTY

(Special Correspondence.)—In the spring of 1916, John McRunnels and Dick Swacker, miners of Gold Hill, while tracing for the source of fine gold in the soil, uncovered a promising vein, six miles south-west of Gold Hill, and west of Rogue river. It is within a mile of the river, and about 300 ft. above the bed of the stream. The discoverers uncovered the vein, and within a few feet of the surface, found a pay-shoot, which extended for 150 ft., with a depth of from 10 to 35 ft. They recovered about \$1000 in gold from this shoot; the vein was from 3 to 12 in. wide. It strikes south 80° west and dips 20° north. The hanging wall is porphyry, and the foot-wall diorite; the vein is composed of crystal and decomposed quartz, and is free-milling. The discoverers refused several offers, and later were unable to agree as to the manner of developing the prospect. Recently McRunnels sold his interest in the property to John T. Donegan, a local miner. The present owner is preparing to sink a shaft on the vein to demonstrate the worth of the property.

Gold Hill, April 28.

UTAH

BEAVER COUNTY

(Special Correspondence.)—The Utah Leasing Co. is operating a 500-ton flotation-plant, treating tailing from the old South Utah Mines & Smelters concentrator. An additional 8-ft. by 30-in. Hardinge ball-mill is being put in and will be ready about April 25. In connection with this a 20 by 20-ft. and a 10 by 50-ft. Dorr thickener, for thickening concentrate, are being erected. At this plant 30 men are regularly employed.

Newhouse, April 18.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

MALCOLM MACLAREN is in Peru.

H. R. NORSWORTHY has gone to Plumas county, California.

RICHARD A. PARKER was at Breckenridge, Colorado, last week.

BENJAMIN REZAS is visiting mines in Shasta county, California.

KENT E. KELLER, of Ava, Illinois, formerly in Mexico, is visiting California.

FRANK A. BIRD is manager for the firm of R. H. Officer & Co. at Salt Lake City.

H. C. HOOVER has been elected an honorary member of the Canadian Mining Institute.

J. G. DICKENSON and P. McDONALD have returned to Cobalt, Ontario, from Prescott, Arizona.

E. C. BAUER is now assistant to the vice-president of the American Manganese-Steel Co. of Chicago.

R. S. Baverstock has been in Silver Peak district, and has now gone to Lida and Hornsilver, Nevada.

THOMAS M. BAINS, JR., has resigned as Instructor in Mining in the Case Institute and is now at Berkeley.

E. C. KLINKER has returned from Honolulu to the Columbia Consolidated Mines, at Washington, California.

BRENT NEVILLE RICKARD has been transferred from the Murray plant of the American Smelting & Refining Co. to the Tacoma plant.

HENRY M. HOWE has been awarded the John Fritz medal and will receive it at a presentation ceremony to take place at the United Engineering building, New York, on May 10.

F. N. FLYNN, general superintendent of the Chile Exploration Company, at Chuquicamata, Chile, has severed his connection with that company and is due to arrive at New York.

C. R. RICHARDS, professor of mechanical engineering, has been appointed dean of the College of Engineering and director of experiment station of the University of Illinois, in succession to Dr. W. F. M. Goss, who has resigned to become president of the Railway Car Manufacturers Association of New York.

The Peruvian government has granted a concession for explorations for gold and ore in the rivers of Marcapata, Nushiscato, Huayllumbe, and Crayumayo. The concessionaire, Juan C. Diaz, will begin explorations in the beds and banks of these rivers and their affluents within six months, and terminate the work within two years. El Peruano gives the terms of the concession, stating the privilege of the concessionaire to work certain of the auriferous deposits, with the payment of 10% of the net profits from such mines to the

STEEL AND COPPER will win the War for the United States, says the Boston News Bureau. The United States has a capacity for turning out from 45,000,000 to 50,000,000 tons of steel ingots per year. Great Britain, France, and Russia have a capacity of about 20,000,000 tons. Germany's capacity, under war conditions, is not much over 17,000,000 tons. The United States and Allies have a combined capacity of over 65,000,000 tons, not including Japan, or nearly four times the steel capacity of Germany. Nearly all the copper that is being produced in the world today is being refined in this country. Steel and copper will win the War.

THE METAL MARKET

METAL PRICES

San Francisco, May 1

Antimony, cents per pound	23
Electrolytic copper, cents per pound	37
Pig lead, cents per pound	9.25—10.25
Platinum, soft and hard metal, per ounce	\$105—111
Quicksilver, per flask of 75 lb.	\$110—111
Spelter, cents per pound	12
Tin, cents per pound	55
Zinc dust, cents per pound	20

ORE PRICES

San Francisco, May 1

Antimony, 50% metal, per unit	\$1.80
Chrome, 40% and over, f.o.b. cars California, cents per unit	50—55
Magnetite, crude, per ton	\$8.00—12.00
Tungsten, 60% WO ₃ , per unit	18.00—20.00
Molybdenite, per unit for MoS ₂ contained	40.00
Manganese, 45% (under 35% metal not desired), cents, unit	36—38

Buyers of manganese ore transact business on a basis of the long ton of 2240 lb., for which the present price is \$19 per ton for 45% ore. For each additional per cent 65c. is paid above the base rate, and the same deduction, of 65c., is made for each unit below 45%. Thus for an ore running 48% MnO₂ the present price is \$19 + \$1.95 = \$20.95, and an ore containing 42% MnO₂ is worth \$19 — \$1.95 = \$17.50. Ore running under 35% MnO₂ is not wanted. A silica content up to 8% is permissible. A penalty of 50c. per unit is taxed on silica over 8%, up to 15%. If containing more than 15% the ore is not marketable.

EASTERN METAL MARKET

(By wire from New York)

May 1.—Copper is firmer, from 30.25 to 31c. Lead is stronger at 9.50 to 9.75c. Spelter is more active at 9.25 to 9.50 cents. Platinum remains unchanged at \$105 to \$111.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date	Average week ending

May	49.87	74.27	72.51
June	49.03	65.04	75.70

Public interest has been aroused by the recent changes in the price of silver, and with the interest displayed the question arises as to the extent of the world production of the metal.

Within the last two years there has been a phenomenal rise in the price of silver, a rise which started from an extremely low level—for the lowest quotation of 1915 of 45.6c. an ounce was only 1.7c. above the very lowest quotation (in 1902 and 1903) ever recorded on the silver market. At the outbreak of the War silver slumped from 56c. an ounce to 45c., and remained between 44 and 46c. up to February 1915. Late in 1915 an advance commenced and continued until 75c. was reached in May 1916. There was a sharp reaction to 58c. in July, but by the end of the year 75c. was again reached. The market remained firm, and quite recently the price hardened to about 77c., a higher quotation than in any year since 1893.

The world's production of silver in 1916 was 177,400,000 fine ounces, of which the United States contributed 72,900,000 ounces.

The six largest disseminated-copper mines of the United States during 1916 produced 600,000,000 lb. of copper, which is about 25% of the entire production of the country. The average cost of this copper was 8.6c. per lb. The net profits of the six companies operating these great mines was \$108,730,000, from which dividends to the amount of \$51,000,000 were paid. To accomplish this 24,000,000 tons of ore was mined and treated. By far the greater part was mined in open-pits by means of steam-shovels, the ore being concentrated and the concentrate shipped to smelters for reduction.

The companies above referred to and the amounts of copper produced by each, the cost of production, the amount of ore still held in reserve, and the average estimated copper content is shown in the following table:

	Copper, lb.	Cost per lb., cents	Ore reserves, tons	Av. copper content, %

Miami	53,518,331	9.520	50,400,000	1.82
Total	599,861,127	8.600	768,956,864	1.60

These great mines doubtless will be called upon heavily to supply copper to the Government during the term of the War, but no one doubts their ability to comply with the heaviest demand that may be made upon their resources, which, as indicated above, approximates a billion and a half tons of ore, containing on an average about 1.5% copper, or about 22,500,000 tons of metal.

Eastern Metal Market

New York, April 25.

The metals are divided into two camps—the strong and the weak. Two of the leading ones are weak and two are strong. Because of light transactions in some, the quotations are nominal, but the entire situation is uncertain, dominated by war conditions in our own country, and by lack of definiteness as to just how much metal the Government will buy.

Copper is nominal and lower on offerings of small lots.

Zinc continues weak and declines almost daily.

Lead is strong and firm, with sellers holding aloof.

Tin is higher, with a fair business reported.

Antimony is dull and a little lower.

In the steel market the amount that the Government will want the first year exceeds the first estimates. It is now put at 1,000,000 tons of plates, shapes, and bars. Already Government business taken at Pittsburg amounts to 100,000 tons of plates. The indications are not favorable to the extension to the Allies for their last half needs of the low prices granted the U. S. Government on steel and copper. The feature of the week was the statement of the U. S. Steel Corporation for the first quarter this year, showing net earnings of over \$113,000,000 and an extra dividend of 3% on common stock, making it 4½% for the quarter. Rail buying into 1919 has developed, and price advances on finished steel continue to appear.

COPPER

With the market still declining on offerings of small lots, and with almost no business transacted, there is not much that can be said. There is absolutely no interest on the part of buyers for any position. While it is manifestly a buyers' market, the buyers will not nibble, offerings of metal at 25c., New York, for far future delivery causing no enthusiasm. Large and small purchasers are merely looking on and waiting to learn the actual needs of the Government and the Allies. All kinds of speculation as to these requirements is heard, both as to quantity and particularly as to price, but nothing definite is known. Producers are well sold up to July 1, nearby metal being obtainable only in small quantities as re-sale lots. The March exports, just made public, were large—45,327 gross tons, against 32,265 tons in February this year; 26,231 tons in March, 1916, and 30,148 tons in March, 1915. The London market is still declining, yesterday's quotation for spot electrolytic having been £142, a decline of £5 from that of last week, and £9 per ton from that of two weeks ago.

LEAD

The metal is strong and active so far as inquiries are concerned, but the inclination of sellers is to hold back. The absorbing topic is the probable needs of the Government. These are not definitely known, but rumors based on fairly definite information place them at figures which will surprise the trade when made public. The army's needs will more than double those of the navy, and the total will exceed the largest estimates. The entire week has been characterized by a strong undertone, with the demand greater than the supply. Spot lead is scarce. Sales the last of last week were fairly good under the conditions. The quotation yesterday was 9.30c., St. Louis, or 9.50c., New York, for spot and April metal, with higher prices probable in the near future. The American Smelting & Refining Co.'s price is still 9c., New York. The London quotation yesterday was £30 10s. for spot metal.

TIN

There have been no more developments regarding the proposed Government tax of 10% on tin imports and the trade continues to believe more firmly that this will not be imposed.

The week has been generally dull, but the tone strong, especially yesterday and Monday. On April 18 the market was quiet, with sales of about 150 tons reported, mostly futures, with few sellers concerned. On April 19, in a dull market, about 100 tons of nearby tin went to one concern. Spot Banca tin was sold on April 20 at 54.50 to 54.75c. with most of the day very dull but more active inquiries appearing toward the close. On Monday the announcement of an increase of 2% in the war insurance-rate, making it 5%, caused a sharp advance, spot Straits selling on that day and on Tuesday at 57.50c., due to this increased rate. The explanation offered is that there have been probable sinkings of tin-laden ships, known in London, because the price advanced there £5 per ton on Monday, which is more than the 2% rise in insurance. The tin afloat at the close of business, April 24, was 2812 tons, with the arrivals at 2040 tons. The London market has advanced sharply to £24 12s.6d. yesterday for spot Straits, an increase of about £7 over last week.

ZINC

In the continued absence of any life or demand the only interesting feature of the past week has been the publication of the U. S. Geological Survey's report of the 1916 output of primary spelter, showing over 667,000 net tons produced or a gain of 37% over the large production of 1915. One prominent dealer points out that if, to the apparent consumption shown by the report, there is added the exports, the total is only 3000 tons short of the output. It is believed that strikes and other causes lately have curtailed the present output. While the market is at present 'sick,' competition for the little business offered forcing prices down, it is regarded as certain by some that a turn will come not long after the Government's requirements are made known. The quotation today for prime Western for nearby and April shipment is 9c., St. Louis, or 9.25c., New York, though probably desirable business would bring out a quotation ¼c. lower.

ANTIMONY

Demand for spot metal has quieted down. It can now be obtained for 34 to 34.50c., New York, but the amount available is not believed to be large, and it will be some time before any more may be expected by vessel.

ALUMINUM

The quotation is 58 to 61c. for No. 1 virgin metal, 98 to 99% pure, depending on the quantity and delivery wanted.

ORES

ANTIMONY. For April nearby shipment the quotation is \$2.25 per unit, with the market very quiet.

MANGANESE. The difficulties in obtaining regular shipments from abroad are increasing almost daily, and manufacturers here who have relied upon Indian and South American ore are now trying to secure such manganese ore as is produced in this country, Cuba, or Central America in general. Such small lots as actually reach our market have found ready buyers and 85c. was paid on the basis of 45% material.

MOLYBDENUM. The quotation ranges from \$2 to \$2.25 per lb. of molybdenum contained, but the demand is light and the transactions reported are small.

TUNGSTEN. Sales of fair quantities of concentrate continue to be made at \$17 to \$18 per unit. Inquiries are reported as heavy during the past week, and higher prices are not unlooked for. Arrivals from South America have not been large because of the scarcity of bottoms. Both domestic and foreign inquiries for ferro-tungsten continue to appear, the quotation for which is from \$1.90 to \$2.10 per lb. of contained tungsten.

The Bunker Hill & Sullivan Change-House

The Bunker Hill & Sullivan Mining & Concentrating Co. at Kellogg, Idaho, gives much attention to the care of its workmen. A convenient and properly designed change-house is a necessity at every mine, and this the company has provided. The accompanying illustration is an interior view of the upper floor of the change-house, showing some of the clothes-hangers lowered for the removal of clothing, and others hoisted beside the steam-coils for drying. Shower-baths are provided in the individual compartments at the left side of the room. There are also tubs with hot and cold water for washing clothes. Other appointments have been provided to insure sanitary conditions, and with a view to the convenience of the men.

THE BUNKER HILL & SULLIVAN CHANGE-HOUSE, KELLOGG, IDAHO

Mining companies generally are realizing more and more the importance of the proper care of their workmen, and well-appointed change-houses are becoming general.

Rescue Work in Burning Mines

In these days of an ever increasing interest in the health and general welfare of employees, much thought has been given to methods of rescuing men from burning mines, and from parts of mines where deadly gases have accumulated from natural or other causes. Seldom has the utility of the modern rescue-apparatus had a better test of its great value and efficiency than was afforded recently in one of the leading Butte mines. Years ago the heavy mass of sulphide ore in the

Leonard mine took fire—how is not positively known, nor is it important, in this connection, but it is of importance that, notwithstanding every effort that has been made to extinguish the fire it still burns, sometimes smouldering slowly and at others with surprising vigor. Sulphurous gas, smoke, and carbon di-oxide at times fill some of the workings and the men not infrequently have narrow escapes from asphyxiation. Not long since, the gas broke into workings where numerous men were employed. Some were on the levels and had a fair chance of escape, but others were up in stopes, and were practically cut off from a quick and easy passage to safety. Heroically the stronger men endeavored to aid the weaker ones, who otherwise must have perished, but in most cases the former were compelled to run to save their own lives, if possible. Rescue apparatus was at hand and one experienced man entered the

gas-filled workings and dragged two or three men from perilous positions to places of safety. Other men, who had never worn the apparatus, then volunteered their services. Equipped in helmets and armed with the necessary implements, they descended the shaft with the leader, and by their aid the imperilled men were taken out, some of them more dead than alive, but by the administration of restoratives and application of the various means employed in resuscitating men in such condition, all were saved. The accompanying illustration shows one of the Bureau of Mines rescue cars which is fully equipped and is to be taken from place to place for the purpose of giving instruction to the miners that they may be able promptly to act in just such emergencies as the one above described. How quickly these men may become efficient is shown by the incident above related.

U. S. BUREAU OF MINES RESCUE-MACHINE

Company Reports

ALASKA JUNEAU GOLD MINING CO.

The second annual report of the Alaska Juneau Gold Mining Co., for the year ended December 31, 1916, is as follows:

During the year the greater part of the underground work has been confined to the completion of the plans to prepare the mine for the production of 8000 tons of ore daily. It was decided to start the development work necessary to mine 2000 tons daily from the surface by the open-pit method, in that part of the property lying between the Silver-Bow fault and the East property line. Also to prepare the North orebody for mining operations farther north-west along the strike than had been contemplated in last year's report. The total development done in connection with the general program as outlined was: drifts and cross-cuts, 8958 ft.; raises, 7457 ft.; intermediate drifts, 1986 ft.; powder-drifts, 2645 ft.; stations, 1531 ft. Total, 22,577 ft. As none of the underground work was of an exploratory character, there is nothing to report regarding changes in the general appearance of the mine. The average assay value of all development-work samples taken from the orebodies to December 31, 1916, show for the North orebody 2680 samples, average assay value, \$0.802. South orebody, 776 samples, average value, \$0.94. For the entire mine, from all levels, 3456 samples returned an average value of \$0.832.

Ore was sent to the mill from development work as follows:

	Tons
No. 2 South	2,838
No. 2 North	7,466
No. 3 North	16,119
No. 4 North	20,649
Total	47,072

From No. 4 North 133,041 tons was sent to the mill from the stopes, making a total of 180,113 tons.

The 50-stamp pilot-mill operated continuously throughout the year, but under somewhat restricted capacity during the last few months, during which time there was considerable obstruction to ore tramping on account of the work in connection with double tracking the railroad and the substitution of 50-lb. rails with 40-lb. rails. No work deserving special mention was undertaken in the mill during the year, but a number of problems have been worked out and the knowledge thereby gained has been incorporated in the flow-sheet of the new mill. While the final tailing assays are normal the losses during the year have been abnormal, due to the fact that a large quantity of coarse sand, averaging \$0.322 per ton or \$0.0328 per ton milled, has been used in connection with the concrete work in the new mill.

INSPIRATION CONSOLIDATED COPPER COMPANY

The annual report of the Inspiration Consolidated Copper Co. for the year ended December 31, 1916, shows the following: Ore reserves, at the end of the year 1915, 97,143,000 tons; mined during the year 1916, 5,353,880 tons. Reserves at the end of 1916, 91,789,120 tons. Of this reserve, 20,000,000 tons is classed as oxide ore. During the year experimental work was carried on to devise a satisfactory method of treating the oxidized ore, and good results were obtained. A suitable small plant is being built to continue these investigations. The last unit to the mill was completed February 21, 1916, since which time the entire plant was in continuous operation. Practically 91% was saved on an average ore assaying 1.548% copper. Two additional sections of the mill soon will be in operation, which will insure a daily capacity of 16,000 tons. The mine can easily maintain a production of 20,000 tons daily. The yield of re-

fined copper was 22.625 lb. per ton of ore; and the cost of copper, exclusive of depreciation, was 8.673c. per pound. The net profit for the year was \$20,629,489.30. Out of the net earnings of the year four dividends, aggregating \$7.25 per share were declared, being a total of \$8,548,050.75. The total mine openings at the end of the year was 60.76 miles. The cost of mining per ton of ore was \$0.607; of coarse-crushing \$0.02798; of ore haulage, \$0.0154; of concentrating and royalties, \$0.5038; of concentrate hauling, \$0.00145. Total, \$1.15576. Smelting, freight, refining, and marketing, \$0.79269. Total cost of mining, milling, and treatment, \$1.94845. Tonnage treated during the year, 5,316,350 tons; copper produced, 119,431,389 pounds.

CERRO GORDO MINES CO.

The first annual report of the Cerro Gordo Mines Co. includes the interval from October 1, 1915, to December 31, 1916, and is as follows:

CASH RECEIPTS

From sale of silver-lead, zinc, and copper ores.....	\$310,764.61
From sale of slag	40,382.94
From sale of 100,000 shares stock at \$1.....	100,000.00
From sundry sources	8,641.96
	\$459,789.51

CASH DISBURSEMENTS

Expenditures for improvements since date of acquisition	\$146,056.75
Labor and supplies	175,717.68
Miscellaneous	1,263.07
Dividend No. 1.....	24,375.00
	\$347,412.50
Cash on hand and in bank Dec. 31, 1916	\$112,377.01

ZINC-ORE PRODUCTION

Last quarter of 1915, 2039.072 tons, containing 1,243,584 lb. of zinc. During the year 1916, 11,264.719 tons, containing 6,968,869 lb. of zinc. The average content of zinc in this ore was 30.93%.

LEAD-ORE PRODUCTION

During 1916 only 1496.831 tons of ore was produced of the following value:

Gold, oz.	Silver, oz.	Lead, lb.	Lead, %	Lead, lb. per ton
20.245	32,246	1,053,426	35.188	703.77

SLAG PRODUCTION

Tons	Silver, oz.	Lead, lb.	Lead, %	Lead, lb. per ton
9431	27,594	2,200,170	11.67	233.291

COPPER-ORE PRODUCTION

Copper ore was produced only during the month of December, 1916, to the amount of 26.675 tons, containing 453 oz. of silver, and 2238 lb. of copper.

CHINO COPPER COMPANY

The annual report of the Chino Copper Co. for the year ended December 31, 1916, shows the following: The gross production in concentrate and direct shipments of ore was 75,761,978 lb. Smelter deductions made the net production 72,319,508 lb. The gold and silver production realized from the smelter was \$80,498.22. The amount of ore handled was 3,094,400 tons. The net cost of producing copper was 8.706c. per lb. after deducting miscellaneous earnings for the year from the cost of producing copper. This deduction amounted to 0.45c. per lb. The net operating profit was \$12,517,876.18. Miscellaneous income, dividends, rentals, etc., amounted to \$325,285.55, making a total net profit of \$12,843,161.73, or \$14.76 per share. Dividends paid during the year aggregated \$8.25 per share, being a total of \$7,177,335. A re-calculation of ore reserves at the end

of 1916 was 95,555,843 tons, containing an average of 1.656% copper. Of this quantity 94,490,936 tons averaging 1.655% copper remained unmined. The remainder, amounting to 1,064,907 tons, consists of mixed sulphide and carbonate ore stored in stock-piles, and contains an average of 1.81% copper. The total amount of ore and waste removed by steam-shovels during the year was 5,300,891 cu. yd. of which 3,216,065 tons was ore. Of this ore 646 tons was shipped direct to the smelter. The average cost of steam-shovel operations in removing ore and stripping waste was 37.97c. per ton. The cost of mining ore was 19.88c. per ton, an increase of 2.1% over the previous year, due principally to increased cost of labor and supplies.

CALUMET & HECLA MINING COMPANY

The annual report of the Calumet & Hecla Mining Co. for the year ended December 31, 1916, shows the mine to have had one of the most satisfactory of its many years of activity. During the year 3,166,274 tons of rock was treated at a mining cost of \$2.03 per ton. From this was produced 71,349,591 lb. of copper, the average content being 22.53 lb. of copper per ton of ore. The total cost of production of copper was 11.63c. per lb. and the average price received for the metal was 25.48 cents. The price varied from 22.5 to 35.5c. per lb. Four dividends were paid during the year: \$15 per share on March 23, \$15 on June 24, \$20 on September 22, and \$25 on December 20.

During the year the necessary connections were made between the Calumet & Hecla and the Tamarack-Osceola systems. It has been decided to add 10,000 kw. to the power equipment, which will then have a total of 22,500 kw. All of the stamps ran throughout the year, practically without interruption.

The leaching-plant was put in operation in July and the result was so satisfactory that it has been decided to enlarge this branch of the equipment to a total capacity of 4000 tons daily. The reclamation-plant ran continuously in spite of the severe winter. With a temperature below zero for the greater part of 10 weeks and with 18 in. of ice on Torch lake, the dredge was kept going without loss of time. This plant treated 727,459 tons of tailing, producing 6,995,451 lb. of copper, the cost of which, exclusive of smelting and selling charges, was 4.39 cents.

MIAMI COPPER COMPANY

The annual report of the Miami Copper Co. for the year ended December 31, 1916, showed the following:

The net production of copper during the year was 53,518,331 lb. from the treatment of 1,842,017 tons of ore. The recovery in the concentrator was 73.88% of the total copper in the ore, of which 95% was returned in merchantable form, the difference being accounted for in smelting and refining losses. Improvements have been made in the concentrator that will augment the saving. Churn-drilling and underground work increased the ore reserves so that on January 1, 1917, the reserves were estimated as follows:

Sulphide ore, 2.4% copper, 16,400,000 tons; sulphide ore, 1.06% copper, 28,000,000 tons; mixed sulphide and oxide ore, 2%, 6,000,000 tons.

In order to put the property on a 6000-ton a day basis with a high concentrator recovery, additional power will be required and the power-house will be enlarged by the installation of two 610-hp. boilers and two 4000-kw. turbo-generators.

The cost per ton was \$1.937, divided as follows: Mining, \$1.1188; milling, \$0.5891; general expense, \$0.2294.

RAY CONSOLIDATED COPPER COMPANY

The annual report of the Ray Consolidated Copper Co. for the year ended December 31, 1916, shows the following: A recalculation of ore reserves in the property gives an estimate of 93,373,226 tons, containing an average of 2.03% copper. The net copper production for the year was 74,983,540 lb. The cost

of production was 10.267c. per lb. of copper, this high cost being largely due to increase in the wages paid, this being based on a sliding-scale. The net profit for the year available for dividends amounted to \$12,084,165.77, or \$7.66 per share. Of this amount \$4,337,954.75—\$2.75 per share—was distributed in dividends. The total amount of ore mined from all sources, and shipped to the reduction works at Hayden was 3,363,466 tons, an average of 9190 tons per day, containing 1.63% copper. The mining cost was 80.073c. per ton, of which 5.146c. per ton was due to coarse-crushing and loading, leaving the net mining cost 74.927c. per ton.

PORTLAND GOLD MINING COMPANY

The 23rd annual report of the Portland Gold Mining Co. of Cripple Creek, Colorado, for the year 1916 is as follows:

Gross value of ore mined and shipped.....	\$2,236,842.46
Gross value recovered by mills at Victor.....	612,576.89
	<hr/>
	\$2,849,419.35
Net cost of mining and milling.....	2,102,715.92

Gross profit	\$746,703.43
Revenue from other sources	22,106.41

Total net profit	\$768,809.84
------------------------	--------------

During the year there were mined and shipped or treated at the Victor mills, 96,045.513 tons of ore. Sinking, driving, cross-cutting, and raising totaled 18,263 ft. The total work done in the property to date is 310,850 ft. The total for the Portland mine is 58 miles, 4610 ft.; for the Independence mine, 16 miles, 1111 feet.

ALLOUEZ MINING COMPANY

The annual report of the Allouez Mining Co. for the year ended December 31, 1916, is as follows: Copper produced, 10,219,290 lb., sold at an average price of 25.305c., realizing \$2,586,011.13. Silver sales, and miscellaneous receipts, \$47,668.20, making a total of \$2,633,679.33. Running expenses at the mine were \$901,041.83. Expended on construction account, \$22,321.35. Freight, smelting, commission, and Eastern office, \$185,805.37. Total expense, \$1,109,168.55, leaving a net operating profit of \$1,524,510.78. Four dividends were declared during the year, aggregating \$900,000. During the year 566,960 tons of rock was treated, at a cost of \$1.589 per ton, including mining, transportation, stamping, and taxes.

LA SALLE COPPER COMPANY

The annual report of the La Salle Copper Co. for the year ended December 31, 1916, shows the following: Copper produced, 1,380,352 lb., which was sold at 25.68c. per lb., returning \$354,409.23. Sales of silver amounted to \$13,843.80, making total receipts from operation, of \$368,253.03. Running expenses of the mine were \$259,540.47. Construction cost \$163.86. Smelting, freight, commission, and Eastern office expense was \$29,306.82. Balance of interest charge, \$386.79, making a total expense of \$289,397.94. There was treated 144,829 tons of rock. Cost of mining, transportation, stamping, and taxes was \$1.79 per ton of rock.

SUPERIOR COPPER COMPANY

The annual report of the Superior Copper Co. for the year ended December 31, 1916, gives the following: Rock treated, 185,315 tons; copper produced, 3,034,656 lb., which was sold at 24.67c. per lb., for \$748,732.40. Sales of silver and interest, \$26,732.72. Total receipts, \$775,465.12. Running expenses at the mine, \$382,982.16. Smelting, freight, commission, and Eastern office, \$60,549.89. Total expense, \$443,532.05, leaving a net balance of profit of \$331,933.07. A dividend, No. 1, of \$1 per share was paid October 10, amounting to \$100,000.

Mining Decisions

MINING CLAIM—RIGHTS-OF-WAY OVER

Where the locator of a mining claim conveys all his right, title, and interest in a strip thereof to a railroad company, over which the line of road is constructed, the area so conveyed should be excluded from application for patent for the claim.

Frank Eyraud (Land Department), 45 Land Decisions, 212. July 10, 1916.

PLACER LOCATION—LEGAL SUBDIVISIONS

The smallest legal subdivisions authorized by statute in which placer claims on survey lands may be located and described are ten-acre tracts, normally in square form; but where location of a claim by ten-acre tracts in square form would necessitate the inclusion of lands which have passed out of the public domain or which are embraced in adjoining mining claims, the claim may be located and described by rectangular ten-acre tracts, even though not in square form.

William J. Harris (Land Department), 45 Land Decisions, 174. May 31, 1916.

ADVERSE CLAIM—EFFECT OF SUIT

A senior applicant for a mineral patent does not by the filing of an adverse claim against a conflicting junior application, and the institution of suit thereon, abandon or forfeit any rights under his senior application; and the pendency of such adverse suit does not operate as a stay of proceedings in the Land Department on the junior application pending determination of the suit.

International Asbestos Mills & Power Co. et al. (Land Department), 45 Land Decisions, 158. May 25, 1916.

EXTRA-LATERAL RIGHTS—"LODE" AND APEX DEFINED

A finding by the Court that "lenses or ore-shoots * * * have an easterly and westerly course reaching to or near the surface within the Granite lode and * * * come to the surface near the 4400 contour in a course slightly north of east to a stope which comes to the surface near elevation 4475," and again that the "orebody or ore-shoot which follows the bedding-planes, extends easterly and is disclosed on the surface at top of raise at elevation 4487" and that is again disclosed "at the top of raise 4587," amounts to a finding of an apex within the surface boundaries of the Granite claim. The orebody was found to have a definite "strike" and "dip," although it terminated on the strike against a wall of monzonite within the claim, and the dip was less than 45 degrees.

A lode containing lenses or lenticular bodies of ore or ore-shoots embodied in tilted beds of sedimentary strata might be classed by a geologist as a "bed" and not a "lode," but the law does not make distinctions based upon genetic principles. "A vein or lode comes within the meaning of the law so long as there is a fissure, seam, or gouge or any evidence of mineralization which will lead the practical miner from one orebody to another and which does in the course of his work so lead him."

The course of a vein where it is a crooked one is not determined by its direction at a single point, but by the course of the entire apex. The fact that it twists on its downward course into different courses does not affect this principle. The boundaries of the extra-lateral rights will be determined by the course of the apex, even though that course be nearly vertical at the point where the vein terminates against the monzonite wall.

Alameda Mining Co. v. Success Mining Co. (Idaho), 161 Pacific, 862. December 29, 1916.

Recent Publications

The following separates of Mineral Resources of the United States have been received:

ANTIMONY, ARSENIC, BISMUTH, SELENIUM, AND TELLURIUM, FOR 1915.

I-14, GOLD, SILVER, COPPER, LEAD, AND ZINC IN NEW MEXICO AND TEXAS IN 1915. By Charles W. Henderson; I-15, same in Utah, by V. C. Heikes; I-16, same in Colorado, by Charles W. Henderson; I-17, same in Arizona, by V. C. Heikes; I-18, same in Idaho and Washington, by C. N. Gerry; I-19, same in Montana, by V. C. Heikes; I-20, same in Nevada, by V. C. Heikes.

EDITORIAL

T. A. RICKARD, Editor

KIRKLAND LAKE is a gold-mining district of relatively recent date. It is one of Ontario's new discoveries and promises to be a worthy neighbor to Porcupine. We are glad to publish an authoritative article on the district by Mr. G. C. Bateman, manager for the La Rose Mines at Cobalt and Porcupine.

CABLEGRAMS are now subject to censorship. This does not prevent the use of certain well known commercial codes, such as the "A.B.C.", Scott's, Western Union, Lieber's, Bentley's, Broomhall's Imperial Combination, Riverside, and "A.Z." Plain-language messages may be written in English, French, or Spanish, subject to a few exceptions. We are at a loss to understand the specific exclusion of mining codes in the orders for regulating cable-correspondence.

METALLURGIC progress has been so rapid in recent years as to make the general review by Professor Francis A. Thomson, published on another page of this issue, particularly valuable. The more revolutionary changes have revolved around the wide extension of the flotation process to ores of copper, lead, and zinc. As a result the reverberatory furnace is superseding the blast-furnace in copper-smelting, and the rapid development of electrolytic zinc reduction has become necessary. That in turn offers a field for the treatment of complex sulphide ores, once more robbing the blast-furnace, and lending color to the statement, now often heard, that the pyro-metallurgy of copper is obsolescent.

CARRANZA by a decree dated April 5 has transferred control of mines and mining concessions from the Department of Fomento to the newly created Department of Industry and Commerce. Included in the same portfolio are affairs connected with petroleum and fuels, and concessions for their exploitation, beneficiation, and transport. Considering the socialistic nature of the constitution under which the new government has been organized in Mexico, it is fortunate that the same ministry has cognizance of trade-unions and of matters in dispute between labor and capital. Vexatious delays in the adjustment of difficulties may be avoided by having to deal with but a single department in all that concerns the government's relations to the mineral industry.

PATRIOTIC service is in the mind of every good citizen. Many members of the mining profession already have obtained commissions in the Army and others have made application. Therefore any first-hand in-

formation concerning the realities of warfare in Europe is sure to be interesting at this time. We are glad to publish an interview with a mining engineer that has served with the British field artillery. Mr. Morton Webster is known to most of our readers by reason of his writings on the subject of mine valuation. He left his office at New York to serve his native country at the beginning of the War, as stated in the interview. We may add that becoming a 'casualty' a second time, in Bulgaria, he had to accept the official decision of unfitness for further service and return to the practice of his profession. Here we venture to suggest that such men, invalidated from the front, ought to be valuable in giving instruction or advice to the volunteer officers now in training for taking part in the War.

REFINING of tin at the Perth Amboy plant of the American Smelting & Refining Company was mentioned in our issue of April 7. The wisdom of reducing tin in the country that is the largest consumer of the metal has become so clear that the Williams Harvey Corporation, an off-shoot of Williams, Harvey & Company, Ltd., of Cornwall, the most important firm of tin smelters in the world, has recently acquired a site at Mill Basin, Jamaica Bay, Long Island, where works will be erected immediately. The development of tin smelting as a permanent industry in the United States thus seems assured, and it must be credited as a direct result of the changes in trade relations brought about by the Panama Canal. When Bolivian tin concentrate had to be transported by way of the Straits of Magellan it was logical to take this product to Europe for treatment at the old-established refineries. It would be equally illogical to carry it through the Canal and almost within hailing distance of New York only to pay freight on the ingot back from England to America. The American Smelting & Refining Company gave the first demonstration of the commercial opportunity presented in applying this simple principle of conservation, and their competitors have acknowledged the point in a practical manner.

LAST week we reproduced some remarks made by Mr. Toyokichi Iyenaga at a public meeting at Philadelphia, suggesting that the peaceful relations of this country with Japan did not stand upon a secure footing. Apropos of that it is proper to take more than passing notice of the announcements just issued to the Japanese residents in America requesting all males between the ages of 17 and 45 to report to a person named therein, with the object of organizing a fully equipped army division "to fight for the United States." It is stated by Mr.

M. G. Yuasa and Mr. H. J. Wolff, who are active in the organization of the Japanese legion, that about 45,000 of the 80,000 men of that race in the United States are of suitable age, and have had military training. It will be recalled that the Allies declined the active co-operation of Japanese soldiers in Europe, and we also might correctly intimate that the organization of a Japanese army at this time is quite unnecessary. Assuredly the argument will hold with greater justification as applied to aliens, no matter how desirous they may be to fight for America, than it did against Colonel Roosevelt's proposal to raise a division of citizen-volunteers. If Japan choose to make a really serviceable proposal, indicative of the highest goodwill toward this country and toward her European allies, she might offer a portion of her rapidly growing merchant marine for the transmission of supplies from our ports to England and France in order to release an equal tonnage of American vessels for transporting troops to France and for maintaining them while there.

CHINA took a long look ahead when she elected to join our Allies; she was preparing to rend the ligaments with which Japan sought to bind her as a vassal. Very lucidly the situation has been explained by Mr. Hun Liang Huang in a recent address at Columbia University. China finds her grievance against the Central Powers in the paralysis of her European trade brought about by the submarine warfare. Taking advantage of this she secures a seat in the future peace council. Thereby she invokes the self-interest of the other powers, opposed to the aggressive exactions of Japan, in determining China's future status. Japan laid claim, by right of conquest, to the concessions and privileges that had been wrung from China by the Germans at the time of the original seizure of Kiao-chau. By offering her aid to the Entente, China obtains the assurance of material economic advantages. Revision of the tariff is conceded, liberating her from the arbitrary schedules imposed 17 years ago by the concert of European nations. Thus China will be able to collect *ad valorem* duties upon the actual market prices of articles of commerce, and in consequence her revenues will become adequate for the needs of a developing nation. This alone will be worth more to her than the costs and sacrifices she might be called upon to make as a result of participation in the War. The Chinese government has no expectation of contributing a contingent of troops, but it is interesting to note her proposal to furnish as many millions of laborers as may be needed, releasing an equal number of Europeans trained for effective military service. Rightly does Mr. Huang refer to this available army of workers as "an inexhaustible supply of human power." In addition it must be recalled that China is exceedingly rich in mineral resources, and can supply the Allies with arms and munitions more cheaply than Japan; indeed, the Japanese have depended mainly on China for the raw materials out of which were manufactured the supplies they have been furnishing to Russia.

Sulphuric Acid for Alkali Land

It is pleasing to record that the old feud between agriculture and smelting may be mitigated, if not actually set at rest, by an unexpected demand from the farmer for sulphuric acid in its normal vitriolic condition, unmodified by conversion into super-phosphate. Smoke-farming has long been a recognized industry, though a discreditable one. Smelters have retreated into secluded valleys and have occupied desolate alkali wastes to avoid doing injury to legitimate agriculture, but blackmailers have followed and taken up lands where the smelter-smoke would necessarily injure such crops as they might be able to raise. The collection of damages became in effect the equivalent of a market for an assumed potential output from the land. Not one of the smelting industries of the West has been free from this harrassment. Millions of dollars have been expended in litigation, and more millions have been paid to farmers within the zones of smoke-damage as a sort of annual commutation of the estimated losses. The suit against the Anaconda Copper Mining Company for damage done by its Washoe smelter has become a historic event; at one time the very existence of the enterprise was threatened by an injunction, but so great an establishment, with its contributory mines, upon which more than 25,000 people depended for a living, could not be closed. The principle of preponderating benefits finally governed. A different result followed in other places. The Mountain Copper Company in Shasta county, California, was seriously hampered by having to close its smelter at Keswick, and to haul its ore to San Francisco bay for reduction, while the Bully Hill, a profitable property when the output could be smelted at the mine-opening, was not of such magnitude as to admit of pursuing the course adopted by the Mountain Copper. It has remained closed for years, a loss to its owners and to the country. Strenuous efforts to overcome the difficulties presented by the fume have resulted in no broadly practical solution. If the sulphurous gas be converted into acid the problem of disposing of this by-product assumes a more serious aspect than that of diffusing the smoke into the atmosphere from the tops of lofty chimneys. The consumption of super-phosphate as a fertilizer has not yet become sufficiently large in the West to create a demand capable of absorbing an important amount of sulphuric acid. Even the high prices obtaining during the War, caused by the enormous increase in the output of explosives and in general chemical manufacturing, have not encouraged the development of an acid industry in Western mining regions, owing to the prohibitive cost of transportation. Even as a by-product from gases going to waste, and despite the payment of penalties in consequence, it is, nevertheless, not economically feasible to compete with Atlantic sea-board acid-plants that have at command raw materials from Louisiana, Texas, Spain, and Cuba.

The Middle-West zinc smelters, situated in the heart of rich farming areas, have been forced into the manu-

facture of acid, and they actually produce an important proportion of the present output of the country. The growth of agriculture in the West threatens to aggravate the difficulties of the copper and lead smelters unless a new outlet for acid be found. Therefore it is a matter of extraordinary interest to know that investigations by the Agricultural Experiment Station of the University of California have shown that remarkably advantageous results are derived from applying undiluted 66° Baumé sulphuric acid to alkali soils. The tests on small plots have been in progress for three seasons, with no discordant results, and with increasing promise of establishing the method as one that may find wide application throughout the semi-arid West. For the metallurgist the significant feature is the fact that the treatment requires from one to three tons of acid per acre and the area to which the method is likely to be suitable aggregates many millions of acres. It is said that a half-million acres in the San Joaquin valley in California alone would be benefited by it. These areas, moreover, happen to be coincident with the localities in which the principal Western smelters are situated. This is a fortunate combination, since the shortness of the haul from the centres of potential cheap-acid manufacture to the points where the acid is needed will greatly facilitate its use on a large scale.

Gypsum has been employed to neutralize the so-called 'black alkali' where an excess of sodium carbonate is present in the soil. The breaking up of the gypsum, however, is slow, and the effects are neither so prompt nor so thorough as those obtained by the direct use of sulphuric acid. The conversion of the sodium carbonate into sulphate is only a part of the benefit derived from the treatment. The physical condition of the soil is improved through the shrinkage of colloids. Furthermore the acid acts upon the chlorides, giving a double advantage. It has been shown in experiments conducted by the Division of Soil Chemistry of the College of Agriculture that when a large amount of sodium chloride has been leached away by irrigation the excess of resulting colloid leaves the soil impermeable to an extreme degree. Moreover, the sulphates formed are less toxic to plant-life than the chlorides originally present. The destruction of chlorides by sulphuric acid, in conjunction with its pronounced action as a flocculating agent, gives a wider field of use than that of merely neutralizing alkaline carbonates. It is said that when applying the acid from a sprinkling-cart the workmen are obliged to wear gas-masks as a protection against the chlorine evolved. The carbonization of organic matter in the soil, resulting from the application of sulphuric acid, would probably promote favorable conditions for the development of the bacteria that are useful in plant-growth. It is the expectation of those having the experiments in charge that one treatment by acid may in some cases prove a permanent corrective of the alkalinity of the soil; in other cases re-treatment at intervals may be required, since carbonates will be renewed, as well as brought to the surface by capillarity and concentrated there by evapora-

tion. In any event, considering that the total output of sulphuric acid in the United States in 1916 was 5,500,000 tons, and in 1914 was only 3,162,439 tons, a new use that may demand some millions of tons within the next few years is a matter of the highest importance to the Western smelters. The experiments will be watched with eager interest. So happy an alleviation of the fume-difficulty, in which the farmer and the smelter can join hands in mutual helpfulness, is something that had not been anticipated. It was a bold conception to use a strong mineral acid for the improvement of soils, but it proves to be based on sound chemical, physical, and biological reasoning. Lands previously encrusted with alkali, and quite unproductive, have been made to yield nearly two tons of barley-hay per acre following a single treatment by sulphuric acid. The method manifestly may be expected to create a market for acid having far greater possibilities in agriculture than the utilization of other forms of so-called smelter-waste.

Commercial Patriotism

Abnormality has put reason out of court in the metal market. The law of supply and demand has met an unforeseen contingency. Military necessity must decide prices in the immediate future, and no man can tell how far the restrictions of the Government may extend to the private transactions of commerce. The trend of prices for copper and lead is moderately but distinctly downward. It must be noted, however, that the price of copper is fixed by Mr. John D. Ryan and the Messrs. Guggenheim, and that of lead by the Messrs. Guggenheim alone. Only those who happen to be in the close confidence of these gentlemen are capable of reading any such significance into the price movements of the moment as will serve to interpret the future. Already it is evident that the offer of a limited quantity of copper to the Government at the average price of the past ten years lacks the merit of sustained patriotism. The complement to that splendid offer, made at a time when it warmed every American heart with responsive gratitude toward those volunteering pecuniary sacrifice for the country, would have been a continuing arrangement for lessening the financial burdens of preparation for the overthrow of the common enemy. It is not facing the facts of the War to discriminate between the United States and the Entente Allies in the existing crisis. It took our people long to recognize the truth that the Allies were fighting our battles, that their success meant our safety, their failure our undoing. The last lingering doubt of this in any mind must have been shattered by the recent revelations of Mr. James W. Gerard, who speaks with an authority that cannot be challenged. He tells us, from the vantage-point of an ambassador to the court of the Hohenzollerns, that Germany counted upon crushing England by means of submarine warfare, and then falling upon us in our state of impotent unpreparedness before we might have time to buckle on our armor. All this has much to do with metal prices. It means that the

selling of 45,000,000 pounds of copper at 16.6739 cents per pound is admirable only as a beginning of a patriotic sacrifice. Even to sell to the Government all that it may need for the next two years at that price is not meeting the necessities of the situation. It is not the Government that wages war; it is not the Government that overcomes a national foe; it is the people, co-ordinated for effective effort through the administrative organization. It is strange that a preachment, emphasizing primary fundamentals that should have been learned in the Montessori infant-school, should now be necessary, but it is clear that the public is confused between the guesses of speculators in the market and the mysterious movements of those who direct the market from behind. It is not with the product of the Government shops only that this war will be won, but with these plus the output of every factory in America, in England, and in France; it is on all of these together that the freedom of Mr. Ryan and of every metal-producer to continue his business depends in the future. When one of the controllers of copper production declares that "it would be unfair to consumers at home if European buyers [meaning the Allies] were allowed to take supplies at lower prices than they [our domestic buyers] were charged," it is time to call things by unpoetic names; it is time that we as patriotic Americans should call upon our sense of humor in explaining the industrial harvest we have reaped at the expense of struggling peoples across the Atlantic, and atone for it by taking at most a modest profit for such necessities of warfare as we shall provide. The principle involved is broader than national patriotism, and as such it must be understood and accepted. The producers of copper would be doing a greater service by facilitating the regulation of the prices of all commodities by a war commission, established for that purpose, than by creating sentiment against so sane a procedure. They do not show the right spirit in stating that, if metals are to be controlled, so should flour and butter and eggs, and then throwing out the sordid suggestion that, if such a propaganda were set on foot, "there would be so great a clamor that the project would be quickly dropped." As a matter of fact precisely such thorough-going administrative regulation of prices is provided for in the Lever bill just introduced into the House. On the other hand we are not prepared to adopt fully the reasoning of a correspondent, Mr. William E. L. Dilaway, in our issue of April 21, who sees in the generosity of the copper producers only a "thimble-rigging of mining companies by people who are willing to snuff the battle afar off provided they can short the stock-market." The opportunity for manipulation is there, coupled with the existence of a gullible public, but it is unfair to single out the copper producers for criticism; they are not alone in failing to recognize that the maintenance of high prices, even with reference to the un-preferred customers, combined with a straining of government credits both here and abroad, is the same thing in effect as forcing gold to a premium with its attendant evils of depreciated currency-value and financial disaster. In the phrase of the day, the purchasing power of gold has declined, but

it is all the same thing, and the baneful results are not modified by reading it backward or forward.

Until the great captains of the iron and steel industry see the light, and help to protect themselves and the country by sounding the note of alarm and by calling for co-operation in wise regulation of selling-prices and wages paid, we must withhold special censure of the masters of other metals. The aggravation of the situation through the attitude of the steel producers seems to us even more reprehensible. They likewise have posed as magnanimous patriots. They have won encomium, many of them, by submitting to what the public has been coached to believe is a kind of economic self-effacement in taking unlimited orders from the Government at actual cost of production plus a 'nominal' profit of 10%. In short, they are ready to deal with the most responsible of all customers on a guarantee of 10% upon cost of raw material, labor, depreciation, renewals, insurance, and all the rest. What safer deliverance from the ordinary vicissitudes of commerce could enter the dreams of the most optimistic manufacturer? Moreover, how is the Government protected against soaring prices by this arrangement? Sensational advances have taken place in bessemer, basic, foundry, and other grades of pig-iron. A year ago bessemer was selling around \$21 per ton; today it is quoted at \$43. Within the same period Connellsville furnace-coke has risen from \$2.65 to \$8 per ton. This is a measure of the general advance, and points the whole moral. So far-reaching are the co-ordinate industries affecting the ultimate cost-factor in the articles of common need, upon which hangs the strength and efficacy of our national defence, that the one sane way is to eliminate the whole wretched business of market speculation during our period of stress. One commodity cannot be boosted without shifting the centre of gravity of national industry. The inter-relations of commercial activities are such that they constitute an organic unit. The high price of steel-sheet means a more costly potato: it means increased financial suffering on the part of those who make the sacrifice of sending their loved protectors to the front; it casts the shadow of home-distress upon the soldier whose duty it is to fight for flag and country; the sense of the injustice of it chafes his spirit and can but affect his valor. He who counsels and supports high prices at this time comes very near to offering sacrifice to Moloch. To quote one price to the United States and another to our companions in arms, and then to charge the private buyer the higher price whereby that price directly or indirectly gets figured at last into the costs against the Government in other industries, not only savors of the ancient religiosity of robbing Peter to pay Paul, but injects the principle of the trade-war into the relations between the very nations now fighting, as we hope, for the abolition of this most fertile cause of international conflict. The sooner we all agree to protect ourselves and those with whom we are now linked in the universal struggle for civic and industrial freedom by rational price-regulation, the finer will be our service to the world and the richer our experience of active patriotism.

A Mining Engineer's Experience in the Artillery

AN INTERVIEW WITH MORTON WEBBER, BY T. A. RICKARD

Mr. Webber, you have seen service at the front recently, have you not?

My last active service was in December 1915, and I was finally invalided in May 1916.

Mr. Webber, will you say something about your experiences as an artillery officer in the War?

I dislike this sort of thing, for obvious reasons, and I have refused numerous requests to put my experience into print.

That is natural; but things are different now that America is in the War. There must be many mining engineers, eager to follow in your footsteps, that would like to hear about your experiences.

Yes, I have thought of that, and I shall be glad, in a small way, to help the good work along.

On what fronts have you fought?

In Flanders, in the Gallipoli peninsula, and in Bulgaria.

When did you join?

I left New York, where I was in practice as a mining engineer, in November 1914, proceeding to London with the intention of obtaining a commission in a Scotch regiment, as I had several relatives in Scotch regiments, including the honorary colonel of the Argyll and Sutherland Highlanders, but, as you will recall, I had a talk with you on my arrival in London, and you urged me to join the Field Artillery. Your letter of introduction enabled me to obtain a commission in December 1914. I was sent to the reserve depot near Exeter, in Devonshire, and underwent training as an artillery officer for two months before being sent to Flanders to replace a casualty.

To what part of the line did you go?

To the Ypres salient, where my battery was engaged in the fighting at Hill 60. After being there four weeks, I was wounded in the leg by a shrapnel bullet, and invalided to England.

Will you say something about your experience at Ypres, stating such facts as would interest your friends in the mining profession?

There is nothing technical I could say except that I was there at the very worst time, when we were quite inadequately equipped, having few high-explosive shells with which to demolish German trenches and emplacements.

Then shrapnel is no good against a gun-emplacement?

Not unless you can register a direct hit, which is seldom done; for example, suppose a German battery was firing at our emplacements with high-explosive shells that

burst within 30 yards of us, the result was generally effective, whereas if we engaged them with shrapnel in reply—as we had to do—we had either to register a direct hit on their emplacements or we merely peppered the emplacements with shrapnel, which did little damage.

What do you mean by an emplacement?

The emplacement may be an earthwork around a gun or it may be a structure built of concrete, sand-bags, or even steel plates.

Did you find your experience as a mining engineer of any use to you?

I found my training as a mining engineer of the greatest value, because practically all modern artillery engagements depend upon what is known as 'indirect' fire, which is a process of triangulation. The average civilian who attempts to become an artillery officer has to start from the ground up. It was because I had received this knowledge that I was sent to France within two months; the ordinary training takes about six months. In short, I found little difficulty in applying range-finding methods. Furthermore, of course, my experience as a mining engineer made me familiar with the nature of explosives and particularly the directing of men; also it may be of interest to state that in our brigade there was a large proportion of Welsh colliers, whom I understood much better than my fellow-officers. I was a section-commander, so I soon had a number of sturdy Welsh coalminers under my command.

In regard to horses, had you been accustomed to them?

Yes, I had been accustomed to horses most of my life, not only as regards the use of them for draft, but I had done a good deal of steeple-chasing and riding to hounds when a boy in Devonshire.

Did you lose many horses in the course of your campaigns?

I lost eight altogether, all of which, except one, were shot. Fortunately they were shot when I was not riding them, except one, and he rolled on me so that I was laid up for about three weeks in a field-hospital.

On returning from Flanders, how long were you in England?

I was in hospital about nine weeks, and then I was sent in command of a detachment of about 100 gunners to Alexandria, where I was made section-commander in the artillery of another division.

Where were you stationed?

First at Aboukir, then my battery was loaned for the defense of the harbor at Alexandria.

How did it happen that a field battery was so employed?

Because the harbor fortifications had been built before the day of the submarine, more particularly prior to submarines being supplied with 4-in. quick-firing guns. It was discovered that it was possible for an enemy submarine to approach under water and to rise within the maximum depression of the guns of the fortifications and therefore to do enormous damage to the congested shipping in the harbor. My section was posted so as to command one leg of the breakwater and the other section of a battery was posted so that it could command the other leg.

I think you told me something about an experience with spies?

Oh yes; my section was posted close to the Raseltin Yacht Club, which is one of the fashionable clubs of Egypt; I was made an honorary member and went there for meals, so that I met a good many people, among others, a fashionable lady, who, under guise of patriotic hospitality, entertained me. I confess that I was curious as to her motives, and particularly skeptical of her sympathy. One day she asked me, as if by accident, where our observation-station was. This question from a woman indicated a knowledge of modern gunnery that was unusual, and I immediately became cautious. I debated in my mind whether I would shut up or play the part of a fool, and I decided that the latter would be the easier. So I told her that it was the steeple of the English church, which, of course, it was not. After that, we were interested to see if a German submarine would come and take a crack at the English church, but our torpedo-destroyer defense outside the harbor was too effective. Subsequently this lady dropped me, as she supposed she had the desired information, and started the same game with a remount officer, whom I took occasion to warn.

You did not stay in Egypt long?

No; after the coast-defense people erected quick-firing guns as permanent structures, my battery re-joined our brigade at Aboukir, and soon afterward—in June 1915—we were sent to the Gallipoli peninsula.

So you took part in the campaign there?

Yes, I was there until September. During those four months we had continuous fighting day and night; that is, we were shelled continuously by day and night. Our position was most precarious.

Will you kindly say something about your experience as an artillery officer at Gallipoli?

Our great difficulty was that owing to the topography we were unable effectively to shell the Turkish trenches, because they were, in many cases, on reverse slopes.

What is the effect of having a trench on the reverse slope?

A reverse-slope trench means that it is situated on the other side of the sky-line. It was impossible for us at such short range—say, up to 2000 yards—to get the angle of descent necessary to shell the enemy effectively. We could not put our guns farther back, in order to get the necessary angle of descent, because of the sea, where-

as the Germans could withdraw their batteries to any convenient distance inland in order to get the proper angle of descent; so their fire was much more effective than ours. In this statement I am touching on what I believe to be one of the principal causes of our failure at Gallipoli. The enemy's artillery, as I say, shelled us day and night, which, especially during the hottest time of the year, was most trying. I may say that for four months I think that no person in the Expeditionary Force had three unbroken hours of sleep. All our guns had to be man-hauled during the dark, there being no place where we could get cover for our horses. This failure in effective shell-fire was what caused the enormous casualties that we had to suffer, inasmuch as when we attacked an enemy trench our infantry came up on the sky-line, exposing themselves to fire from Turkish trenches on the reverse slope that practically had been undisturbed, whereas we had to cease our shrapnel-fire at the very moment when it was most needed because we would inflict more casualties on our own men than on the enemy as illustrated by Fig. 1.

The Turkish batteries were commanded by Germans and Austrians?

Almost entirely.

What were your approximate casualties?

I cannot answer that question, as there are some things which you will understand I cannot go into, but I may say that in approximately ten square miles we lost half the total casualties in France in half that time.

This is appalling; what was the cause of it?

I have already endeavored to explain how ineffectual our artillery was because the topographic conditions were entirely in favor of the enemy; also, the enemy instituted a practice of destroying their traverses before abandoning their trenches. You will understand that a modern trench is never continuously straight; it is straight for a certain distance—say, 30 yards—and then it has a bend—of 5 yards radius—and is straight again to the next bend. These bends are called 'traverses.' This is done to prevent enfilading by machine-guns or other gun-fire; in other words, to restrict the effect of such fire to a short length of the trench. The Turks, when they had decided they had to give up a trench, dug through these traverses, as I have explained, and constructed machine-gun bulkheads at both ends. Our infantry then attacked the trench, captured it, and became exposed to such machine-gun fire. In this way entire regiments were decimated. (See Fig. 1 and 2).

Surely this was not done often?

It was very difficult to prevent, for the reason that I have already given, namely, our artillery could not demolish a trench before we took it. It was essentially a fight between machine-guns under cover and our men in the open. Of course, all this is past history, otherwise I would not be at liberty to tell you about it.

You yourself were not wounded at Gallipoli?

No; I was particularly lucky.

Why did you leave in September?

At that time General Sarrail made the original landing at Salonika, and as he was short of field-guns, our brigade was loaned to him, and with him we went on the original Balkan expedition.

How many guns are there in a battery?

There are four guns in a Field Artillery battery, about 150 horses, and 150 men.

I thought there used to be six guns.

That is so, but then there were only three batteries to

corps consists of 80,000 men as against the British army corps of 40,000.

How far did you penetrate into Bulgaria?

We drove the Bulgarians out of Serbia, across the Vardar river, into Bulgaria. Both belligerents finally took up winter positions in a mountainous country, very much like Colorado. My battery—

You had been promoted?

Yes; I had become captain. My battery was on top of a mountain where we had to man-haul our guns in the

DIAGRAMS SHOWING CONSTRUCTION OF TRENCHES

a brigade and now there are four batteries to a brigade. This re-arrangement has many advantages, which I need not discuss.

So you became part of the first Anglo-French expeditionary force that invaded Bulgaria?

Yes, and here I may say that the misfortunes of the

dark, and our horses were three miles in the rear in a valley where they could get water and cover.

This must have put you to a great disadvantage?

Yes; because in event of a retreat, there was no way of getting our horses up to our guns, because the line of communication was completely 'registered' by enemy

FIG. 3. A. BRITISH GUNS. B AND D. BRITISH. C. TURKS. E.T. ENEMY TRAJECTORY. B.T. BRITISH TRAJECTORY

Gallipoli campaign were due in part to a breach of faith by the Greeks, for it was understood that they would land an army immediately our fleet began the bombardment at the Dardanelles. The Greeks not only failed to carry out their bargain, but they adopted an unfriendly attitude, called "benevolent neutrality." I was very much amused to observe that we landed at Salonika under the protection of at least ten of our own battle-ships, out in the harbor, so as to make the Greek neutrality as benevolent as possible. On our return from the expedition, which was driven back by an overwhelming force, the Greeks threatened to intern us if we returned as a fighting force, whereupon when we did return we arranged a formation called 'form starfish,' the object of which was to be able to fight on all sides.

So you had a hard time?

Yes. Our front was attacked by two Bulgarian army corps, making 160,000, while our force consisted of 15,000 only. I should explain that a Bulgarian army

batteries. This was the farthest point we got; the Bulgars were able to mass in overwhelming force, as I have stated. They literally swamped us. It was necessary to sacrifice the guns to enable the infantry to retire; in other words, we had to hold our ground while the infantry withdrew, as against the usual method of withdrawing the guns by stages, prior to the infantry.

What happened?

Two of my guns were knocked out by direct hits, and we man-hauled the other two guns down the mountain in the dark. In doing so, the spokes of one of the guns was so badly shot away that we lost that gun also; the fourth gun, however, we did save, and were able to haul away as soon as we got our horses. Out of my 150 men about 30 remained. I then had a most unwieldy force, namely, 1 gun, 30 men, and 150 horses.

What did you do?

That was the end of my battery, because my Colonel told me it was no use 'carrying on' in this way, so my

horses and my men were distributed over the remainder of the brigade, and I replaced a casualty in another battery. Then the remaining two batteries of our brigade took up rear-guard positions alternately on the Rabrovo Pass—in Serbia—to protect the retreat of the infantry. This was accomplished successfully, and we made the enemy more than pay his pound of flesh. I may add that this was the first time in my military experience that I was fighting with the odds about even. It had been a one-sided show in France, a more than one-sided show in Gallipoli, and even worse in Bulgaria. Through the hottest months of the year at Gallipoli my men fought stripped to the waist; then they were sent to the Balkan snows without tents.

How do you account for this pitiful affair?

For the very good reason that Great Britain was not prepared for war, and Lord Kitchener was forced to kite checks of human lives.

You mean that Kitchener had to organize expeditionary forces of a forlorn kind, for political purposes, during the first period of the War?

Exactly. We were asked by Russia to make a demonstration at the Dardanelles, although there was no reasonable expectation of success after the Greeks had failed to land an army at the time of the naval bombardment. We went there with the sole object of localizing the Turkish army; in the same way we went on the hopeless first Balkan expedition with the object of menacing the line of communication between Berlin and Constantinople. This may emphasize what I mean by Kitchener being forced through necessity to "kite checks of human lives." I think this is a point that you people in America have not appreciated.

So you were scuppered finally?

Yes, while defending the Rabrovo Pass, on December 6, a gun in my battery received a direct hit and a splinter of it struck me in the back inflicting a wound that involved serious complications.

Was your ambulance service well organized?

It was impossible to have any ambulance organization as we retreated 80 miles in 4½ days, fighting continuous rear-guard actions.

Wounded as you were, why were you not made a prisoner?

Because my groom, a fine fellow, got me on one of my own horses and kept me on it until I reached a base-hospital. I was kept on a hospital-ship at Salonika about three weeks before being removed to a hospital at Malta, where I remained for about six weeks, finally reaching England in March 1916. The authorities decided that I was unfit for further active service, whereupon I tried to get into the French artillery, but as I had no knowledge of French, they would not take me.

Could you say something about your method of reconnaissance? As I understand it, 'indirect' firing means that those at the guns of a battery do not see the target they are aiming at. Is that right?

Yes.

Then, how is it possible to know what you are hitting, and, first of all, to ascertain the exact position of the object of your aim?

Generally the target, while not visible to the battery, is observed from some elevated position on the flank, or possibly directly in the line of fire, such as a first-line trench. Firing is directed from this point by an observation officer, and it is in working out this triangulation that the principles of trigonometry are used. However, the enemy's base, including such objects of attack as an ammunition depot, can only be located by aviation.

So the artillery officer has to make an aeroplane reconnaissance?

Yes, and it may represent a very important part of his work.

Did you do any of it?

Certainly, I was chosen for this work often, because of my small weight, especially when we were working in co-operation with a heavy battery behind us. For example, three of us would go up in an aeroplane.

What three?

My pilot, myself, and the telephonist. Our duties were as follows: the pilot was in charge of the machine; he had to go where he was told, and used his best endeavor to avoid being brought down by the enemy; the observation officer works in conjunction with his telephonist and through him sends instructions to the battery with which he is co-operating, either by wireless or by flashes.

By a 'telephonist' is meant a telegrapher, I presume?

Yes, if you like.

How does he get a reply?

If the aeroplane is supplied with wireless apparatus, the observation officer sends his orders by this means, and receives acknowledgment, usually by heliograph, because the wireless apparatus on the aeroplane, on account of its lightness, is able to send but not receive messages. The idea is to switch one of your own heavy guns, by means of locating the 'bursts' of its shells, onto an enemy base, or to establish a new register on enemy arteries of supply, which thereafter can be shelled at irregular intervals. For instance, the first time that I went up, it was with the object of locating an enemy base behind a range of hills. We flew over this range at a height of about 10,000 ft. to keep out of the reach of rifle-bullets, and were able to locate what seemed to be the preparation of an ammunition depot and a mule-transport depot belonging to the Bulgars, and also a bridge over a gulch, which we were able later to destroy by means of gun-fire.

Did the enemy fire at you while you were in the air?

Yes, they did, but I was so absorbed in my work, looking through my field-glasses, that I did not know anything about it until after we came down, and I could see that there were holes in the wings of the plane. I need hardly say that when engaged in this sort of work the idea of danger hardly arises, as the observer is so busy

and the noise of the aeroplane-engine is so great that he cannot hear the bursting of shells near him.

What kind of glasses did you use?

Prismatic field-glasses, with a very large field of view. Here I might advise young officers to avoid buying a glass of more than six magnifications, because as the magnification is increased the field of view is diminished—a vital defect—and the strain on the eye is greatly increased.

Did you take turns in observation, or in what manner is the observation officer selected for this dangerous duty?

It depends upon a man's aptitude for such work. Again, in this branch of the service, the training of an engineer is of value, as he may be asked to make sketches of what he sees.

For a ground observation, how do you select officers.

As a general rule, each battery has its own observation officer, and the officers of a battery should perform this duty in turn, as it is very trying and decidedly the most dangerous work that an artillery officer is called upon to perform, because, of course, the enemy is always looking for observation stations, these being the eyes of the batteries. This work should be done in relays, otherwise the nervous system won't stand the strain.

Would you describe an example of such observation work on the ground as distinguished from your air reconnaissance?

When in command of my battery in Bulgaria, we used a house in a destroyed Bulgar village, on top of a mountain. I went there in the dark, with my servant and two telephonists, staying there until the following night, when I was relieved by an officer and his relay. From our point of vantage we could see all the Bulgar trenches, and were able to direct our fire.

Were you not exposed to sniping or shell-fire?

We were out of danger of rifle-fire, but as the Bulgarians could not hold this village, they made up their minds we should not have it, and they shelled the village every three hours. Of course, they did not know which house we were in, but, in true German style, they sent over about seven shells every three hours; in fact, we could tell what hour of night it was by the time they came through.

By the way, the phrase 'curtain of fire' appears in the daily press frequently. Would you kindly explain it?

Imagine a trench that we desire to take. A given brigade will attend to a section of trench, 300 to 500 yards long, and shell it within an area of that length by 100 yards deep. This imaginary rectangle runs lengthwise of the enemy trench, which is relatively near the nearer long side of the rectangle, in order that the splash of our shrapnel may just reach the enemy and compel him to remain under cover so that he cannot use his rifles on our infantry when they advance. Meanwhile the fire on the two short sides of the rectangle and on the back

line of the rectangle prevents the enemy in this section of trench from receiving any reinforcement. This is called a 'curtain of fire,' although to a layman it may seem more like a quadrilateral. The observation officer, as he sees his infantry advancing to just short of the zone of dispersion of his own shrapnel-bullets, sends the order to his battery "add 100"; the battery thereupon advances its fire that much and makes a double line of exploding shells behind the enemy. Our men then go into the trench with their bayonets and bombs.

During this operation, how many shots per minute does a field-gun fire?

From 12 to 18 shots per minute, or a shot per second per battery.

How long can they maintain this before the gun becomes too hot?

I have never seen a field-gun become too hot, if you mean become hot enough to cause a premature explosion in the barrel. This kind of work is limited by the ability to bring shells to the guns, as the modern field-gun has outstripped any process of supplying ammunition. By the way, these curtains of fire are always made by field-guns, and by no other, so you can guess what an important part they play in the War.

You would recommend members of the mining profession to join the artillery?

Most decidedly, but if they are not familiar with horses they should not attempt to go into the field artillery, but should join the heavy artillery. By 'heavy' is meant anything bigger than the field-guns. All armies have a field-gun, which is drawn by horses and is supposed to gallop into action.

Of what calibre are these guns?

The British field-gun is of 3.2 inch calibre and fires an 18½-lb. projectile; the American field-gun fires a 15-lb. projectile, and the French 75-mm. gun fires approximately the same weight of projectile. I might recommend mining engineers that want to 'do their bit' to become identified with as heavy artillery as possible. By this I mean guns of more than 6-inch calibre.

Why is this?

Because such a gun may be in the same position for a month at a time, and it is possible for the officers to dig themselves in, erect structures for their accommodation, and become quite comfortable away from rifle-fire—the *bête noire* of the gunner. The 'heavies' have the easiest time of the whole fighting force, whereas a field-battery, especially in an engagement of moving forces, may have to take up four or five different positions during a single day, and one never knows where one is going to sleep next. Of course, what I said just now was intended to be humorous. I feel sure that our mining engineers will seek not the most comfortable but the most effective service in their power, but I do not recommend a mining engineer to join the Field Artillery unless he has a knowledge of horses and is a good horseman himself, otherwise he will be at a considerable disadvantage.

Five Years of Metallurgical Progress

By FRANCIS A. THOMSON

Five years is a brief period in the history of an art, yet it is doubtful whether any similar interval of time, even including those eventful days in the early nineties when cyanidation was making its triumphal entry, can show as many momentous metallurgical improvements as are to be credited to the five years preceeding 1917. Exceeding all other metallurgical events in significance, actual or potential, stands the progress of froth flotation. Five years ago all were skeptical, and timidly inclined to place this along with hundreds of other moribund patent processes. This was a mistake. Today flotation ranks as the leading single process of ore treatment, no other method equalling it in tonnage handled. The amount of ore treated by the major processes in use in the United States is about as follows:

Treatment	Tons per annum
Flotation	30,000,000
Copper smelting	26,000,000
Gravity concentration	25,000,000
Gold and silver milling.....	13,000,000
Lead smelting	5,500,000
Copper leaching	2,000,000
Zinc smelting	1,000,000

About the same ratios apply to world production, except that the proportion treated by copper smelters will be less and by gold mills greater than here given. The annual capacity of the world's flotation plants is approximately 50,000,000 tons.

It is easier to enumerate the ores to which flotation is not adaptable than those to which it applies. Gold, silver, copper, lead, zinc, molybdenum, cinnabar, tungsten, and many more are being successfully handled, and it is proposed to use the process for the recovery of substances as far apart as flour-gold and anthracite coal. Truly, the process that the experts rejected has become the leading one in the art.

The influences exerted by the introduction of flotation are manifest in several ways: (1) by the simplifying of mill flow-sheets and increasing the extractions, as, for example, 82% is about the best extraction attainable by gravity concentration on average sulphide copper ore, while 96% may be recovered by flotation with a less complex plant and lower cost. (2) By making possible the beneficiation of ores hitherto not amenable to concentration, such as the sulphide silver ores of Mexico and the South-west. (3) By forcing vital changes in methods for the recovery of metals for concentration products. The latter is illustrated by the sudden extension of the use of the reverberatory furnace in copper smelting, since it is virtually impossible to treat the flour-like flotation-concentrate in a blast-furnace which has a gale of wind blowing through it. Another illustration is afforded by that

of the treatment of flotation concentrates for zinc recovery in retort-furnaces, the effect of which is that of turning the scales in favor of electrolytic zinc. In lead smelting, the already established sinter-roasters have saved the day. Without them the lead metallurgist would have been overwhelmed by the volumes of film flotation-concentrate that has been coming his way. The success of flotation is understood to have changed the entire plans of the Anaconda Copper Mining Company. They abandoned their great leaching project for sulphide ores, in favor of the newer process.

That flotation has its limitations and that attempts have been and will be made to apply it to ores better suited to treatment by other processes, is natural, but at present we have not discovered its limitations. One scheme which looks doubtful on the face of it is the proposal to convert the copper in oxide ores back to a sulphide by chemical means and then to float the artificial sulphides. This savors of needless and unnecessary complication. It is, however, evident that flotation has not only come to stay, but that it will continue to grow in the matter of tonnage treated, stupendous as that present tonnage is.

Next in significance to flotation may be placed the electrolytic process for the recovery of zinc. All know the process. The zinc concentrate is roasted; then leached with sulphuric acid made from the roasting-furnace gases; the solution after purification is electrolyzed, and the zinc precipitated on aluminum cathode-sheets, stripped, and melted into ingots. Such zinc on account of its exceptional purity commands a premium of 1½ to 2c. per pound over spelter produced in the ordinary way by distillation in retort furnaces. In spite of protests by those engaged in retort-smelting, the process has proved successful and is destined to make zinc distillation look to its laurels, if in fact it does not eventually replace it entirely. Zinc smelting has long been criticized on the score of the initial high cost of plant, the high labor-cost in operation, and excessive consumption of fuel.

The extremely fine state of pulverization of the zinc-flotation concentrate has added another difficulty to the distillation process, such material tending to pack in the retorts, with the result that retort explosions frequently occur. This fine material, on the other hand, is well adapted for the electrolytic process. At Great Falls the Anaconda Copper Mining Co. has recently begun the production of electrolytic zinc from a plant which will soon have a capacity of more than 200 tons of metallic zinc daily. At Trail the Consolidated Mining & Smelting Co. is producing 75 tons of spelter by practically the same process. Numerous other plants are in construc-

tion, and in Tasmania a plant is being erected for the treatment of zinc ores from the Broken Hill Mines of Australia, the product of which, prior to the War, was the basis of the German and Belgian zinc industry. A great advantage possessed by the electrolytic process is its ability to treat lower-grade ores, and those that are more complex, than is possible by the fire-method. Western lead mines have long suffered from zinc penalties imposed on ores shipped to lead smelters. When electrolytic-zinc equipment becomes part of the necessary plant at a lead smelter, as at Trail, the presence of a high zinc-content in lead ore will mean a profit instead of a penalty. There are unsolved problems connected with the treatment of the melting-furnace dross and of the lixiviation residue. At Trail it goes to the lead furnaces. With non-lead ores the problem is not so simple. In any event the electrolytic production of zinc, following the leaching of roasted ore, is a distinct success. It may replace retort-treatment entirely, or it may not, but the retort smelters have to face a process already making appreciable inroads on their business.

In copper metallurgy, during the past five years, leaching has made rapid strides. Sulphuric-acid leaching of accumulated tailing is being applied at Anaconda, where 2000 tons per day is being handled. In Arizona the Ajo plant is just starting, where semi-oxidized copper ore is leached with 10% sulphuric acid in tanks 88 by 88 ft. and 15 ft. deep. Many other copper companies are supplementing their regular treatment of sulphide ore by lixiviation for the oxidized material. In several South American plants leaching is successfully employed, notably at Chuquicamata, where a 10,000-ton unit, the first of four, is in operation. The leaching is being conducted in concrete tanks 110 by 160 ft. and 16 ft. deep. At the Calumet & Hecla in Michigan, a 1000-ton plant is treating native copper ore by leaching with a solution that owes its activity mainly to ammonia and ammonium carbonate. The ammonia is later recovered by distillation and the copper thereby precipitated. This process was developed from the bottle stage in the laboratory to the present 2000-ton plant, in four years by the company's staff, assisted by the chemists of the Semet-Solvay Company.

Flotation has naturally checked any tendency to leach lean sulphide-copper ores. It is, however, a question whether roasting and acid-leaching of flotation concentrate may not seriously invade the field of the reverberatory furnace for copper recovery. This brings up the consideration of the changes during the half-decade in reverberatory-smelting practice. In 1911 oil-firing had become established wherever cheap fuel-oil was available. This led to a revival of attempts to burn pulverized coal in reverberatory plants where, owing to transportation costs, oil was at a disadvantage. First successfully accomplished in Canada at the plant of the International Nickel Co., the practice has been taken up at Anaconda with remarkable results, the capacity of the furnace, after slight enlargement, being doubled with practically the same fuel-consumption; or, stated differently, where

one ton of coal smelted four tons of ore it now smelts seven. It has been found that the previous failures in coal-dust firing had been due mainly to insufficient pulverization. At least 75% must pass a 200-mesh screen, and this involves drying before crushing. The pulverized coal is blown into the furnace through a nozzle by means of a fan, and burns as easily as gas. This and other improvements have reduced the cost of reverberatory smelting 50c. per ton. This, taken in conjunction with the success of flotation, threatens to leave to the blast-furnace a narrowly constricted field.

Again, in copper metallurgy, converter-practice has seen a complete and revolutionary change in the last five years. Prior to that time the vessels in which the metal was blown to blister were lined with silicious material, which was consumed as a flux by the iron oxide liberated during the operation. Consequently frequent re-linings were necessary; in fact it was figured that each lining was good for about 20 tons of copper. Today, by the substitution of a basic lining for the silicious one formerly used, the production of copper for each re-lining has been as high as 20,000 tons. The lining is usually of magnesite brick, with a protective coating of magnesite artificially deposited by careful manipulation of the first charge. The silica for slagging the oxide-bases liberated in blowing is furnished by charging raw ore direct to the converter. Basic lining has permitted the use of larger units, has decreased the time of the operation, and hence the labor-cost per ton, and it has dispensed with the large and expensive force constantly required for the work of re-lining. It has been remarked that the new converter-plants present a deserted appearance by contrast with those of five years ago.

In the metallurgy of gold, of silver, and of lead there is little to record. Each of these seems to have reached a plateau in its development. Aside from the ubiquitous influence of flotation the progress has been slight. In silver metallurgy the rebellious ores of Nipissing have necessitated the development of a novel plan of desulphurizing with the aid of metallic aluminum prior to cyaniding, but it has not met with general application. Flotation may prove to be better. It looks as if there may be keen competition between cyanidation and flotation in the treatment of gold and silver ores during the next few years, with the odds on cyanide for gold and on flotation for silver.

In the field of ore-crushing as a preliminary to concentration, the tube-mill, viewed askance a few years ago, has found general adoption either in the conical or the short cylindrical form. American metallurgists have awakened to the advantages of the ball-mill, so long advocated by European and Australian engineers, and as usual they have improved the type, so that the short cylindrical or conical mill with alloy-steel balls will apparently displace other re-grinding devices.

Another field of metallurgical enterprise remains to be mentioned, that of by-product recovery. The days when smelters discharged into the atmosphere great tonnages of fume and dust are passing. With facilities

for the recovery of sulphuric acid from roasting-furnaces, and with an increased use for the acid as a lixiviant, an impetus has been given to the conserving of sulphur. With the development of careful methods for measurement of stock-losses lead and copper smelters, especially the former, have been able to determine their losses, and either with the baghouse or with Cottrell tubes have proceeded to stop the waste. The effect is an extension of the practice of by-product conservation.

If one dared to venture into the field of prophecy he would predict the growth of flotation and of hydro-metallurgy, with a gradual encroachment of these upon the realm of pyro-metallurgy. The most significant feature of the progress here reviewed is that practically all of it has occurred west of the Rocky Mountains, under the direction of American and Canadian engineers and metallurgists, and as the result of sound technical training preceding their experience in practical application.

Rocks Forced Apart by Crystal Growth

*Many theories have been advanced to explain the origin of cross-fibre veins, particularly those of chrysotile. Most of these presuppose the existence of open fissures in which the vein minerals were deposited. It is conceivable that some cross-fibre veins may have been formed in pre-existing fissures, but in most cases this is mechanically impossible. In many instances there is evidence that the formation of chrysotile veins and the alteration of the enclosing rock to form massive serpentine, were contemporaneous processes; but the alteration of a rock to serpentine is usually accompanied by an increase in volume sufficient to close all appreciable openings. It has been suggested that chrysotile veins may have been formed by some process of replacement, but no one has explained why serpentine should replace serpentine of identical chemical composition. Moreover, chrysotile veins never contain pseudomorphs nor show trace of an inherited structure. Replacement veins are characterized by great irregularity in width and a lack of definite boundaries, while chrysotile veins are sometimes remarkably uniform in width, and always have well defined walls that are easily separable from the veins.

Cross-fibre veins with structural features similar to those found in rocks have been produced in the laboratory where their formation and growth could be observed. The evidence thus obtained supplements that furnished by veins of fibrous minerals, and makes inevitable the conclusion that cross-fibre veins are formed through a process of lateral secretion, the growing veins making room for themselves by pushing apart the enclosing walls. The force that enables the growing veins to push apart their walls is not due to the tendency of a crystalline substance to assume a regular polyhedral form, for the columnar or fibrous structure of most minerals occurring in cross-fibre veins is not a crystallization property, but is caused by the conditions of growth. Under similar

conditions the fibrous structure will develop in substances that crystallize in any of the systems of crystallization. When a substance separates from solution with increase in volume, the pressure developed depends on the magnitude of the forces resisting expansion, and may be much greater than the force required to crush the substance. It is improbable that pressure alone can expel solutions occupying sub-capillary pores in rocks, and in serpentine and other rocks found enclosing cross-fibre veins, the openings are almost entirely sub-capillary in size. In such cases the transfer of material to the growing vein is probably due to diffusion rather than to circulation. The fibres are always parallel to one another and extend in the direction in which the walls moved as they were pushed apart by vein-growth. In most veins the fibres are normal to the walls because the latter have been forced directly apart, but when the walls have had also a lateral displacement, because of the simultaneous growth of adjacent non-parallel veins, or from other causes, the fibres grow in the direction of the resultant motion. If the course of the vein is not straight, the fibres may be normal to the walls at one place and oblique at another. As long as the relative motion of the walls of a growing vein is in a straight line, the fibres are straight; any change in the direction of motion is immediately recorded by the slowly lengthening fibres. If the change in the direction of relative motion is gradual and continuous the fibres are curved; if abrupt, it results in the development of sharp bends. Sometimes the fibres of a chrysotile vein record several changes in the relative movement of the walls, and this gives a banded appearance due to the unequal reflection of light where the fibres run in different directions. The fibrous structure is to be attributed largely to the mechanical limitation of crystal-growth through the addition of new material in only one direction. In the case of the asbestiform minerals the fibrous structure is accentuated by a normal prismatic habit and cleavage.

Methods of Producing Sulphuric Acid in Germany

The production of sulphuric acid or sulphuric anhydride in Germany from plaster of paris in an electric furnace is vouched for by the eminent French chemist, M. Cazeneuve. The Germans are also treating plaster of paris with sand, producing silicate of lime and cement at the same time as sulphurous acid. Since the War Germany has had to look about for sulphur with which to make sulphuric acid, which partly explains the new process. Before the War Germany imported each year about 900,000 tons of pyrite from Spain for making sulphuric acid, and about 300,000 tons was mined in Germany. In 1912 and 1913 1,200,000 tons was imported each year from Spain. Besides these imports about 400,000 tons per year came from Norway, but this supply is not now available. Small quantities are probably now obtainable from Poland, Greece, and Turkey.

KIRKLAND LAKE MINE

The Kirkland Lake Gold District

By G. C. BATEMAN

Prior to 1910 gold was being mined in the province of Ontario at a few places only, and the production was small. In that year, however, development was started on a number of Porcupine properties, and when sufficient work had shown that the orebodies in that district would become important producers, search for new gold-bearing areas was extended to other parts of the Temiskaming district, so that discoveries were soon made at Swastika, Kirkland Lake, Long Lake, Munro township, and other localities in northern Ontario. The gold output from Ontario now represents more than half the total production of Canada.

Porcupine, with a yield of \$9,397,536 in 1916, is, of course, the most important gold-mining district of Ontario, but Kirkland Lake, although it has only a small production at present (\$702,761 in 1916), is developing rapidly. Taking into consideration the number of promising properties now being opened, it is easily the second most important gold camp in Canada. It may never rival Porcupine in tonnage or gross production, but it is of decided interest on account of the character of the ore, the geological conditions, and the number of properties that have been proved with a small amount of work.

The Kirkland Lake area lies in the district of Temiskaming, about 50 miles north of Cobalt, and 390 miles distant from Toronto. It is four miles from the town of Swastika on the main line of the T. & N. O. railway, and the properties being developed are in the townships of Teek and Lebel. The district is situated just south of the watershed between Hudson's Bay and the St. Lawrence river, and has an average elevation of 1050 ft. The country is rocky and hilly, but the hills seldom exceed 100 ft. in height. It is well wooded with spruce,

poplar, birch, and pitch-pine, and as there is a large number of swampy areas, prospecting is somewhat difficult. The timber is suitable for mining purposes, buildings, and fuel. Kirkland Lake itself is of considerable size, and much more than sufficient to supply water for the entire district. The first staking of claims was done in 1908-9 by prospectors who came from the Larder Lake district, 15 miles to the east. A number of claims was staked in the areas containing the Temiskaming series of conglomerates, with the hope that cobalt-silver veins, similar to those at Cobalt, would be found. Feldspar-porphyry was new to the prospectors at that time, so they paid little attention to the Kirkland Lake area. The first discovery of ore was made on the Wright-Har Graves property in 1910, and in the following year an attempt was made at core-drilling with a shot-drill. Owing to the extreme hardness of the feldspar-porphyry, this was abandoned after two shallow holes had been put down. In 1912 gold was found on the Tough-Oakes property by the Tough brothers and Harry Oakes. Other gold-quartz veins were soon uncovered on the Teek Hughes, Lake Shore, Sylvanite, and Hunton properties.

In the winter of 1912 a winter-road was cut from Swastika to Kirkland Lake, and in December of the same year the first shipment of high-grade gold ore was made from the Tough-Oakes. This was followed by other shipments, and by the fall of 1913 sufficient work had been done to justify more extensive plans. Many of the engineers who inspected the mines during the first stages of development were skeptical of success, the principal objections being the narrow width of the veins at the outcrop and the uncertainty of the ore continuing into the feldspar-porphyry, which, in places, lay under the conglomerate and graywacke. They were also doubtful

as to the values that would be found over a stoping-width of from four to six feet. The most pronounced criticisms were made by German geologists and engineers who visited the mine in 1913. They were visiting Canada as delegates to the twelfth International Congress of Geologists, and were the guests of the Ontario government. The development of the Tough-Oakes mine to a depth of 500 ft. has proved that their fears were groundless.

In 1913 a geological map, to accompany the report on the district by A. G. Burrows and P. E. Hopkins, was issued by the Ontario Department of Mines. This work was of great assistance to the prospectors searching for the most promising areas, and to the operators in carrying out their development.

The rocks of the district are classified as follows:

1. Post-Temiskaming Intrusives: Granite, syenite, feldspar-porphry (intrusive contact), lamprophyre:

2. Temiskaming Series: Quartzite, graywacke, conglomerate, with schistose derivatives.

Unconformity.

3. Keewatin: Greenstone (basalt, andesite, etc.), diabase, quartz-porphry, feldspar-porphry, iron formation, dolomite.

The Keewatin series has the widest distribution, and generally consists of greenstone, either massive or schistose. Where massive, these rocks are of small economic importance, but where sheared and intruded by light-colored acid rocks, they may be significant. The Temiskaming series was laid down on the eroded surface of the Keewatin and later infolded with the Keewatin and eroded, so that it is now highly inclined, and in the townships of Teck and Lebel, where most of the discoveries have been made, probably represents a syncline. The strike of the inclined strata is east, while the schistosity goes north-east. A peculiarity of the conglomerate is the presence of bright blood-red pebbles of jasper.

In the Post-Temiskaming series the feldspar-porphry is the most important. It is generally red and fine grained, intruding the Temiskaming and found both as large masses and as narrow dikes. These dikes and masses trend in a north-easterly direction. Lamprophyre is prominent, but is much older than the other formations and has no connection with the ore deposition. Prospecting has shown a small area extending north-east, about $2\frac{1}{2}$ miles long and 1 mile wide. In this area a number of gold-bearing veins has been found in the conglomerate and in the porphyry of the Temiskaming and Post-Temiskaming series. While the veins are usually found in the porphyry near the contact with other formations, in some cases they are in the conglomerate but pass from that formation into the porphyry. In the sheared conglomerate the veins are well defined, though narrow. In the porphyry there is often a series of quartz stringers and narrow lenses formed along the fracture-zone, producing a deposit of a stock-work type, with quartz veinlets intersecting the porphyry. The main fissures in the conglomerate are sometimes accompanied by subordinate fracturing, thus giving milling-ore over

a width of several feet. The high-grade parts of the vein occur in narrow streaks, generally not more than 10 inches wide. The vein-material consists of white and bluish quartz, which shows the result of repeated fracturing, inclusions of porphyry fragments, and highly silicified country-rock. In some places there is much cementation with calcite. Sulphides, largely iron pyrite, are present, and there is a small amount of copper, lead, and zinc. An interesting feature is the extensive deposition of molybdenite, which usually occurs as a thin film on the fracture-planes. In some of the mines there is considerable free gold, and tellurides are found in almost all the veins. The tellurides present in the ore are altaite, tetradyte, hessite, and probably calaverite. Altaite, the telluride of lead, is the most abundant. It is possible that the molybdenite and altaite may have had some influence upon the enrichment, as experiments have shown that both these minerals will precipitate gold from a chloride solution. Gold tellurides occur in limited amounts, the quantity not being sufficient to contribute much to the value of the ore. Shipments of high-grade ore show a higher proportion of silver than gold, and this is probably due to one of the gold-silver tellurides. The gold is generally free or is associated with the sulphides.

There appears to be a principal zone of fracturing along which the known mines are distributed. Recent development, however, indicates the possibility of at least one other zone, and it is likely that with further work others may be discovered, and the area still further extended. It is a peculiar fact that the shafts of the five principal properties, along a zone more than two miles long, are in a straight line. The ore deposits have been formed at considerable depth and have been exposed by erosion. On the Tough-Oakes and Wright-Hargraves properties there are surface exposures that are indicative of the richness at the lower levels, but on the remaining properties, sufficiently developed to give promise of becoming productive mines, the surface exposures are not as good as have been found at depths of from 100 to 300 ft. This increase of richness in depth is not due in any way to enrichment by descending solutions, but to the fact that Glacial erosion had not, at those points, been carried sufficiently deep to expose the better portion of the veins.

The most easterly development is the Tough-Oakes mine. It is the only mine as yet productive, and is developed to a greater extent than any other in the district. Ore was first discovered in 1912, and from an open-cut on the No. 2 vein, 225 tons of an average grade of \$350 was shipped to the smelter. All of this ore was washed and picked on bumping-tables, the fine and reject being sent to a 5-stamp mill, where about 50% of the gold-content was extracted by amalgamation. The residue was treated in the cyanide-mill and averaged \$14 per ton. Development on the No. 2, as well as on other veins discovered, was so satisfactory that it was decided to build a new mill of about 120 tons per day capacity. The mill was built by the Butters-Johnson

Engineering Co. J. A. Baker, now on the staff of the Dorr Company, was in charge of construction. Work was started in 1914, and in March 1915, just three years after the commencement of mining, the mill was started.

The ore is hoisted from the mine in $1\frac{1}{2}$ -ton skips, which are weighed as they enter the crusher-station. It is crushed in a 20-in. Buchanan crusher, and then passes through a trommel with $1\frac{1}{4}$ -in. holes. The oversize goes to a 12-in. crusher, the product then passing to the fine-ore bin on a 12-in. conveyor-belt. From this bin it is fed to a short conveyor by three plunger-feeders and thence to the ball-mill.

The primary grinding is done in a 6-ft. Hardinge conical ball-mill with a 16-in. barrel. It is driven by a 40-hp. motor, and the counter-shaft has a plamondon clutch. The ore is ground in cyanide solution, the moisture of the mill-pulp averaging 54%. The ball-mill load is 11,000 lb., and consists of 25% of $1\frac{1}{2}$ to 2-in., 40% of 2 to 3-in., and 35% of 3 to 6-in. sizes. In the discharge-end is a steel-wire screen that carries off the oversize, which is returned to the feed-end. The ball-mill product flows to a Dorr duplex classifier, and the under-flow goes direct to the No. 1 thickener. The oversize

goes to a 5 by 20-ft. tube-mill, and the discharge to a second Dorr classifier, thence to another tube-mill for re-grinding. Both of these tube-mills are in closed circuit. Screen analyses show that 85% of the ore is ground to pass 200-mesh. As 85% of the gold is dissolved in the grinding circuit, the pregnant solution from No. 1 thickener flows to a Butters type clarifier containing 12 canvas leaves. The solution is drawn through these leaves with a Goulds vacuum-pump, and is sent to the pregnant-solution tank. The pulp from the No. 1 thickener is transferred with a duplex pump to the No. 1 Dorr agitator 6 by 16 ft. and thence through the others by gravity flow.

From the agitators the pulp is washed in four 28 by 12-ft. Dorr thickeners, and the water is introduced in No. 5. The solution is handled by two Guynnes centrifugal pumps of the four-bearing type. The pregnant solution is drawn from the tank by an Aldrich triplex pump and the zinc-dust emulsion is introduced from a Merrill feeder ahead of the pump. The precipitate is recovered in two 16-frame Merrill filter presses. The zinc-dust consumption is 0.77 lb. per ton of ore treated and 0.16 lb. per ton of solution precipitated. By

MAP SHOWING THE MINING DISTRICTS OF ONTARIO

feeding the minimum amount of zinc-dust the value of the precipitate is increased to \$60 or \$80 per lb. and the weight reduced very much. This also eliminates the necessity for the acid-treatment of the precipitate. The ratio of a ton of solution precipitated to ore treated is five or six to one. The precipitate is dried to about 6%, and charged with fluxes into a No. 295 graphite crucible, and melted in an oil-fired tilting-furnace. The bullion is worth \$14 per ounce. Power for the mill and the plant is at present supplied from a hydro-electric plant at Charlton. This supply, however, is uncertain, and is not sufficient for the needs of this one mine. A new line has been built from Cobalt, 50 miles away, and will supply all the power needed in the district.

During the year 1916 the mill treated 37,263 tons of ore, averaging \$20.10, and 2600 tons of stamp-mill tailing, averaging \$13.52. The total recovery was \$711,000, the production to date being about \$1,380,000. Pregnant solution precipitated per month was 15,655 tons, with an average assay of \$3.57. The barren solution assayed 0.09c. The dry precipitate recovered per month was 867 lb. with an average assay of \$67.16 per pound. The supplies per ton of ore treated during the year were: 1.59 lb. steel balls, 4.29 lb. of pebbles, 1.24 lb. of cyanide, and 3.26 lb. of lime. The cost per ton of ore milled was \$2.43 per ton, made up as follows:

Labor	\$0.54
Supplies	1.15
Power	0.52

The company is working a number of veins, which vary in width from a few inches to six or seven feet. By reason of the narrow width of quartz, at least 85% of the ore milled is made up of feldspar-porphyry, and in some places the vein-quartz does not represent more than 10% of the whole. In places, however, there are swells in the vein that give a stoping-width up to 16 ft. Last year 4153 ft. of development work was done. Ore reserves are estimated at a total value of \$1,000,000. The company has an issued capital of 551,000 shares of \$5 par, and pays dividends of 10% yearly. After the payment of dividends there was a deficit of \$66,000 for the year. This is accountable to the high cost of supplies and the shortage of power, which seriously curtailed operations.

The Sylvanite and the Burnside properties adjoin the Tough-Oakes on the west. Only a small amount of work has been done, but the properties are of considerable merit on account of their location and surface exposures. Unfortunately, however, the Burnside has been lying idle owing to various legal entanglements, and it does not look as if these are likely to be cleared up in the near future. Work on the Sylvanite will be started shortly. When first staked and before the discoveries on the Wright-Hargraves and Tough Oakes, the Burnside property was considered to be of little merit, and the man who grubstaked the locator thought so little of the claims that he refused to put up the money for the first 30 days' work. Three more fortunate individuals who each put up \$10 for a one-twenty-fourth interest subsequently

received \$10,000 each when the property was sold. The Wright-Hargraves, adjoining the Sylvanite on the west, is one of the most promising properties in the district, but, unfortunately, in this case also there was dissension among the owners, and this property lay idle until a few months ago. The difficulties were then adjusted, and a company was formed to take over the various interests. Sufficient capital was obtained, a plant installed, and development work started. There are two known veins on the property, both of which are in the porphyry. From the smaller of the veins a shipment of three tons gave returns of \$400 per ton. The main vein, which in places has a width of 20 ft., has been traced for a distance of 2000 ft. by shafts and stripping. Sufficient work has not been done to show the extent of ore in this length, but the property gives promise of becoming a substantial producer. Near the east shore of Kirkland lake a shaft has been sunk to a depth of 100 ft. The vein at this point is 13 ft. wide, and the average assay in the shaft, which is on the richer portion of the vein, is between \$25 and \$30 per ton. Seven hundred feet away another shaft is being sunk in ore. The company is capitalized at 2,500,000 shares of \$1 each, 700,000 of which remain in the treasury. The next property along the strike of the main zone, and adjoining the Wright-Hargraves on the west, is the Lake Shore. The surface showings were not particularly promising, and the preliminary development would, to most men, have been discouraging. The owner, however, who was one of the original stakers of the Tough-Oakes, continued development until good ore was cut. An ore-shoot, 300 ft. long and averaging over \$15 per ton over a width of 4 ft., has been developed on the 100 and 300-ft. levels. The vein is in the porphyry, near the contact with the conglomerate. Other shoots and other veins will also probably be discovered. The company has ordered part of the equipment for a 50-ton mill. The Teck Hughes lies west of the Lake Shore. Work was done by different interests, and the property was finally acquired by the Buffalo Mining Co. of Cobalt. Several veins have been found and a considerable tonnage of ore developed. At the No. 3 shaft there has been developed 27,000 tons, averaging \$20.63, over a width of 6 ft. This is the only working where the company makes an estimate of the ore reserve, but a number of other important orebodies have been disclosed. In the No. 1 vein a new shoot has been cut; this shows 27 in. averaging \$150, and another shoot intersected by a cross-cut to the same vein shows 20 in. of \$273 ore. On the No. 3 vein the first level shows 5 ft. of \$10.50 ore, and the second level 4½ ft. of \$20 ore. A new shoot, the longest in the mine, has been cut on this vein; it has been developed for a length of 200 ft., and averages \$7 per ton. The mill-feed is expected to run about \$15 per ton. On account of the narrow width of some of the veins the dilution from waste rock is high. A mill has been completed and it is expected to start operating in March. It was ready some time ago, but the company was awaiting the delivery of power from Cobalt. The ore from the mine is delivered to Blake

crushers. The crushed ore is sent to a 5 by 5-ft. ball-mill, the discharge going to a Dorr classifier and a tube-mill, using steel balls, the classifier and the tube-mill being in closed circuit. The continuous counter-current decantation system is used, and the solutions will be changed on the pulp when the treatment is two-thirds over. By the removal of solution high in gold, and the addition of active barren solution, an additional recovery is anticipated. Double-tray thickeners are used, and the pulp is washed on an Oliver filter. The filter is expected to reduce the mechanical cyanide losses as well as to effect an additional recovery. West of the Teck Hughes is the Kirkland Lake mine, which is under option to the Beaver Mining Co. It is being developed energetically, and a shaft is now down 500 ft., with a level at each hundred feet. On the surface there was only a small exposure of high-grade ore, and nothing of much importance was developed until a point below the 200-ft. level was reached. On the 300-ft. level three high-grade veins were found, while the porphyry between was mineralized and intersected with quartz stringers, which assay well. It is stated that on the 300-ft. level there is, in one place, a width of 42 ft. that will average \$9.50. On the 400-ft. level the development to date gives an average assay of \$18 over a width of from five to six feet. Some driving has been done on the different levels, but the company has been hampered by small compressor-capacity. A new plant has, however, been ordered. It is estimated that over \$500,000 worth of ore has been developed to date. In the latter part of February the company made the first payment of \$75,000 on the property.

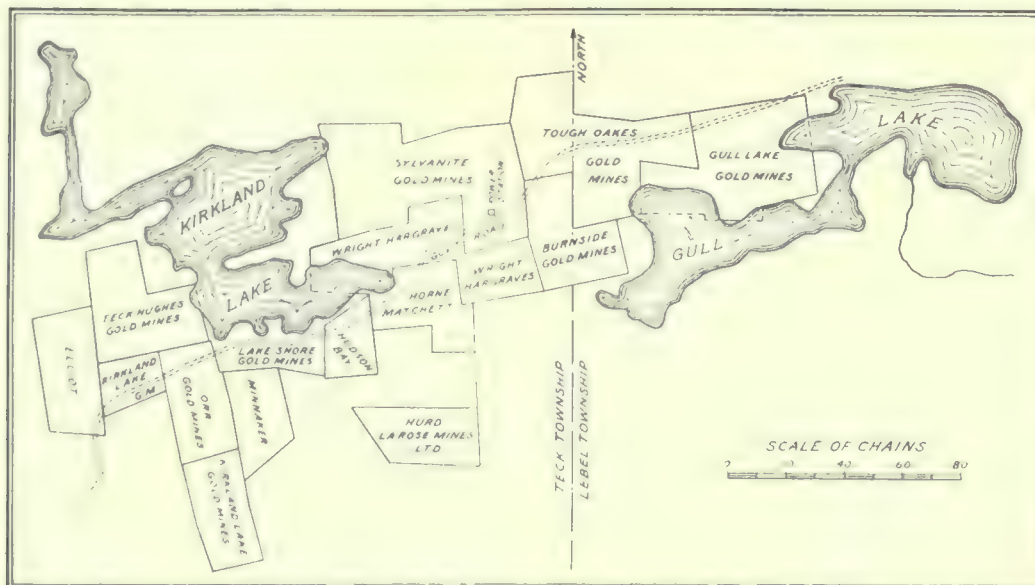

The success attending the development of the Kirkland Lake mine has resulted in operations being started on properties still farther west, and it is possible that the present westerly limit of the known mineralized area will be extended. Several other properties south of the main zone are now being worked, and while some discoveries that may be of importance have been made, on

none of the properties has sufficient work been done to justify an opinion as to their real value. Very little prospecting has been done outside of the main zone, but

STOPE IN THE TOUGH-OAKES MINE

in view of the favorable geological indications, and the satisfactory development of most of the properties, it is a fair assumption that other mines will be discovered.

THE PRINCIPAL MINING PROPERTIES OF KIRKLAND LAKE

It can be definitely stated, however, that nowhere in Canada is there a gold-mining district where such good results have been obtained for such a small amount of development work.

The Government has built a good wagon-road from the railway to the mines, and the settlement is excellently provided in the matter of telephone, telegraph, and train service. One can step out of a Pullman at Swastika and in less than an hour's drive arrive at the Tough-Oakes mine, which is farthest from the railroad of any of the operating properties. The mining industry of Ontario is fortunate in the service that is rendered by the Provincial Geologists. Their reports on the different mining districts, which are published as soon as, and often before, anything of interest is discovered, are comprehensive and extremely valuable as an aid to prospecting, exploration, and development. This is nowhere more evident than at Kirkland Lake, and acknowledgments are due to them for the geological information contained in this article.

No Oil Sands in Mexico

*Few people know the geological structure of the Mexican oil-fields. No one in the world today knows it perfectly. Nothing yet uncovered in the United States resembles the underground formation in Mexico. In California they pump from well-defined areas of oil-sands two to three thousand feet deep. The porosity of oil sand is about 14%, and those wells do not average 200 barrels per day. But there are no oil sands in Mexico. About 2000 ft. below the level of the sea the drill strikes the bed of ancient oceans and from coral reefs with 60% porosity spurt the greatest oil wells in the world. No pipe-line yet constructed has been able to receive the full measure of one of these gushers. South of Cerro Azul is the great Potrero oil well of the Mexican Eagle or English company. It gives the entire 40,000 bbl. per day that this company can export with its existing shipping facilities, but this is not half of its capacity. Lord Cowdray is giving his whole time to his country at the head of the British aviation department, so essential on land and sea in winning the War, and his pipe-lines and refineries work automatically on the Mexican coast. When the War is over this field may compete for his great organization and engineering talent. To the north, near the terminus of the Mexican Petroleum Co.'s railroad at San Gerónimo, on the borders of the Tamiahua lagoon, still rises a cloud of steam from the ruins of the famous well of Dos Bocas. Here in 1909 unexpectedly came in the world's greatest gusher. Through an 8-in. casing shot a column into the air 1500 ft. high by actual theodolite measurement, belching 300,000,000 bbl. of liquid per day. How much of it was oil nobody could say. The torrential flood reached the boiler fires and soon, in place of an 8-in. casing, was a heavily seething mass, 100 acres in extent.

Selective Flotation Applied to Zinc Blende

Experiments on selective flotation, made by J. M. Callow and his staff, have developed interesting features that have been put into practical use at the Utah Apex mill at Bingham, Utah, and at the Magma Copper Co.'s plant at Superior, Arizona. The method employed in the latter mill has been outlined in a paper, 'Notes on Flotation—1916,' by Mr. Callow, published in the transactions of the American Institute of Mining Engineers in February. The zinc is raised in preference to the pyrite by using 34° B. fuel-oil in combination with No. 17 oil of the General Naval Stores, and adding 0.1 lb. copper sulphate per ton of ore treated. The function of the copper sulphate is not understood, but it has been suggested that it may act as an electrolyte, although sulphuric acid, which had formerly been used, had failed to yield zinc concentrate with a low insoluble content. Part of the galena in the ore was removed before flotation by table-concentration, and part of it was floated with the zinc, from which it was separated afterward by tabling the flotation-concentrate. The mill-feed at the Magma copper plant averages about 185 tons per diem, and the cost of the flotation alone is about 34c. per ton of crude ore, exclusive of filter-pressing the concentrate, which adds about 7c. per ton. The total milling cost is about \$1.10 per ton, in which is included 22c. for sorting. No general expense or overhead charges enter into the foregoing figures.

At the Utah Apex plant an entirely different method is applied. The ore treated contains zinc-blende associated with a preponderating amount of pyrite. The oil-mixture employed consists of 33% No. B-14 wood-tar (U. S. Naval Stores Co.), 67% No. 150 pine-oil (Pensacola Tar & Turpentine Co.), this mixture being added at the rate of 2 lb. per ton of ore. Sulphuric acid in the proportion of 1 lb. and salt-cake 100 lb. per ton of ore are also introduced with the pulp flowing into the Callow cells. The result is to lift out the zinc-blende quite free from pyrite. A curious circumstance is that by increasing the amount of salt-cake to 150 lb. per ton of ore, the effect is exactly reversed, the pyrite being floated and the zinc left in the residue. The impossibility of predicting the adaptability of a method to any particular ore from a consideration of superficial likeness in character is brought out forcibly by the failure of the Magma mill-pulp to respond to a like treatment. Each ore presents its own peculiar problems, and the possibilities of making combinations of flotative agents and assistants to bring about physical conditions favorable for floating different minerals seem to be infinite.

SHALES AND SANDSTONES occasionally carry gold and silver in payable quantity. The silver-bearing shales and sandstones of Silver Reef, Utah, and the gold-bearing sandstone of Lawrence county, South Dakota, are among the examples. Extensive auriferous sandstone beds have been found in Central Africa.

Beneficial Effect of Grinding With Steel Balls for Flotation

By VICTOR ZACHERT

Ore as extracted from the mine contains, with few exceptions, a certain percentage of comminuted material generally termed slime, in which also exist the metaliferous constituents of the ore. This comminuted material is the result of nature's disintegration, and in this instance to designate the slime correctly an appropriate term would be 'natural,' instead of 'primary.' Primary slime may be misinterpreted as the slime produced artificially at some stage in the process of ore reduction. While natural slime is detrimental to flotation treatment, artificial slime is not so. Experience with many ores that have been subjected to flotation treatment has shown that the best results are obtained when the mineral has been freshly fractured by crushing of the ore. To explain this phenomenon the influence and effects produced by the presence of all the elements, both physically and chemically, must be considered. When a solid body is made to change its physical characteristics by altering its structure or position, a certain amount of resistance is offered, resulting in the evolution of heat. In the case of an ore from which the enveloped metalliferous constituents are to be liberated, the practical methods available are to crush the ore either by compression or attrition. In both bases resistance must be overcome and heat produced. The rise of temperature has been often verified when grinding ore in a tube-mill for cyanidation. The heat is so intense on the lines of rupture of the particle that the mineral is subjected to chemical changes, resulting in the decomposition of the minerals (including the sulphides). The chemical change, however, does not extend throughout the entire particle, but sufficient superficial change has been effected to alter its characteristics owing to the formation of gaseous films, and an oil, adhering more readily to the mineral enveloped in such a film, will select it in preference to one enclosed by a water-film. The reason why minerals in the natural slime are refractory to flotation treatment is that the gaseous films developed during disintegration of the ore in nature have long ago vanished, though the necessary condition may be restored by friction with coarse ore. "While the re-ground oversize yielded remarkably lean tailings," states Rudolf Gahl,* "the product containing the primary slime could not be treated advantageously by flotation. We were almost on the point of concluding that in order to get the best results, a separation of the primary slime should be made in the large mill, and flotation should not be relied upon entirely for the treatment of the slime. Before finally deciding this, however,

additional laboratory experiments were made to ascertain the influence of the primary slime on flotation. These tests established one fact quite well, which is, that when refractory slime is mixed with a sufficient quantity of coarse ore ground to the necessary fineness, in other words, when the percentage of primary slime in the flotation-feed is kept low, the slime loses its refractory character."

The natural slime in the ore is a point that should not be indifferently regarded by the flotation metallurgist, and its character, quantity, and influence upon the flotation results should be carefully observed and considered. One may be laboring on the solution of a flotation treatment-problem, and at the same time be entirely unaware that the impediments to success lie in the deleterious action of the natural slime. In determining the adaptability of an ore to the flotation process, the sample of ore that is to be subjected to test should receive a preliminary water-wash to remove the natural slime, and the latter should be investigated independently of the coarse portion of the sample. In many instances, especially when the valuable constituents of the ore predominate in the natural slime (or the slime of accumulated tailings, which may also be classified as natural slime) a separate treatment of the two products may be necessary.

As regards artificial slime, the nature and composition of the grinding medium also has an influence upon the final flotation results, a fact which has been practically demonstrated at the Inspiration mill, where steel balls have been substituted for flint pebbles in the grinding-mill, immediately giving an improvement in the extraction by flotation. On this matter Rudolf Gahl† says, "While these tests were in progress, we made another useful discovery. In our tests on the most economical way of reducing the ore to the fineness necessary for flotation, we had, among other machines, a ball-mill in competition with pebble-mills. In the ball-mill, steel balls performed the duty that in pebble-mills was done by flint pebbles. For awhile, the ball-mill discharge was treated on one flotation machine, while the pebble-mill discharge was treated on a group of others. While this flow-sheet was being followed we thought we noted that a flotation machine treating the ball-mill product showed the influence of the primary slime to a less extent than the flotation machine treating the pebble-mill product. In a discussion with Dr. Ricketts and Mr. Mills, the question was raised as to whether the iron introduced in the

*'History of the Flotation Process of Inspiration.' By Rudolf Gahl. M. & S. P., Sept. 30, 1916.

†'Notes on Flotation.' By Rudolf Gahl. M. & S. P., Sept. 23, 1916.

pulp by the attrition of the balls might not have something to do with the fact. The question was accordingly made the subject of some laboratory experiments. The results of the experiments proved conclusively that the iron had a beneficial influence on flotation in counter-acting the harmful effect of the primary slime. This discovery was one of the inducements for installing ball-mills in the big concentrator plant, while originally pebble-mills had been considered for this purpose. We have not yet reached a point where we can safely give the reason for the action of the iron introduced into the pulp."

So far no satisfactory explanation has been advanced to account for this beneficial effect on the extraction by flotation in changing from pebbles to steel balls. An effort to determine the possible cause of this improvement has led to the conviction that magnetism plays an important function in the matter. When movement is imparted to two steel bodies, so that friction is developed between them, they acquire magnetic properties. This may be experimentally demonstrated by drilling a hole with a steel drill in a piece of soft steel. After a few turns of the drill, an examination will show that small fragments of the steel borings adhere to its end, indicating that the drill has acquired magnetic properties. Another experiment to demonstrate magnetization by friction of two steel bodies, but to a less extent, is by forcibly stroking a needle several times over the surface of a good steel file. The needle will then possess magnetic properties. In crushing ore by means of steel balls, some of the steel is scoured off the balls by abrasion, and forced into the pores of the minerals, giving the minerals magnetic properties, resulting in attracting one to another and collecting them into a mass. This mass is further attracted by the magnetized steel balls. It is much easier to incorporate oil with the mineral when it exists in the form of an agglomerated mass than when the mineral is disseminated through the pulp in a state of minute subdivision.

A requisite in the flotation process is the proper oiling of the mineral particles. To accomplish this demands care on the part of the flotation-metallurgist. In the majority of instances where flotation is practised, oiling of the mineral is done at some period following fine grinding and prior to or during flotation. The most effective and reliable method by which this can be done is to incorporate the oil with the metalliferous matter by grinding the ore in the presence of oil or of an oil-bearing substance; however, this procedure is effective only when the metalliferous matter is not in too fine a state of subdivision. It may and often does occur that during grinding the mineral which has received proper oiling will again lose its coating before approaching the discharge-end of the grinding-mill. My investigation has shown that magnetism is of extreme importance in causing the mineral of the natural slime to yield readily to flotation. Another experiment was made to determine if the results could be improved by increasing the magnetic force within the grinding zone; therefore the steel

balls were magnetized by means of an electro-magnet and then introduced into the grinding-mill with ore, water, and a small quantity of oil. Immediately the beneficial effect of the increased magnetic properties could be observed by the discoloration of the pulp after grinding. The ore selected for this experiment was composed of chalcocite in a white quartz gangue, all of which passed a 40-mesh screen, and the pulp in appearance resembled ground coal-dust. This sample, when reduced in a small ball-mill provided with magnetized steel balls, and ground to pass a 60-mesh screen, was seen to be composed of snow-white quartz mixed with occasional specks of agglomerated particles of oiled chalcocite, averaging in size from minus 60 to plus 100-mesh. To determine the fineness of these agglomerated particles of chalcocite a portion was washed in gasoline to remove the oil. After filtering and drying, 80% of it passed a 200-mesh screen. On examining this fine material it presented a moss-like appearance, indicating that the minute particles of the chalcocite still retained magnetic properties, and the moss-like appearance was due to agglomeration from the magnetic attraction which each particle of mineral exerted individually. Means were not available for making quantitative determinations for the purpose of computing the percentage of extraction. The main object of the experiment was to study the influence and effects produced by grinding the ore under conditions to induce magnetism. In conclusion, I may state that the discovery and corroboration by experiment proves that magnetism performs an important function in the preliminary preparation of ore for flotation-treatment, and leads to an explanation of the phenomenon causing a beneficial influence in flotation when grinding the ore in a ball-mill.

CHROMIUM, MOLYBDENUM, TUNGSTEN, AND URANIUM are closely affiliated chemically and all form acid tri-oxides like that of sulphur, SO_3 . Chromium forms also the stable basic oxide Cr_2O_3 which resembles ferric oxide in its properties. It forms in silicate environment and is a constituent of igneous rocks. In sulphide deposits chromium is dissolved and re-precipitated, but so far as any evidence is available it is not very migratory. Molybdenum and tungsten oxidize slowly to secondary minerals which generally remain near the parent primary minerals. Molybdenite is not dissolved in hydrochloric acid nor in sulphuric acid, nor, at the end of one month, in the presence of ferric salts. Tungsten forms tungstic acid, $\text{H}_2\text{WO}_4 \cdot \text{H}_2\text{O}$. This is somewhat soluble in water. In moist climates, it could be leached out of deposits which were exposed long enough, but the reaction is exceedingly slow. Tungsten minerals are so insoluble that they commonly form placers. Both molybdenum and tungsten are classed with the non-migratory metals. Uranium, on the other hand, is carried in underground waters and doubtless forms secondary deposits of considerable importance. The deposits of south-western Colorado, as already stated, are believed to be re-concentrations by ground-water near the present surface.

National Engineering Societies and National Service

The administrative organization for the conduct of the War is set forth on the accompanying diagram, showing the mechanism for the contributions to be made by the national engineering societies. This diagrammatic expression of the co-ordination of the engineering talent of the country was prepared by Philip N. Moore and Bradley Stoughton to show engineers through what channels their services might be made available. With the exception of the direct contribution to military and naval operation as trained specialists serving in the Officers' Reserve Corps, all civilian technical effort is finally co-ordinated for Government service through the Council of National Defense, which stands next to the President, and serves

tulates directly with the Council of National Defense on all matters of general engineering, and it calls upon the individual members and resources of the National Engineering Societies for service in connection with general engineering matters, not including inventions which belong in the field of the Naval Consulting Board, nor research which is looked after by the National Research Council.

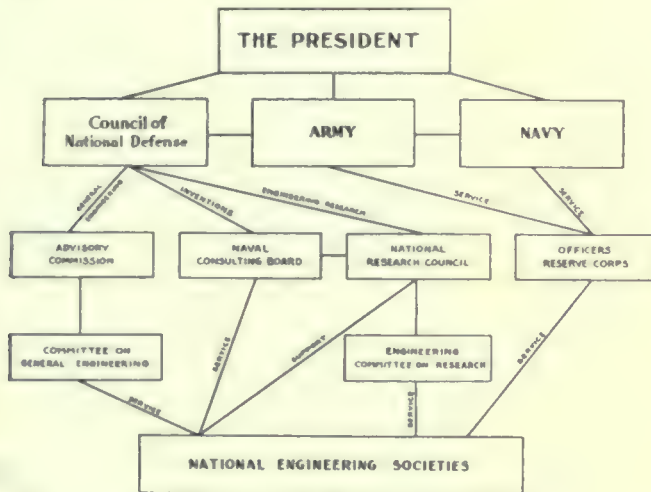

THE NAVAL CONSULTING BOARD was appointed by the President of the United States upon nominations made by the National Engineering Societies and others. The American Institute of Mining Engineers is represented on that Board by W. L. Saunders, who serves as its chairman, and by Benjamin B. Thayer. Six other members of the A. I. M. E. are also members of the Naval Consulting Board. This Board articulates directly with the Council of National Defense and advises upon all questions having to do with the investigation and development of inventions for the use of the Army and Navy Departments and any other branch of the National service; it does not, however, articulate directly with the Government Departments, but reports to the Council of National Defense.

THE NATIONAL RESEARCH COUNCIL was formed by the National Academy of Sciences at the request of President Wilson. The National Academy of Sciences was formed during the Civil War for the purpose of assisting the Government. The National Research Council's organization and operating expenses, but not its research expenses, are paid by the Engineering Foundation, which is a creation of the United Engineering Society. The National Research Council co-operates with the Naval Consulting Board and the Council of National Defense in all matters having to do with research, but not with inventions nor with general engineering.

The American Institute of Mining Engineers is represented on the Engineering Committee of the National Research Council by Pope Yeatman and Albert Sauveur. Other members of the A. I. M. E. are also on this committee.

THE OFFICERS' RESERVE CORPS was developed by a Joint Conference Committee of the national engineering societies and became law by Act of Congress in July, 1916. Application-forms for a commission in the Officers' Reserve Corps, Department of Engineers, can be obtained from the War Department, Washington, D. C., or from the secretary of the American Institute of Mining Engineers.

It is desirable to obviate duplication of effort. Multiplicity of organizations throughout the country for patriotic service is a feature of the first impulse before ripper experience shall have shown how they should be co-

WAR-ORGANIZATION OF ENGINEERING SOCIETIES

as his right hand in maintaining and utilizing the industrial competency of the Nation in this hour of crisis. The Council of National Defense is composed of four Cabinet Officers assisted by eight civilians, namely, Daniel Willard, chairman, president of the Baltimore & Ohio Railroad, Howard E. Coffin, an engineer of the highest ability and vice-president of the Hudson Motor Co., Dr. Hollis Godfrey of the Drexel Institute., Samuel Gompers of the American Federation of Labor, Julius Rosenwald of Sears, Roebuck & Co., Bernard H. Baruch, a banker, Dr. Franklin H. Martin, and Grosvenor B. Clarkson, secretary to the Board.

The Advisory Commission of the Council of National Defense is composed of civilians who are chairmen of committees on Engineering, Finance, Agriculture, etc. Dr. Hollis Godfrey is a member also of the Advisory Commission and chairman of its Engineering Committee. The President and Secretary of the American Institute of Mining Engineers likewise have been appointed members of the Engineering Committee. This Committee ar-

ordinated so as not to overlap and interfere. The State Geologists and the U. S. Geological Survey, for example, should arrange for a division of work in giving information concerning probable new sources of metals and industrial minerals, so that each may do that for which it is best fitted. Several of the States, among which is California, have organized their own Councils of Defense, appointed by the Governors. An organization of this kind is practically certain to expend useless effort, unless its work be co-ordinated with the federal or national bureaus and committees. This is apparent to the members of these State Councils, and so far their efforts have been directed chiefly toward taking a census of resources, physical and other, which will necessarily be helpful to the Council of National Defense. The political motive

back of the laws creating these local organizations seems to have developed out of the historic insistence upon State's rights. It is not to be condemned since it shows that the democratic spirit that is unwilling to relinquish too much of its authority to centralized control is still vital. It is well enough to keep the ideals of independent self-government in evidence; meanwhile it is to be hoped that the conception of responsibility for actual defense, as a movement apart from the Federal forces, be not taken too seriously. Local direction of production in harmony with the national requisitions, coupled with the maintenance of an effective rural police having wider jurisdiction than county officers, would render the State Councils a most useful aid to the general endeavor of national-committee work.

Hybinette Electrolytic Nickel-Refining Method

*The bessemerized copper-nickel matte, containing about 47% nickel, 33% copper, and 20% sulphur, with usually less than 0.4% iron, is granulated and roasted. It is then leached with a 10% solution of sulphuric acid to dissolve the major part of the copper. The residue is melted and cast into anodes, which contain about 65% nickel and from 3 to 8% sulphur, with traces of copper and iron. The electrolyte used for the nickel carries 45 grammes nickel, and from 3 to 5 milligrammes of copper per litre, and is supplied by rubber tubes to the cathode diaphragms. After circulation it has from 2 to 3 gm. copper per litre, and is passed over waste anodes which deposit the copper and re-supply nickel to the solution. The action of the anodes is analogous to that of pig-iron in precipitating cement-copper, except that the copper is deposited by nickel instead of by iron. The amount of waste-anode resulting after electro-deposition of the nickel is about 40% of the original weight, and is sufficient for rejuvenating the exhausted solutions from the nickel vats. The solutions never have to be rejected as they are sufficiently purified by the cementation. Waste fragments, after the cement-copper has been brushed off, are crushed, roasted, leached with 10% sulphuric acid to dissolve more copper, and the residues are melted into anodes and re-electrolyzed. The anodes for the nickel department are enclosed in special canvas bags, stated to last 18 months. Paper diaphragms supported by common canvas at times have been substituted and have lasted 12 months. The cathodes are of iron treated with a wash of powdered graphite. The nickel deposits on both sides of the cathode-plate. These plates are arranged in parallel. The voltage is from 3 to 4 v. per tank, according to current-density, which varies from 8 to 10 amp. per square foot. The large tanks contain 20 cathodes and 21 anodes, and the smaller tanks 10 to 14 cathodes and 11 to 15 anodes. The deposition of the nickel takes about 15 days, and the sheets stripped from the cathodes weigh

20 to 30 lb. each. They are about $\frac{1}{8}$ in. thick, and have the usual corrugated warty appearance, but the stalactitic growths are dense and give no trouble through short-circuiting. The sheets are washed in weak sulphuric acid to remove basic salts, are dried, and cut into 2 to 3-in. strips for market. The metal is guaranteed 99% pure, with usually no more than 0.03% copper. The precious metals accumulate in the anode-slime, which is re-melted into anodes and separately electrolyzed, the final slime being caked, dried, and sold for its precious-metal content. The copper is separately deposited, but on copper sheets and without encasing the insoluble lead-anodes in bags. The current-density is about 10 amp. per square foot at 2 v., and there are usually 9 cathodes and 8 anodes per tank. The high-tension current is first stepped down to 220 v. (alt. cur.) and then converted to direct-current at a voltage between 160 to 170 v. This process is carried out in Norway on matte from Evje and Ringerike, where power costs about \$13.50 per hp. yr. It will be applied at the works of the British America Nickel Corporation, Ltd., at the Murray mine, near Sudbury, Ontario. The American patents covering the process are No. 805,555, 805,969, 1,128,313, and 1,128,316, all of which have been assigned to the National Trust Co., Ltd. of Toronto.

ZINC-EXTRACTION, according to a method being exploited by the Minerals Products, Ltd., is reported as follows: The ore or concentrate is roasted to a low sulphur-tenor, converting the metals into oxides; it is then triturated and treated with a boiling solution of ferrous sulphate which dissolves the zinc as per the reaction:

The operation is accomplished at normal temperature and pressure and without aeration. It is said to be specially applicable to zinc ores containing lead. The manner of dealing with the problem of filtration is not stated. This would seem to offer difficulty in the case of a gelatinous precipitate such as ferrous hydrate.

MANGANESE is in such sharp demand that a contract for Brazilian ore has just been closed at \$1 per unit. Ferro-manganese has soared to \$450 per ton.

*Abstract: Report of Ontario Royal Nickel Commission, 1917.

Lead Production in 1916

Statistics of lead produced in the United States, compiled by C. E. Siebenthal for the U. S. Geological Survey, show an output of 571,134 short tons of primary refined metal, being an increase of 3.8% over the amount reported for 1915. The total lead, both smelted and refined, amounted to 615,127 tons, of which 596,221 tons came from domestic ores. Missouri leads with a production of 218,253 tons of lead, followed closely by Idaho with 170,059, while Utah stands third with 111,789. The next highest producer is Colorado, which turned out 33,046 tons. Imported ores and bullion added 18,906

height as producer from which that country has fallen is better revealed by comparison with her exports to the United States in 1910, which amounted to 203,290,307 lb., which makes the present output only 23% of what it had attained under better political conditions.

Production of Spelter in 1916

The significant feature of zinc production within the year has been the rapid development of electrolytic reduction. Starting from the experimental stage in 1915 it had reached the point where it was yielding at the rate of 40,000 tons, or 6% of the total spelter of the

Average weekly price of lead at New York and London, 1914-1916.

tons to the total production. The recovery of lead from zinc residues reached the important figure of 5478 tons. The following tabulated statement reveals the situation as to stocks of the metal, and movements to and from the country:

REFINED PRIMARY LEAD				
Supply:	1914	1915	1916	
Stock in bonded warehouses Jan. 1.	5,310	7,668	12,169	
Imports—				
For consumption	7,386	9,680	12,771	
For warehouse	20,952	41,816	22,559	
Increase by liquidation.....		2,250	5,642	
Production from domestic ores....	512,794	507,026	552,228	
Total supply.....	546,442	568,440	605,369	
Withdrawn:				
Exports of foreign lead—				
From warehouse	21,545	38,618	9,880	
In manufactures, with benefit of drawback	9,399	3,983	5,171	
Exports of domestic lead.....	58,722	87,306	100,565	
Decrease by liquidation.....	56			
Stock in bonded warehouse Dec. 1.	7,668	12,169	12,369	
Total withdrawn	97,390	142,076	127,985	
Available for consumption	449,052	426,364	477,384	

The imports of lead show the effects of the current wars and revolutions in a striking manner. South America has practically held its own, sending us a total of 6,235,758 lb.; Canada has leaped from 338,569 lb. in 1913 to 12,606,216 in 1916; and Mexico has declined from 95,693,439 lb. in 1913 to 48,395,670 in 1916, but the great

country, by the end of 1916, and the plants now building will have a capacity of 85,000 tons per annum. The most notable of the electrolytic plants is that of the Anaconda Copper Mining Co., which has reached an output of 100 tons per day, and will soon be ready to turn out double that amount. The statistics compiled by C. E. Siebenthal of the U. S. Geological Survey, accompanied by a chart showing diagrammatically the average prices and production for the year, which we reproduce on another page, reveal a total output of primary spelter of 667,456 short tons in 1916, being an increase of 37% over the previous year, or 92% above the production in 1913. The marked changes in our world relations brought about by the War, which will undoubtedly leave a profound impress upon the metallurgic activities of this country in the future, is shown by the importation last year of 385,964 tons of zinc ore containing 148,147 tons of the metal, whereas in 1914 the importation of zinc in ore amounted to no more than 12,132 tons. Of the imports, Australia furnished ore and concentrate having a zinc-content of 41,958 tons. The total number of retorts under heat at the end of 1916 was 219,418, as against 156,568 in the preceding year. The smelting capacity remained nearly stationary in Illinois, Kansas, and Missouri, the great increase being in Oklahoma and Pennsylvania. In Colorado, Arkansas, and West Virginia there was an actual decrease. The average annual capacity of a retort being about 4 tons, the existing potential output from retort-

smelters would be 875,000 tons per year. Over 11,000 retorts were idle on December 31, while 13 new smelters were completed and construction on two more was started. Mr. Siebenthal calls attention to the rapidity and secrecy with which gas-fired smelters have been built in the South-west. In 1915 the average quoted price for prime Western spelter at St. Louis was 14.2c., while lower prices prevailed for future deliveries. The average quoted price in 1916 was 13.6c., and the average

price received for spelter of all qualities, prime Western, brass-special, and high-grade, was 13.4c. The smaller difference between the quoted price for immediate delivery and the price received during the year was due apparently to an increase in domestic consumption, to a decrease in sales for future delivery, and to the production of a larger proportion of high-grade spelter.

Statistics of production of secondary zinc have not been fully available, due largely to the extraordinary

demand for scrap, dross, brass-melters' flue-dust, and other materials of this kind by collateral industries. Secondary spelter, re-distilled, aggregated 29,663 tons.

CONSUMPTION OF PRIMARY SPELTER

(Tons of 2000 lb.)

Supply:

Stock, January 1:	1913	1914	1915	1916
In bonded warehouses..	48	111	32
At smelters	4,474	40,659	19,984	14,221

Production:

From domestic ore.....	337,252	343,418	458,135	563,451
From foreign ore.....	9,424	9,631	31,384	104,005
Imports	6,100	880	904	684

Total available.....	357,298	394,588	510,518	682,393
----------------------	---------	---------	---------	---------

Withdrawn:

Exports, foreign, from warehouse	6,027	5,580	12,776	43,230
--	-------	-------	--------	--------

Exports, foreign, under drawback	7,459	4,981	255
--	-------	-------	-----	-------

-----------------------	--------	--------	---------	---------

Apparent consumption..	295,370	299,125	365,438	458,428
------------------------	---------	---------	---------	---------

The table on preceding page shows the consumption of primary spelter and the domestic and foreign movement of the metal, whereby the apparent domestic consumption is seen to be 458,428 tons.

St. Louis Meeting of the A. I. M. E.

In extending an invitation to the American Institute of Mining Engineers to meet in St. Louis next October, the St. Louis Section properly calls attention to the extraordinary mining and metallurgical attractions in the vicinity of that city, as follows:

"Perhaps few know that the South-east Missouri district, about 80 miles south of St. Louis, and to which a special trip is planned, is the largest lead district in the world. In 1913 the production of the world was 1,270,000 tons, the last world figures obtainable, and in that same year the production of the United States was 412,000 tons, of which south-eastern Missouri contributed 133,000 tons. In 1916 the production of the United States was over 600,000 tons, and that of south-eastern Missouri 184,000 tons, being 32% of the total. The ore occurs not in veins, but disseminated through a great bed of magnesian limestone, more than 400 ft. thick in places, and as mined carries an average of about 3% lead. It has taken nearly a generation to perfect the concentrating plants, and the managers do not consider them perfect yet. The ore is crushed and cleaned until the concentrate will run about 70% lead. Some interesting developments in flotation are in progress, and nearly one-tenth of the clean ore shipped to the smelters is produced by that method. The concentrate is smelted at plants situated at Herculaneum, Alton, and Collinsville, with a combined capacity of 250,000 tons of lead per

annum. These smelters will all be visited on the occasion of the meeting. The uses of the lead are also interesting. Just now its tremendous importance as a war material overshadows the fact that probably half the product goes into the form of white lead and other kinds of paint. Much is used as anti-friction metal, and as pipe and sheet."

Electrolytic Zinc

*The complex-ore question has been an unsolved metallurgical problem for a generation. It is now practically solved. What under old conditions was waste has suddenly become valuable. Even if only 80% of the zinc in complex ores can be recovered successfully by the electrolytic process in its present state of development, the removal of this large percentage of a deleterious element from a complex ore will simplify the extraction of the remaining more valuable elements. Western metallurgists now estimate that they can treat the so-called complex ores by the new method, crediting to the process the value from the sale of silver, gold, copper, and lead, and producing zinc at a price that will compete with the retort-process under normal conditions. Even had the War not broken out when it did the electrolytic zinc process would still have been developed. The directors of the Anaconda Copper Mining Co. were so impressed with this belief that they authorized a series of experiments at large cost. These were concluded under the direction of Frederick Laist, and they constructed a plant that produced 10 tons of zinc per day and later increased this to a capacity of 35 tons. They then decided to build a modern plant close to the source of power, as this is the principal item of cost in the process, erecting the largest electrolytic zinc refinery in the world at Great Falls, Montana. The plant, as designed, will consist of five units. Late in December three units were in operation, producing 95 tons of metal per diem, assaying 99.92% zinc. The completed plant will have a capacity of 160 to 175 tons of zinc daily. During the experiments in the test-plant at Anaconda the process originally proposed by Laist and Frick was much simplified, consisting essentially of the following steps: first careful roasting of the concentrate at temperatures not exceeding 730° C.; dissolving the zinc, together with a little iron, by spent electrolyte in Pachuca tanks. A small amount of manganese di-oxide is added to oxidize the iron, which is then precipitated by powdered limestone, bringing down any arsenic or antimony that may be in solution. This is leached through Oliver filters, and the residue is sent to the blast-furnace, while the filtrate, containing only zinc sulphate, with a little cadmium and copper, is treated with zinc-dust and again filtered, the filtrate being the pure zinc-sulphate solution which is sent to the tank-room. The anodes are of pure lead and the cathodes of pure aluminum. Deposition goes on for 48 hours only, when the zinc is stripped from the cathode-sheets and melted into slabs.

*Abstract of paper by E. P. Mathewson, Bull. Can. Min. Inst.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

CRIPPLE CREEK, COLORADO

LARGE PRODUCTION BY LEADING MINES MAINTAINED.—NEW DEVELOPMENT AND INSTALLATIONS PROPOSED.

The production of the Cripple Creek mining district, for the month of April, amounted to 64,598 tons, with an average value of \$14.55 per ton and a gross bullion value of \$940,048. This ore was treated at the several plants as follows:

Plant and location	Tons treated	Average value	Gross value
Golden Cycle Mining & Reduction Co., Colorado City....	30,000	\$20.00	\$600,000.00
Portland G. M. Co., Colorado Springs	9,158	18.09	165,648.22
Portland G. M. Co., Victor mill	21,000	1.96	31,160.00
Isabella Mines Co., Cripple Creek district	1,540	3.00	4,620.00
Worcester-Rubie, Bull Hill ...	400	2.80	1,120.00
Smelters, Pueblo and Denver..	2,500	55.00	137,500.00
Total	64,598	\$14.55	\$940,048.22

Dividends of record amounting to \$300,000 were distributed during the month of April by Cripple Creek mining companies. The dividends are as follows:

	Per share, cents	Dividend
Cresson Consolidated G. M. & M. Co.....	10	\$120,000
(Regular monthly dividend)		
Vindicator Consolidated G. M. Co.....	3	45,000
(Quarterly)		
Golden Cycle M. & R. Co.....	3	45,000
(Monthly)		
Portland Gold Mining Co.....	3	90,000
(Quarterly)		

The dividends do not include those of the close corporations and leasing companies and partnerships. The Cresson Consolidated G. M. & M. Co. has paid dividends totaling \$600,000 to date for the present year, and the Golden Cycle M. & M. Co. has paid stockholders \$185,000 this year.

The Cripple Creek deep drainage tunnel was advanced 175 ft. during the month of April, only one shift being employed. The tunnel will shortly pass through the Little Edith claim of the Queen Gold Mining Co. (a close corporation controlled by J. T. Milliken, of St. Louis) into the property of the United Gold Mines Co., and thence into the Portland Gold Mining Co.'s property. A flow of 9000 gal. per minute is recorded at this time.

The Portland Gold Mining Co. is operating three mills. The Colorado Springs mill is treating 9158 tons monthly; the Victor mill is treating 21,000 tons. The second unit of 250 tons will be in operation at the Independence mill of this company by May 10. The 500-ft. level of the No. 1 shaft has been thrown open to lessee operators, the available ground being quickly taken and some of the leasees already are producing.

A powerful hoist and boiler have been installed at the Rose Nicol shaft of the Rose Nicol Gold Mining Co., under lease to the Camp Bird M. M. & D. Co. Deep development is progressing from the 1000-ft. level of the Portland No. 2 shaft and it should be in Rose Nicol property by the middle of May.

New machinery is being installed at the Wild Horse shaft

of the United Gold Mines Co. preparatory to sinking from the 1275-ft. level to a total depth of 1600 ft. The Deadwood group of this company is being developed at depth by a lateral from the 1000-ft. level of the Lee shaft of the Isabella Mines Company.

The Acacia Gold Mining Co. is sinking the South Burns shaft. Ten cars of ore from that shaft and two from the North Burns shaft were shipped during April.

The controlling interest in the Free Coinage Gold Mining Co. was recently sold to Chicago parties and the new company, now in course of formation, expects to resume operations on this Bull Hill property about May 15, according to Denver advices.

The Auraria G. M. Co.'s Forest Queen mine is under lease to Edwin Gaylord, who is breaking ore of shipping-grade. A cave which occurred while the property was idle exposed many carloads of ore valued at \$10 per ton. The Auraria company is a corporation of Denver, California, and Kentucky men.

The Granite Gold Mining Co. is constructing an aerial-tramway from the Dillon to the railroad yards in Victor. A heavy production—100 tons daily—was made during April, the ore being loaded out by team. It had an average value of \$30. The Dead Pine, Upper Granite, and Monument claims of the Granite company were operated by lessees steadily during April.

The mill of the Vindicator G. M. Co., at the Golden Cycle mine, was turned over to the Minerals Separation Co. for alterations and it is understood it will be available to the company by the end of May.

Operations on the property of the Yellow Bird Gold Mining Co. were resumed on May 1, and the extensive development of this old producer is planned under superintendent Yoeckell.

Lessees of the Mountain Beauty Gold Mining Co., operating through the Specimen shaft, are mining and shipping \$30 ore.

MANHATTAN, NEVADA

DEVELOPMENT OF THE MORNING GLORY MINE.—SOME NOTES OF THE GEOLOGY OF THE DISTRICT.

At the new Morning Glory shaft a depth of 40 ft. has been reached and it is expected by the management that ore soon will be found. A second shaft, sunk years ago, is down 70 ft. on what is thought by some to be the same vein as that being developed in the White Caps mine.

The ore from this shaft has all contained gold, running from a dollar or two up to \$17 per ton. Arrangements are being made to sink this shaft deeper, as it is thought, from the appearance of the formation and knowledge of the geology of the district, that high-grade ore will be found below, perhaps within 50 ft. of the present bottom of the old shaft. There is about 1000 ft. of this ore-bearing limestone in the Morning Glory property, and the same length along a second similar stratum of limestone lying north of the first, the duplication being due to the folding and faulting characteristic of the district. In addition to these two possibilities of development, there is a third lime formation running south-east from the Manhattan Consolidated east end-line. This limestone is 300 ft. long in the Morning Glory ground. There is also another outcrop 700 ft. long in this claim where assays show the presence of low-grade ore, in which some stibnite may be seen in places.

The Consolidated company has stoped to the depth of 200 ft. up to the west end-line of the Morning Glory mine, though no development has been done on the latter at this point, notwithstanding the formation continues into Morning Glory ground. It is considered as one of the favorable places where payable ore may be found.

The main mineral-belt of Manhattan district covers both slopes of an anticlinal uplift, extending in an east-west direction across the Toquima range. A normal fault, with north dip, follows the direction of the axis of the anticline. This main fault is accompanied by diverging branches and smaller parallel displacements. These faults evidently ante-date the period of mineralization. There is a much larger number of cross-faults and fissures that extend in a north-south direction, the whole forming a complex system of block-faulting. The blocks between the several cross-faults have been tilted, either north or south, and there is usually observable considerable horizontal displacement, although the vertical movement is usually small. The cross-fractures generally have a steep west dip, and in the west part of the district these fractures are associated with ore deposition, with zones of fracture and min-

THE CAVE IN THE ALASKA TREADWELL MINES THAT LET IN THE SEA

eralization 4 to 10 ft. wide. In the east part of the district the mineralization in the vicinity of these cross-fractures is much less pronounced, but the places where the system of smaller faults crossed the large east-west system have been demonstrated to be the points where orebodies are the most likely to occur. Some of this ore is high-grade.

JUNEAU, ALASKA

DETAILS OF THE CAVING AND FLOODING OF THE GREAT ALASKA TREADWELL MINES.

The Juneau *Alaska Daily Empire*, of April 23, thus describes the flooding of the Alaska Treadwell mines on the night of April 21:

The Treadwell, Mexican, and 700 mines, on Douglas island, owned by the consolidated Treadwell companies, from whose workings 17,000,000 tons of ore has been mined during operations of more than 30 years, are today filled with water from the lowest levels to the tide-level. Fifteen million dollars is the estimated damage done, when, shortly after 11:30 o'clock last Saturday night, a cave-in on the filled-in beach between the 700 mill and the Bunkhouse No. 4 occurred and thousands of tons of water poured through the opening, caused by the break of a stope, into the three big mining properties. Within one hour every man, except possibly one, reached the surface and

every level of the various mines was filled with water. Two of the company's houses, the Treadwell natatorium and the Treadwell fire hall, caught in the maelstrom caused by the cave-in and the rushing high-tide water, swung around and around, then disappeared into the hole, lost to view, even at low tide.

Shortly afterward the huge oil tank situated on the beach near the 700 mill collapsed and the steel frames were twisted like paper, and fluid, which half filled the tank, poured out and, being sucked down by the intruding water, found its way through the various levels of the mine and emerged in the old Glory Hole, a thousand feet distant.

Today huge cracks in the earth extend from the 700 mill, up the hill to the old Glory Hole and down to the mess-house end on the baseball grounds. All those living in the houses on the hill moved out early yesterday afternoon when the cracks began to appear. Bunkhouse No. 4 is today out of plumb by six feet, ready to slide into the abyss. The clubhouse is also equally as much out of plumb, and all are conjecturing when the next slide will occur and how far its ravages will be felt.

The Ready Bullion mine is believed to be safe. Trickling of water started soon after the three larger mines were filled, but immediately men were placed at work and an immense concrete bulkhead was started as an additional brace to the one already in place, and this bulkhead today is holding.

Today there are approximately 1000 miners temporarily out of positions, although scores of these men are being used on the surface, protecting mills, shops, etc., and adjusting conditions either to expedite speedy dismantling of valuable machinery or in preparing for work which will insure the opening of the mines now filled with water. Operations today, outside of those above mentioned, include the Ready Bullion mine and mill, foundry, cyanide-plant, Treadwell store and warehouse, and all power plants, fully 500 men being employed in these operations.

Guards are stationed around all danger points and no one is allowed to come within 1000 to 1500 ft. of the places

which are now in a precarious condition.

When the first rush of water was noticed Saturday night, warnings were immediately sent out and signals displayed through the various levels where miners were at work. The excellence of this 'safety first' system easily describes why, out of 350 men below the surface at the time, only one has been reported missing.

Today groups of miners, many with their families, are waiting anxiously for the next step, either to be made by the unseen power of water and earth, or a cessation of anxiety and the word from the company officials as to the next move to be made.

OATMAN, ARIZONA

THE UNITED EASTERN DEAL CONSUMMATED.—THE OLD MOSS MINE BEING UNWATERED.—HIGH-GRADE IN GOLD ORE.

The sale of the Big Jim mine to the United Eastern Mining Co. was ratified on April 24 at a stockholders' meeting held at Phoenix, Arizona, where over two-thirds of the capital stock was represented. Secretary Warmbath states that the office-work incident to distribution of United Eastern stock to stockholders of the Big Jim Gold Mining Co. will be finished this week and that the stock will be distributed the last of the week. Superintendent Keating, who remained in charge of the mine

during April at the request of superintendent Burgess of the United Eastern, was relieved of his duties May 1, and will commence work at the Bluebird for the Big Jim Consolidated, which succeeds Big Jim Gold. At the time United Eastern stock is distributed stockholders of Big Jim Gold also will receive share for share of Big Jim Consolidated.—W. H. Holcomb, of San Diego, representing a syndicate of St. Louis and West Virginia capitalists, is unwatering the old Moss mine, near the Colorado river. The shaft is 330 ft. deep and there are 1200 ft. of lateral workings on the 300-ft. level. The water stands to within 100 ft. of the collar of the shaft. A gasoline-hoist and bailer have been installed and actual bailing is progressing. It is anticipated that three weeks will be required to unwater the mine. The mineralized lode is 250 ft. wide and is said to average \$9 per ton. On the dump is ore valued at \$30,000. The mine is mortgaged to the First National Bank, of San Diego, for \$65,000, including interest charges. The syndicate, Mr. Holcomb says, is prepared to pay this mortgage if the mine samples to their satisfaction. The Moss mine is five miles north of Oatman and has been worked at intervals for forty or fifty years. Rich streaks of ore were mined and the ore milled on the Colorado river, seven miles distant.—The Gold Ore winze is down 105 ft. below the 530-ft. level and in the richest ore yet developed. The vein is seven feet wide and half of it carries \$1000 per ton, according to advices from the mine. The ore is identical in appearance with the Gold Road ore. In the Gold Road mine high-grade shoots, like this, frequently were encountered. J. F. McConnell, who with Joe Perrizo owned the United Eastern ground, has purchased large holdings in the company. A new shaft and a mill are planned for the near future. A. C. Werden, of Gold Road, is manager.

PORCUPINE, ONTARIO

PROBABLE CURTAILMENT IN OPERATIONS.—A LARGE FOREIGN ELEMENT PRESENT AMONG THE MINE WORKERS.—A STRIKE FEARED.

Despite the fact that Hollinger Consolidated, during 1916, made a net profit of approximately \$3,000,000, and ore reserves are estimated at \$33,000,000, there are rumors that production at this mine may be curtailed to permit increased development work. Efficient labor is difficult to secure, and as a consequence, costs show an upward trend.

During last week, Dominion Government officials were in the district and arranged for the taking of a census of the alien-labor employed here. It was discovered that about 70% of the mine workers were aliens, about 40% of them being alien enemies. The taking of the census and the compelling of all alien enemies to report at designated offices at regular intervals has served to allay much of the uneasiness that for some time has been apparent among these workers, and which it was generally feared, would lead to labor troubles, and perhaps to a strike. The union will hold its annual convention at Cobalt, on May 7, and until that time, and perhaps even later, it will not be known whether a demand for increased pay is to be made. The general outlook, however, is brighter than a week or so ago.

The mill at the Dome Mines is now running at only 60% capacity, and here, too, curtailment of production is likely. That development work at all the mines will be urged vigorously appears evident, that is, unless the company is forced to close down entirely, due to the unreasonable demands that the mine workers may make.

The McIntyre-Porcupine continues to attract much attention. The big orebody at the 1000-ft. level continues with the same width and value, having now been opened up nearly 1000 ft. long. The 600-ton mill at this property is treating 500 tons daily. The mill-heads are being maintained at around \$11.80,

and gold bullion is being produced at the rate of approximately \$150,000 monthly.

BRITISH COLUMBIA

SOME OF THE MORE IMPORTANT MINES OF THE WINDERMERE MINING DIVISION.—NEW DEVELOPMENT AND ORE SHIPMENTS.

The Windermere Mining Division is situated in the south-east part of British Columbia. The Golden Mining Division lies on the north, Alberta on the east, Fort Steele Mining Division on the south, and Ainsworth Mining Division on the west. It has an area of approximately 5500 square miles. Upper Columbia lake, the source of the Columbia river, lies near the southern boundary of the division. The Kootenay Central railway furnishes transportation for the Division, and runs from Golden on the main line of the Canadian Pacific south to the Crows Nest Pass branch.

Prospecting for mineral in the division has been almost wholly confined to the Selkirk range, west of the Columbia river, and the lakes between Findlay creek and its tributaries, and Salmon river and its tributaries. The area is about 48 miles long, north and south, and 25 miles wide, east and west. The prospecting thus far done has not been very thorough, but the veins discovered are remarkable for their strength and continuity. Much of the area is still a virgin field to the prospector. Some of the mines that have been developed in the Windermere Division are the following:

The Paradise mine is situated on Spring creek. It consists of a group of five claims, that were located in 1899. It had shipped up to 1904 about 2000 tons of ore that averaged 51.4 oz. silver and 59.3% lead. Between 1903 and 1916 the property was idle, but during 1916 R. Randolph Bruce, the manager, decided to re-open the mine, and since then 20 men have been employed and 20 teams have been required to haul the ore to the railroad. From October 1, 1916, to January 31, 1917, 1050 tons was shipped. The greater part of this ore contained 40 oz. of silver and 40% lead per ton. In the meanwhile a dump of 2000 tons of low-grade ore had accumulated, from which 200 tons was sorted out last fall and shipped. This ore ran 25 oz. silver and 25% lead. Much re-timbering and cleaning-up was necessary in the old workings, and this has hampered work somewhat. Shipments at present approximate 150 tons per week. Within the past three months several new stopes have been started and some rich ore found. The vein has been followed down to the fourth level and the shoot is known to be 1000 ft. long. The ore carries both carbonate and sulphide of lead, with iron oxide, in a gangue of silicious lime. The enclosing formation comprises a series of shale, slate, and sandstone, intercalated with occasional beds of limestone. The ore is so desirable in lead-smelting that the Trail smelter makes a special rate on transportation and smelting-charge.

The Silver Belt group adjoins the Paradise property, and is owned by C. M. Keep of Washougal, Washington. The mine has been idle for many years. It is stated that in 1901 a shipment of 15 tons was made that averaged 218 oz. silver per ton. Last year a few cars of ore was shipped and it is now reported that work is to be resumed.

The Hot Punch mine, controlled by J. E. Stoddard, of Windermere, B. C., is on the north fork of Toby creek. Several hundred feet of development work has been done, and 50 tons of ore is on the dump ready for shipment. This ore averages 0.1 oz. gold, 49.3 oz. silver, and 38% lead per ton. The most westerly opening on the property is a shaft 90 ft. deep in which the vein is 1 to 3 ft. wide. The ore in this shaft averages 0.05 oz. gold, 39.2 oz. silver, and 66.6% lead. Another vein carrying high-grade ore was discovered on the property in 1916.

The Sitting Bull group at the head of Boulder creek comprises the Sitting Bull, Alice, Colorado, and Mary G. mines. In 1898 about \$6000 was expended in development, but as the

holders of an option on the property could not get an extension of time work was discontinued. An option was taken on it in 1916 by the Sitting Bull Mining Co. and work was started late in that year. The early work consisted of a shaft 50 ft. deep, which produced some high-grade ore, several open-pits at various points along the vein, and a cross-cut adit. This latter is being driven to the vein. On the Mary G. claim the vein is exposed for 300 ft. and an adit has been run on the vein, which shows 20 in. of galena. In the Alice there is an 18-in. vein of high-grade galena. It is the intention of the company to develop the property and then to build a wagon-road from Horse Thief creek to the head of Boulder creek, where a gravity-tramway will connect with the mine.

The Isaac mine, owned by H. E. Forster, is on a small branch of No. 3 creek. The property comprises a group of four claims though all of the development is on the Isaac claim. The ore is taken to the head of the rawhide trail by a 1500-ft. aerial tramway. It is then packed in summer, or rawhided in winter, 3 miles to the wagon-road, and hauled in wagons 12 miles to Brisco, on the railroad. Four cars of ore was recently shipped which ran from 35 to 40 oz. silver and 35 to 65% lead per ton. Development will be continued during 1917 and large shipments will begin in the fall and continue throughout the winter. It is less expensive to rawhide ore along the trail on the snow than to pack it on animals.

The Lead Queen—a group of five claims—is situated on a tributary to No. 3 creek, and is owned by Thos. Brown and J. M. McLeod. The vein is from 2 to 4 ft. wide and can be traced through the five claims. Where developed, on the adit-level, it carries from 6 to 24 in. of solid galena and about 3 ft. of ore of lower grade. Ore is being shipped.

TORONTO, CANADA

THE LABOR TROUBLES CONTINUE IN SEVERAL DISTRICTS OF ONTARIO.—INCREASING OUTPUT IN IMPORTANT MINES.

The mining industries of northern Ontario are threatened with a serious disturbance over the labor question. There is a marked shortage of labor and a strong agitation for an all-round increase in wages of 50c. per day. By way of compromise, several of the Cobalt companies are now paying bonuses based on the selling-price of silver, which practically equal the demands of the men, but others have refused any concession, and the mine-owners decline to enter into any negotiations on the ground that this would involve a recognition of the Western Federation of Miners, with which the Union is affiliated. In the Porcupine and other gold districts the mine-owners are apparently determined to refuse any increase, stating that owing to the increased cost of material they are not in a position to pay higher wages and that skilled workers are already receiving as much as is asked for by the Union. According to a statement by P. A. Robbins, manager for the Hollinger Consolidated, the trouble is mainly due to the large foreign element, including many Austrians and Bulgarians who have been released from internment camps to work in the mines. These men, who have made good wages, have lately become slack and show a spirit of indifference and insubordination, and it is feared that serious trouble may break out at any time. The English-speaking workers are represented as being well satisfied with present conditions. Government officials last week took a census of the aliens employed in the mining districts, which is stated to have had a good effect in quieting down the unruly element. No decisive action on the part of the men is expected before May 7, when the mine workers will hold their annual convention at Cobalt.

The Hollinger Consolidated during the four-weekly period ended March 25, made a gross profit of \$210,749, being \$87,749 in excess of the dividend requirements, and reducing the deficit to \$122,873. The ore treated averaged \$8.67 to the ton and the working cost was \$3.97. During the four-weeks period the sum of \$82,963 was spent on new equipment.

Vein No. 58, on which spectacular ore was recently discovered, is holding out well. For 100 ft. the orebody averages \$50 per ton, and is 14 ft. wide, with no sign of diminishing. The face of the vein is 400 ft. from the McIntyre boundary, which company is diamond-drilling to pick up the vein. The drill will explore a part of the McIntyre property that has not so far been prospected at depth.—The shaft on the Jupiter property is being sunk to the 1000-ft. level.—The cross-cut at the 600-ft. level of the Vipond-North Thompson has cut the vein at 50 ft. from the main shaft, where it is well mineralized. The mill is treating about 100 tons of ore daily.—The main vein of the West Dome Consolidated, which is being driven on at the 300-ft. level, has widened to 10 ft., assays showing increased gold content. The vein has been proved up by diamond-drilling for 2200 ft. and to a depth of from 600 to 700 ft.—Material for the construction of an addition to the Schumacher mill is on the ground, but the work has been postponed owing to labor shortage. During March the production was valued at \$20,000, and the expenses were \$16,500; operating costs running \$4.30 per ton. As the margin of profit is only about \$1 per ton, operation may be curtailed in the event of labor troubles.—The Rypan, which has a property of 188 acres adjoining the Bewick-Moreing claims, is showing a number of promising veins and is preparing for development.—At the Hollinger Reserve the vein is the full width of the shaft at 300 ft. and carries free gold. The shaft is being put down to the 400-ft. level.—Ralph Regnall has been appointed manager of the Dome Lake, in place of Harry Darling, who recently resigned.

The Temiskaming & Northern Ontario Railway Commission has appropriated \$125,000 for the construction of a branch line from Swastika to Kirkland Lake, but construction may not proceed for some time.—At the Wright-Hargraves, in Kirkland Lake district, the vein, which is 12 ft. wide on the surface, has widened to 20 ft. on the 100-ft. level with a gold content reported at \$50 to the ton.—A test-pit, sunk about 10 ft. on the Canadian Kirkland has yielded encouraging results, the ore in a 3-ft. vein showing free gold.—The first shipments of precipitate from the Teck-Hughes has been sent for treatment to the Buffalo mine refinery, which will handle the Teck-Hughes precipitate until arrangements can be made for its treatment at Kirkland Lake.

At the Nipissing, during March, ore was mined of the approximate value of \$256,953 and bullion was shipped from Nipissing and from custom-ore of the estimated net value of \$401,038. The report for the year 1916 shows profits of \$2,028,866, as against \$1,403,484 in 1915, and a balance available for dividends of \$1,805,244. Upward of \$193,000 was added to the surplus, which amounts to \$1,980,126. The shipments for the year contained 3,819,768 oz. fine silver, valued at \$1,980,126, and the total production of silver was 4,044,668 oz. of the net value of \$2,955,062. The cost of production was 24.13c. per oz., as compared with 19.06c. in 1915. The ore reserves were estimated to have a value of 9,153,000 oz. silver.—The annual report of the Beaver Consolidated for the year ended February 28, showed earnings of \$499,690 as against \$351,124 for the preceding year. There was a balance on hand of \$236,582, bringing the aggregate balance up to \$639,821.—The Temiskaming is cross-cutting at the 1600-ft. level to reach the high-grade vein recently struck at that depth on the Beaver. The main shaft will be put down to 1800 ft.—The Coniagas is putting in additional tube-mills in order to increase the capacity of its flotation-plant to 500 tons per day. It is estimated that there are about 200,000 tons of slime and tailing to be re-treated containing from 3 to 6 oz. of silver per ton.

As a result of experimental work now being conducted at the Buffalo & Dominion Works by the inventor of the Holt-Dern process, the main objection to flotation in Cobalt seems about to be removed. Not only are experiments meeting with success in the treatment of flotation concentrate, but it would also appear that table-concentrate may be treated satisfactorily.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

The current production of the Kennecott Copper Co. of about 7,000,000 lb. per month from the Alaskan properties constitutes a normal yield for this time of year. Through the summer months operations will speed up somewhat and the output may again equal the high figures of a year ago when for several months it ran above 10,000,000 lb. of copper.

Officials estimate that the current year will show fully as great production from Alaska as did 1916, or approximately 110,000,000 lb. Costs will be somewhat higher on account of the payment of higher wage bonuses. From the Beatson mine production now runs slightly better than 1,000,000 lb. per month, and by July the capacity should be sufficiently increased to permit of a yield closer to 2,000,000 lb. per month.

The work of doubling the capacity at the leaching-plant at the Bonanza mine should be finished during the next few months. This now has a capacity of close to 500 tons daily and will be increased to handle 1000 tons of tailing daily. The extraction from the Bonanza ore has been better than 90%; recovery from the tailing exceeds 70%.

Ore running 65% copper still figures prominently in shipments from the Bonanza mine. This, along with concentrate and precipitate, goes to the Tacoma smelter of the American Smelting & Refining Company.

ARIZONA

GILA COUNTY

The Arizona Commercial Co. with mines near Globe is increasing its output. The production in April was about the same as that in March, but in May it is expected to be well over 500,000 lb. It is thought 6000 tons will be treated and that soon as much as 700,000 lb. will be produced monthly. On the 8th level it is reported that the orebody is 45 ft. wide, of which 40 ft. averages 4% copper, and 5 ft. next to the hanging wall carries 9%. The 10th level is developing well, 80 tons of 11% ore having been mined there daily of late.

MOHAVE COUNTY

It is reported that rich ore has been found in the Diamond Joe mine in Cedar district, near the McCracken mine. An adit is being driven on the vein, which is getting wider as the work progresses.

The development of a molybdenite prospect in the Hualpai mountains, 15 miles east of Kingman, is in progress. The property is known as the Jackman mine. The ore is described as similar to that in the Leviathan, in the same district, but carries less copper.

Development is progressing with good results at the McCracken, where a large amount of silver-lead ore is being developed.

A new mining district has been formed 25 miles west of chloride, to be known as the Weaver district. The necessary steps for the formal creation of this new district were taken by 40 property owners there. It is composed of the two old districts, the Weaver and Minnesota. There are said to be many good prospects in the region.

CALIFORNIA

The State oil and gas supervisor, R. P. McLaughlin, states that the amount of crude oil stored in California is only about two-thirds of the amount on hand two years ago. This condi-

tion exists notwithstanding the fact that there are now more wells producing than at any previous time, and new wells are being drilled at a rate seldom exceeded in the past. Such a condition is worthy of serious consideration at the present time, in view of the dependence of many of our industries upon fuel-oil.

Development during the week ended April 28, as shown by reports made to the State Mining Bureau, shows no cessation in efforts to increase the production of oil. There are twenty-one new wells commenced, making a total of 372 since the first of the year, against only 216 during the same period last year. About the same rate of increase is noted in the work of deepening or re-drilling wells, the weekly report showing twenty-seven such jobs, making a total of 276 since the first of the year, as compared with 166 at the same date last year. A scarcity of casing is causing many old wells to be abandoned and second-hand casing is going into the construction of many new wells.

AMADOR COUNTY

James Giambruno, secretary of the Mother Lode Miners' Union, announces the secession of that organization from the Western Federation of Miners, on the ground of dissatisfaction with the parent union during the strike of last fall. Giambruno says the local branch of 800 members has paid in \$5000 in assessments to the parent organization and that during the strike, the local workers received nothing from the Western Federation of Miners. A district union will be formed, to include the miners of Amador, Calaveras, and Tuolumne counties.

CALAVERAS COUNTY

(Special Correspondence.)—The mill at the Mokelumne group of mines, controlling interest of which is held by Max Müller, of Los Angeles, is running one shift on ore from the West-adit stopes on the Easzy Bird claim. The mill is a Joshua Hendy 100-ton ball-mill, having a ball-charge of 6000 lb. It is the best-equipped mill in this district. Mr. Gleason, formerly at the Plymouth Consolidated mine, in Amador county, is mill-foreman. Sinking is in progress, the shaft being down 100 ft., and a cross-cut is being run. The ore-shoots are all in the east and west veins. Good ore is found at the bottom of the shaft, but just how much has not been given out. S. Titus, formerly of Silver City, New Mexico, is foreman, and Mr. Howett, also of New Mexico, is superintendent.

The company operating the Safe-Deposit gravel mine, situated about a mile from Mokelumne Hill, has constructed debris-dams in first-class shape, having spent \$20,000 in this work. Mr. Burgess, the superintendent, says he is now ready to begin operations. It was a paying property in the past.

The Boston mine, situated a mile below the Mokelumne group, is about to begin operations once more, having been closed down for 13 years. Probably 100 men will be working shortly. It is now owned by Sam Davidson, of Mokelumne Hill.

At the Maypole quartz mine, half a mile from town, the adit is in 300 ft. and driving to catch an ore-shoot cut at the bottom of an old shaft sunk in the early days. Some very rich ore was milled from the shaft that is now being re-timbered.

At the Lucas mine, about $\frac{1}{2}$ mile from the Mokelumne group, ore averaging \$100 per ton has been found. It is free-milling. There is a good mill-site and a good head of water available. The vein averages 30 in. wide. Robert Irvine of Mokelumne Hill is the owner. The mine is being prospected

thoroughly. Antimony and tungsten have also been discovered recently in this vicinity and prospects for this district are now better than in many years.

Mokelumne Hill, April 28.

Dorroh and Cuneo have arranged with James V. Coleman for the right to work the tailing from the Angels mine, which has settled in China gulch since the mill was started, says the *Record*. Samples prove that the tailing carries sufficient value to pay, and a plant has been erected for the purpose of treating it.

This plant is in operation and consists of an Australian grinding-pan, or Freeman pan, as it is sometimes known, the first one to be put in operation in this country. It is driven by a 20-hp. gas-engine and is equipped with the usual amalgamating-plates and burlap-slucies for saving the fine sulphides.

The Australian grinding-pan is something new in grinding-devices on the Mother Lode and was manufactured at the Angels Iron Works, at Altaville, from plans and specifications by the inventor. W. J. Loring saw these machines in use in Australia and through him the Angels Iron Works has secured the American rights to the invention.

The pan consists of a heavy cast-iron bowl with vertical sides. It is about 5 ft. in diameter, 3 ft. deep, and lined on sides and bottom with cast-iron dies and liners. The muller is provided with wearing-shoes that are renewable. This muller makes 30 r.p.m. when used on thin pulp and may be run faster if conditions permit using less water. The fineness of the grinding is regulated by the discharge-pipe which may be moved in or out from the centre of the pan and the fineness of the product varied by so doing. A string of sluices has been placed in China gulch and the tailing is shoveled into them and is carried to a screen where the grass-roots, vegetation, and the larger stones are removed; the fine tailing then flows to the grinding-pan and when it has been ground sufficiently it flows over two amalgamating-plates, each 24 in. wide and 8 ft. long, and then over four burlap tables, each 18 in. wide and 8 ft. long, and is then discharged into the creek. The grinding-pan takes about eight horse-power to run it and it is said to have a capacity of 70 tons per day. Five men are employed at present.

NEVADA COUNTY

When the first level of the Allison Ranch mine had been unwatered it was found that an 18-in. vein was exposed in the face of the drift. This level will be cleaned out and re-timbered and exploration commenced. The water is going down in the shaft at the rate of 20 ft. daily, though the time that will be required to unwater the several levels will depend on the extent of the old workings, and also on the amount of water coming in, which will increase somewhat with greater depth, and until the zone of saturation has been drained.

Seventeen miners of Grass Valley have volunteered for military service and have left their homes for a training-camp. Nearly all of these men are said to be from the crew of the Empire mines.

SAN BENITO COUNTY

The three furnaces of the New Idria Quicksilver Mining Co., which had been closed down for repairs, are again running and the output of metal is being increased. During April the output was a total of about 900 flasks, which is expected to be increased to 1000 flasks during May. New Idria is now earning at the rate of \$6.50 per annum, and paying dividends of \$1 per share quarterly.

SAN BERNARDINO COUNTY

At Goldstone two shifts are at work in the Goldstone company's mine. The property is well equipped with machinery, such as is required in the desert region. The shaft of the Double C. is being deepened. The Goldstone Mining Co. is

about to begin work on the property it recently bought from the Redfield brothers.

SHASTA COUNTY

Preparations are being made to sink a new shaft at the Stowell mine for the purpose of mining a new orebody that was discovered by diamond-drilling.

The new shaft will be sunk 300 ft. below the present workings to get well under the new orebody. During the sinking operations the shipping of ore from the mine to the Kennett smelter will be discontinued.

TRINITY COUNTY

(Special Correspondence.)—The Gold Standard Consolidated Mines Co. of Oakland, California, has taken a bond on the Blair property, comprising five claims and situated nine miles west of Coffee, in the Salmon range, and has started development. The principal vein has an east-west strike, dips north 60°, and can be traced on the surface for 2000 ft. It shows a width of two feet at the bottom of a 55-ft. incline. The ore runs \$24 per ton. A 232-ft. cross-cut adit cuts the vein 5 ft. wide, 165 ft. below the surface. The ore averages \$36 per ton. In a 35-ft. drift, running east, samples go \$97 per ton. The ore is free-milling. The foot-wall is porphyry and the hanging wall is schist. It is intended to build a 20-ton plant. There is an abundance of timber and water-power. J. R. Blair, of Weaverville, is the owner. The company holding the options is composed of Oakland men. Lincoln Brodt is president, Frank Driesbach, vice-president, and C. A. Munroe, secretary-treasurer. The deal was brought about by L. Grames of Coffee. William Briggs is in charge of the work.

Atkins, Kroll & Co., of San Francisco, has men at work testing the ground of the Carter & Williams hydraulic property on the North Fork of Coffee creek, on which they have a bond. Most of the work will be done with a self-shooter. Frank Rose is in charge.—Stuart & Phillips have a force working the Schlomberg hydraulic mine on the North Fork of Coffee creek. The mine is equipped with both a self-shooter and a pipe-line. Henry Carter is in charge.

Coffee, May 2.

TUOLUMNE COUNTY

At the Monarch gravel claim a milling-plant is being installed and will be in operation in about two weeks, says the *Democrat*. This property is situated on the South Fork of the Stanislaus river on the Hiatt place and shows a good prospect in the gravel of the ancient channel for which an adit is being run. Theodore DeMauris is the superintendent. The value of the gravel thus far uncovered is such that it can be washed at a good profit.

A station is being cut on the 800-ft. level of the Confidence mine, and everything is in readiness for starting the development work planned. It is proposed to sink the shaft another 800 ft. and explore the ground below the old levels. Fifteen men are working, but this force will be increased as soon as the conditions will permit.

The three-compartment shaft on the Yosemite mine, adjacent to the Rawhide, has reached a depth of 120 feet.

The F. J. Munn ranch property at Moccasin Creek has been leased by W. S. Fagan, J. A. McAllister, and L. L. Coffey, who will explore it for copper.

COLORADO

The road leading up to the Josephine mine, in West Argentine, has been cleared of snow, says the *Georgetown Courier*, and shipments of lead ore are about to begin for the season. Miners have been breaking ore throughout the winter and a large amount is stored in the mine.

The Wasach-Colorado Co. is working at full capacity, shipping ore to Idaho Springs. The Stevens mill is also running to its fullest capacity, treating ore for the company and from Stevens lease as well. New ground is being opened as fast as timber can be obtained to secure the workings.

The Hamill adit of the Philadelphia Mines & Tunnel Co. is believed to be nearing the Mendota vein, which it is thought passes through the property. The Mendota is employing a large force and is producing several hundred tons per month. There is much difficulty in securing experienced miners in the district.

LAKE COUNTY

Sinking at the Jamie Lee shaft of the Leadville Unit on Fryer hill, is progressing under favorable conditions. At a depth of 115 ft. below the old shaft bottom, a new pump-station has been cut in the white porphyry and machinery installed. The large water-course which has been causing so much trouble in the shaft has been intercepted by a drift from the new station and the water is being drained to the pumps. This project has made such a great change in the flow now entering the shaft that one small sinking-pump is able to keep the sump well drained.

The Jamie shaft is nearing the 670-ft. mark, 140 ft. having been gained since sinking was started.

The drill-hole that was being put down alongside the shaft has reached the Cambrian quartzite, having pierced the white lime. No important results are reported by H. S. Lee, the manager. A second hole is being put down in another place.

SAN JUAN COUNTY

The old Guston mine, near Silverton, again will be worked. Plans are well under way whereby lessees will operate this property during the coming summer. This mine is in the Red Mountain district and was an early-day producer of an immense tonnage of high-grade ore. It is said that several millions of dollars worth of ore was shipped from it during the early '90s.

After the slump of silver in 1893 the property was closed and has only been worked intermittently since that time.

SUMMIT COUNTY

The Gold Queen property at Kokomo, which was the scene of a rich strike several months ago, continues to produce high-grade silver ore according to late reports, says the *Carbonate Chronicle*. Last week two cars of high-grade ore were shipped from the property, the ore being reported as the best that has yet been extracted. It is stated that a large tonnage of the ore is blocked out and a larger output will be shipped during the summer.

TELLER COUNTY

Fred Sutherland, of Victor, is making good progress in the Llewellyn shaft and has already enlarged the first 50 ft. of the 230-ft. shaft, to two compartments. With the shaft enlarged and re-timbered, sinking will commence. The shaft is to be sunk approximately 500 ft. to correspond with the 600-ft. level at the Golden Cycle sixth level, from which the Excelsior Mining, Milling & Electric Co., holding a long-time lease on the Longfellow group, is now mining its ore.

Lessees working over the dump at the main shaft of the Requa Savage Gold Mining Co., on the north-east slope of Beacon hill, sent out a car of ore recently to the smelter.

An electric-hoist for installation at the shaft near the big open-pit of the Rex Gold Mining & Milling Co. on the south slope of Ironclad hill, has been hauled over from the Rubie mine on Bull hill. Thomas Kavanagh and associates are shortly to resume treatment at the Ironclad mill of the Rex company, and soon will be treating close to 100 tons daily of low-grade ore.

IDAHO

LEMHI COUNTY

An important strike of lead-silver-gold ore is reported to have been made in the old Yellow Jacket mine, 50 miles west of Salmon. This mine was discovered and worked extensively 30 years ago. At that time the mine was developed and equipped in what was considered an elaborate manner, but

the management lacked experience. The orebodies were faulted and the character of the ore changed with increasing depth. Metallurgical knowledge was deficient and the whole enterprise lapsed into idleness. The 60-stamp mill, and other buildings, tramways, the water-systems, and all other equipment went to ruin. In addition to this a large amount of money was spent in a fruitless search for the faulted vein. From the original orebody a large amount of gold was produced, but the silver, lead, and copper were lost. The new strike of ore is considered as the most important development made in the Salmon district in 20 years.

SHOSHONE COUNTY

Search for an extension of the orebody that has yielded several millions of dollars to the Caledonia Mining Co. is the purpose of the Wardner Leasing Co., for which articles of incorporation have been filed at Wallace. The work of sinking a shaft to a depth of 400 ft. has been started. Mining men are interested in the operation because of the problem involved. This concerns the situation of an ore-shoot cut off by the Kellogg fault. The subject involved a geologic study at which W. A. Beaudry spent a year and a half. His deductions have satisfied others. The scene of operations is on the same side of the fault as the Bunker Hill & Sullivan mine.

Aside from the geological phase, Mr. Beaudry was confronted with a leasing problem. He was able to obtain concessions from the owners of more than 200 lots, but lacked the privilege of mining under the streets and alleys of the town of Wardner, which was not legally authorized to grant this privilege, so it became necessary to obtain the passage of special legislation at Boise permitting it do so. The company has thus acquired the right to mine in an area equivalent to about four claims. The shaft is going down and will have attained the horizon of prospective exploration early in the summer, according to present expectations.

MISSOURI

JASPER COUNTY

For a consideration reported to be between \$350,000 and \$400,000, the St. Louis-Joplin Lead & Zinc Co. has sold its 400-acre tract of mining land in the Chitwood district to the Inter-State Royalty Company of Kansas City.

The Inter-State Royalty Co. is a \$400,000 corporation made up principally of Kansas City investors. E. R. McClelland of that city is its president. He is also president of the St. Regis Lead & Zinc Co., which has the mine in operation on the tract purchased and also has an excellent sheet-ground mine at Duenweg.

Some promising strikes have been made lately in the southern edge of the Lawton-Waco field by W. W. Booth and R. D. McIntosh, of Joplin. Three holes have been put down and good ore encountered in each.

The drilling has been done on the W. G. Burgess farm, north of Carl Junction. In the first hole a run of only five feet of ore was found. The drillers moved off a short distance and tried again, and in this hole a rich run of 15 ft. of ore was struck. Another move was made and the ore face indicated by the cuttings was a full 20 ft. thick. Another hole has been started and if the good luck continues another mill-site will have been proved.

The ore-runs are found at comparatively shallow depth, and the formation is reported to be exceedingly promising, indicating that the same nature of deposits may be expected as are found a few miles to the north, where so many rich prospects recently have been developed.

MONTANA

MINERAL COUNTY

Four carloads of ore, two of them on Saturday last, have been shipped from the Intermountain mine, Iron mountain,

since the restoration of transportation facilities three weeks ago.

Five to six carloads of concentrated ore is awaiting shipment, and five to six carloads of crude ore is broken in the stopes. The concentrated ore has been settled for on a basis of about \$2000 net to the carload. The crude ore is about 12% copper. Unwatering the 700-ft. level will begin soon after the receipt of a pump shipped from Chicago three weeks ago. A stope will be opened to the 700-ft. level.

SILVER BOW COUNTY

The Anaconda Copper Co. has donated to the State of Montana the free use of 100 acres of irrigated land, and several thousand of non-irrigated for cultivation, to feed inmates of State institutions. The Butte Water Co., controlled by the Anaconda company, has offered free water to the people of Butte for gardening purposes.

NEVADA

CLARK COUNTY

Concerning the operations of the Rand Mining Co. in El Dorado canyon, the *Miner* says: The mine and 10-stamp mill have been operating two shifts for some months past and at the same time the mill has been undergoing many improvements and additions to increase the output, as the large tonnage of ore reserve is increasing daily. The mill is equipped with amalgam plates and Wilfley tables. For the first two weeks of April the mill-heads carried a straight average of \$27 per ton in gold with a small amount of silver. The highest grade ore put through the mill ran \$50. The average of concentrate for the first 15 days of April was \$400 per ton; the highest concentrate, \$730 per ton. Shipments of ore were made to the reduction-works at Salt Lake City, which gave an average of \$500 per ton, with the highest value at \$2500 per ton.

In addition to the above the Lombard-Carnation and the Techatticup are running on good ore. The Techatticup is milling ore that runs from \$20 to \$25 per ton, and it is expected that the Lombard-Carnation will average nearly \$40 for the next month or two, as an amount sufficient for a run of several months has already been mined and sampled.

The Colorado-Nevada company for seven months of 1916 showed an average of the mill-heads of \$14.65 per ton. The orebody of the Colorado-Nevada varies from 10 to 32 ft. wide.

NYE COUNTY

Unwatering of the Union Amalgamated mine has been completed and a pump-station cut on the 600-ft. level. As soon as the pump is in position east and west cross-cuts will be extended in the orebody. The mill is running steadily on good ore from the upper levels. The property is controlled by Mushett & Wittenburg. Samuel Durkee is superintendent.

Sinking of the 200-ft. shaft of the Manhattan Consolidated to an approximate depth of 400 ft. has started with three shifts. At the 200-ft. point the vein is over 40 ft. wide and the shaft is expected to enter ore between the third and fourth levels. Mark Page is superintendent.—The Manhattan Uncle Sam Co. has been formed by William Darst and associates, of Venice, California, to work 75 acres adjoining the Portland and Annie Laurie properties.—Arrangements have been made for resumption of work on the Lucky group by Omar Maris.

The Crescent district, about two miles from Nipton, on the Los Angeles-Salt Lake railroad, is attracting considerable interest. James E. Keelyn, of Pasadena, California, has placed a hoist and compressor at the Keelyn silver-lead mine preparatory to sinking the 90-ft. shaft to considerable depth. At the 90-ft. point a 10-ft. vein of high-grade ore is exposed. The same company is operating a gold property in the district. Eastern people have acquired the old Toberg property and work has started under direction of William Hennessy. The Oro Fino, Sheerer, and other properties have been taken under

option by representatives of Eastern capital. The district lies on the line of California and Nevada. Crescent is the nearest camp.

In the old Sweetwater district the Nevada Progressive Mining Co., composed of Chicago people, has arranged for a plant, with a capacity of 50 to 60 tons daily, at the Sweetwater group. Equipment will include a Denver quartz-mill, concentrators, and Koering cyanide-machinery. Shipments of silver-gold ore are being made to the Hazen sampler, assays average \$59 to \$108 per ton. J. S. Dawson, the manager, states that ore-reserves are placed at \$300,000, with about \$100,000 in shipping material on the dumps. The mine is well equipped.

The Atkins, Kroll Co. of San Francisco, has arranged to place its tungsten mines and plant in operation at Sodaville. Considerable work was done last summer and large deposits of ore were exposed, but the slump in the price of tungsten brought about suspension of activities in the fall. It is said 150 men will be employed.

STOREY COUNTY

Whitman Symmes, superintendent in charge of the Combination shaft operations of the Middle Mines Association of the Comstock, says that on April 29 No. 1 pump at the shaft was placed in operation, and its first run showed excellent capacity. At the rate noted thus far, the pump will lower the water about 10 ft. per day. A second pump is being placed in readiness for lowering and use in the shaft as required. The levels long submerged are again to be opened for careful and thorough prospecting in ground that has never been opened, but which is believed to hold great possibilities.

Work is in progress on the 2900-ft. level of the Mexican mine on the Comstock for the first time since 1885, that level having been under water for 32 years. Ore broken in the Mexican below the 2700-ft. level last week averaged \$59 per ton. Five bars of bullion was shipped, principally the result of Mexican operations. The Sierra Nevada continues to develop good ore on the 2450 and 2700-ft. levels. On the 2500 the north drift has been opened for 760 ft. and the face is approaching the east cross-cut where many years ago ore was found but not developed.

OKLAHOMA

OTTAWA COUNTY

On the south 20 acres of its lease, near Century, the First National Mining Co. of Miami reports a drill-strike that is declared to equal any yet made in the field, says the *Joplin Globe*. A 25-ft. face of ore is indicated by the strike, and the cuttings are said to show an average assay for this face of 36.9% zinc.

The First National company already has developed a fine mill-site on the north 20-acre lease it owns, and a shaft at this point is down to ore. Another shaft has been started near the strike on the south tract, and construction of a new mill is to be started soon.

A fourth lease on 20 acres of land of the Lebanon Lead & Zinc Co. has been sold to the Red Bird Mining Co. for \$40,000. The selling company still holds the third lease, and sold the fourth lease on the land at an increase in royalty of 5%. The Lebanon associates sank only seven drill-holes on the lease, but these showed good faces of ore at the 165 and 190-ft. levels. The upper level showed low-grade ore, but the lower level showed ore that averaged as high as 11.20% from the drill-cuttings. The new company will sink a shaft. It also plans the construction of a 300-ton mill.

UTAH

SANPETE COUNTY

R. E. Knowlden, president and manager of the Sanpete Central Mining Co., reports that he is about ready to ship the first car of ore. This is a new property and consists of 8 claims located six miles west of Ephraim.

The ore is both sulphide and chloride and occurs mostly along a lime and sandstone contact, and assays from the ore now on the dump ready for shipment give returns of 34 to 42% lead, with 3 to 5 oz. in silver. Another car, which is nearly ready for shipment, will average about 18% lead and some silver, and there is blocked out several tons of the high-grade ore.

It is estimated that there is over 20,000 tons of low-grade ore that will pay fair returns if treated in a mill at the mine, and the company has in contemplation the putting in of Deister-Overstrom tables, Harz jigs, and other necessary machinery.

It will require the installing of an 800-ft. tramway to bring the ore down to the road where the mill will be erected, also the piping of water about 6000 ft., and a small pumping-plant to get the water to the mill, unless water can be developed on the premises, which is likely, Mr. Knowlden says.

The force of men at the property will be increased as fast as development requires.

Associated with Mr. Knowlden in the property are Adelbert Anderson, Harley Myers, Neils Mortenson, Jr., Anton Anderson, J. F. McCafferty, John Dyring, Andreas Olson, Leo Stevenson, and Mrs. Jacobson.

WASHINGTON

FERRY COUNTY

(Special Correspondence.)—The Knob Hill Mining Co. is excavating for the housing and installation of machinery for its new shaft, the sinking of which, to a depth of 500 ft., will begin about May 10. A gasoline-hoist will be used for the present, to be replaced later with more powerful machinery. The machine-drills will be supplied with air from the compressor at the old works. The site chosen for this new shaft is just east of the portal of the lower main adit. Cross-cuts will be driven from the new shaft to the main vein and the spurs from it, below the present workings. The 500-ft. level of the new workings will be approximately 700 ft. below the cropping of the Knob Hill vein. The company is still maintaining shipments of a carload of ore a day. After paying a \$10,000 dividend a reserve will be left of \$27,000, in addition to which 18 carloads are at the smelters or in transit, and yet to be settled for.

A 100-ton concentrating-plant has been authorized by the Galena Hill Mining Co. for its mine at Rock Cut, in the Orient district.

Republic, April 20.

STEVENS COUNTY

(Special Correspondence.)—Report says active operations will be resumed in May on the First Thought mine, in the Orient district.

It is reported that the Easter Sunday group of claims, situated between Orient and Northport, has been sold for \$250,000.

In the Copper Butte mine, on Toulou mountain, Orient district, 900 ft. in from the portal, stringers of copper ore are being passed through. Judging from the cropping, it is estimated that the main vein will be cut about 100 ft. farther in.

Orient, April 20.

NEW ZEALAND

The total production of minerals in New Zealand from January 1, 1853, to December 31, 1915, was valued at \$510,162,461, of which \$10,231,476 was accredited to 1915 production. Of the total, gold accounted for \$411,941,745. There were 8361 persons employed in the mining of metals in New Zealand during 1915.

An extensive bed of scheelite has been discovered in the southern part of New Zealand. It promises to become one of the richest mines of the mineral in this part of the world. A syndicate has been formed to push its development. Tungsten ores are known to occur in several places in the islands, but none of them is of greater promise than this.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

T. A. RICKARD is at Miami, Arizona.

JOHN H. EGGERS has gone to New Mexico.

FREDERICK W. GAY is back from New York.

BENJAMIN REZAS is again in San Francisco.

W. DE L. BENEDICT has returned to New York.

JACOB W. YOUNG has returned to State Creek, Alaska.

ALGERNON DEL MAR was in San Francisco during the week.

A. CHESTER BEATTY and family are touring in China and Japan.

J. MORGAN CLEMENTS passed through San Francisco bound for Tokyo.

STUART L. RAWLINGS is leaving San Francisco for Cerro de Pasco, Peru.

RALPH REGNALL is manager of the Dome Lake mine, Ontario, Canada.

PHILIP N. MOORE was in San Francisco and has gone to Spokane and Butte.

BRADLEY STOUGHTON passed through San Francisco on a tour of the Western States.

H. M. WOLFLIN has returned to San Francisco from the Mountain King mine in Mariposa county, California.

H. P. GORDAN has gone to Alaska to take charge of the Alaska Handy Gold Mining Company's property on Chichagoff island.

LIEUT. WILLIAM HAGUE, engineer corps, U. S. R., has been ordered into active service at the Presidio training camp, San Francisco.

L. WEBSTER WICKES is leaving Kingman, Arizona, to take charge of development of a copper property on the Ottawa river, Quebec.

JAY LOUEBMAN, who has been teaching mining engineering in the government university at Peking, is returning to America in May.

WILLIAM RICHARDS has gone from the Atolia mines to superintend the property of the Arizona Venture Mining Company in Mohave county, Arizona.

A. H. BABCOCK, consulting electrical engineer for the Southern Pacific company, has been commissioned major of engineers in the Reserve Corps of the Army.

WILLIAM H. LANDERS, formerly manager of the New Almaden quicksilver mines, has entered the training camp for the Officers' Reserve Corps at Plattsburg, New York.

Obituary

WILLIAM A. FARISH, a pioneer mining man of California, who for years was associated with the late Senator George Hearst, died in Los Angeles on May 4, upon returning from a mining trip into Arizona. Mr. Farish came to California from Tennessee in 1852, where he joined his father, who was engaged in the wool business in San Francisco. He attended school in San Francisco and Marysville, later going to work in the Sierra Buttes mine, in Plumas county, California. While owner of the Monumental mine in Sierra county he took out one of the largest nuggets ever found in California. He was associated with Senator Hearst in the Black Hills of South Dakota and acted for him in the purchase of several important mining claims afterward included in the Homestake Consolidation. He had large personal interests in various parts of the West. Mr. Farish is survived by a widow, two sons, and a daughter.

THE METAL MARKET

METAL PRICES

San Francisco, May 8

Antimony, cents per pound	23
Electrolytic copper, cents per pound	37
Pig lead, cents per pound	9.75-10.75
Platinum, soft and hard metal, per ounce	\$105-111
Quicksilver, per flask of 75 lb.	\$113
Spelter, cents per pound	12
Tin, cents per pound	58
Zinc-dust, cents per pound	20

ORE PRICES

San Francisco, May 8

Antimony, 50% metal, per unit	\$1.60
Chrome, 40% and over, f.o.b. cars California, cents per unit	50-55
Magnesite, crude, per ton	\$8.00-12.00
Tungsten, 60% WO ₃ , per unit	20.00
Molybdenite, per unit for MoS ₂ contained	40.00
Manganese, 45% (under 35% metal not desired), cents, unit	36-38

Buyers of manganese ore transact business on a basis of the long ton of 2240 lb., for which the present price is \$19 per ton for 45% ore. For each additional per cent 65c. is paid above the base rate, and the same deduction, of 65c., is made for each unit below 45%. Thus for an ore running 48% Mn the present price is \$19 + \$1.95 = \$20.95, and an ore containing 42% Mn is worth \$19 - \$1.95 = \$17.05. Ore running under 35% Mn is not wanted. A silica content up to 8% is permissible. A penalty of 50c. per unit is taxed on silica over 8%, up to 15%. If containing more than 15% the ore is not marketable.

Tungsten: On May 1 the new schedule for domestic tungsten ore came into operation and the Atolia Mining Co. is now quoting \$20 per unit on the basis of 60% WO₃ with 30c. added for every unit above. Thus high-grade ore, running about 65%, would command a price of \$21.50 and 70% as much as \$23. Anticipating this advance of price, buyers rushed to contract before the new schedule came into operation and the month of April has probably seen the largest business ever done during any thirty days in tungsten. The quantity disposed of in the New York market reached close to 1000 tons and contracts were closed to cover every month of this year. Eighteen dollars was just as readily paid for November deliveries as it was for prompt material. At the present moment, no ore of known and reliable assay is available for immediate delivery. The quantities of foreign ore on the way to New York of known assay have already been sold while afloat. Foreign ore in New York is mainly composed of ore, which, on account of its impurities, is not readily salable and such ore is commanding a price of about \$18 for prompt delivery. France and Italy have again appeared in our market as buyers for considerable quantities but have as yet not followed our advance, though the indications are that they will soon come into line again. The prospects of the tungsten market are exceedingly good and steady and it is anticipated that there will be a continuation of the prices now ruling for some time to come.

Manganese: The manganese position is unchanged. Buyers are anxious to pick up whatever lots are coming onto the market and to secure supplies contracts were entered into covering shipment for many months ahead. For 45% material 85c. would cover the present market quotation. Chemical ore, according to grade, is still quoted at 4½ to 6c. per lb. at New York.

EASTERN META MARKET

(By wire from New York)

May 8.—Copper is quiet but firmer at 31.50 to 32c. Lead is strong and higher at 10 to 10.25c. Spelter is steady at 9.37c. Platinum remains unchanged at \$105 to \$111.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date	Average week ending
May 2	74.67
3	75.12
4	75.12
5	75.12
6 Sunday	74.75
7	74.75
8	74.75

Monthly Averages

Scantiness of supplies of silver has been indicated by the movements of the price recently. So long as demand, other than that which is continually in force for coinage, continued insignificant and fitful, the London market remained inert, especially as the China exchange was falling and sales from that quarter were fairly constant. A little more general inquiry set in on March 31, and was accompanied by improving rates from China, with the result that the quotation rose sharply ½ to 3½d.; a further rise of 5/16d. was recorded on April 2, and the higher level has been fairly well maintained. The slight reaction may be attributed to general clearing up before the holidays.

The United States government bought 400,000 oz. during that week. This may be followed by further purchases.

It is stated officially that purchases made by the Secretary of State, and also locally in India, since February 1916, sufficed to provide 36 crores (224,000,000) of new rupees, a sum far exceeding the fresh coinage in any similar period since the re-commencement of the mintage of rupees 17 years ago. The total weight of silver represented is just under 123,500,000 oz., and, taking the average price of silver for the period (necessarily a rough method of calculation) the cost of purchase to the Indian government must have approximated £18,000,000 leaving a profit available for the Indian gold standard reserve of about \$8,000,000. As the stock of silver in the currency reserve shows during the period a net decrease of

over 4 crores, the amount of absorption exceeds 40 crores, an enormous sum, in about a year.

The last Indian currency returns show a moderate addition to the silver coin and bullion held in the reserve—the first time that this has occurred for three weeks.

The stock in Shanghai on March 31 consisted of about 30,600,000 oz. in cycee, and \$18,400,000 on March 24, 1917.

An interesting announcement appeared recently in the 'Times' to the effect that owing to the rise in the price of silver, the Italian government is authorizing the issue of 1 and 2-lire notes to the nominal value of £12,000,000. The hoarding of silver currency is prohibited.

Platinum is unchanged at \$105 for soft unalloyed metal and \$111 for the hard natural platinum-iridium alloy.

Eastern Metal Market

New York, May 2.

The question as to how much copper, lead, and zinc will be bought by the Government and by the Allies, and especially the price to be settled upon, are the controlling factors in the market which is generally a waiting one because of this uncertainty.

Copper, while still nominal and dull, had a spurt of activity last week.

Zinc also showed a renewal of interest and buying last week, but it is quiet again.

Lead is very strong and higher, with consumers doubtful as to whether there will be enough to go around after the Government has made its purchase.

Tin is unusually quiet but strong.

Antimony is easier and lower on larger supplies.

In the iron and steel market the Government's needs are also a dominating and deciding influence. At a meeting of steel makers on April 26 it developed that 610,000 tons of plates, shapes, and bars will be required for schedules already made up, while the year's requirements are estimated at 1,100,000 tons. The outstanding fact is that plans are shaping for purchases of iron and steel, copper, spelter, and lead by the United States government and the Allies in combination. It is believed, by informed persons, that prices will be paid which will maintain and not disturb present industrial conditions.

The April pig-iron output, according to telegraphic returns to *The Iron Age*, was the largest since October, having been 3,334,960 gross tons, or 111,165 tons per day, against 3,251,352 tons in March. The October rate was 113,189 tons per day. The present production-rate is close to 40,500,000 tons per year.

COPPER

The market continues in its normal rut. A show of life and strength manifested itself the middle of last week when inquiries were more numerous than for some time and some business was done. The cause of this condition was the report that the Government would pay not less than 25 to 26c. for any of its additional needs and that the Allies would pay the same or the market price for the last half, whatever that may be. This displaced some of the gloom and stagnation. At present the market is dull and nominal, and is a distinctly waiting one. Some large brokers believe that the Government will not pay a high price for the metal, and that, if it does, the same should hold true of other metals. It is understood that last week some unsold metal was offered at 26c. for the last half, with no takers. One large dealer yesterday quoted 26c. for third quarter delivery, but reported no business. The London quotation yesterday for spot electrolytic was £142, unchanged from last week.

LEAD

The lead market gains in strength as the days go by. The fact that the needs of the Government are to be very large indeed is fast becoming realized, though the actual figures are still a mystery. The market is difficult to describe. The question of the Government's needs has divided sentiment so that currents are crosswise. Some sellers declare that it is necessary to sell in order to prevent a runaway market. Others seem afraid to sell, deeming it their duty to fortify themselves so as to be able to provide a supply for the Government. The resulting condition is manifestly mixed and unsettled. It is conceded that the authorities will purchase a large amount. Some fear there will not be enough lead to go around. One net result has been a withdrawal from the market by some sellers, and more anxiety by some buyers. Purchases have been large, totaling 4000 to 5000 tons since this report was sent

a week ago. The delivery involved has been principally for June and July. Spot lead was almost unobtainable at one time, and some sales were reported at 10c., St. Louis, for May metal. The quotation yesterday was 9.75c., St. Louis, or 9.87½c., New York, for early delivery.

TIN

It is believed that buyers are well covered for their immediate needs since they show no anxiety and remain more or less aloof from the market. The week as a whole has been dull and quiet, and during the last three days the market seems to have come to a standstill, sales having amounted to not more than 50 tons a day on those days. The month started yesterday with almost no sales. Spot metal was quoted at 58.50c., the range for the week having been between 58 and 59c., New York, sales at the latter figure having been made on April 27. On April 30 about 25 tons of Straits in transit from London was sold at 57.50c. It is believed stocks are low, as a preliminary estimate of stocks on landing April 30 puts this at 1707 tons, though arrivals from Pacific ports to the East will not be known until May 10. Tin deliveries in April from Atlantic ports were 3800 tons, about the same as those in March. Arrivals May 1 were 100 tons, with the quantity afloat 2812 tons, or unchanged from last week. The London market has advanced, the quotation yesterday having been £230 2s.6d., or nearly £6 over that of a week ago. The average price for tin for the month of April was 55.82c., New York.

ZINC

In sympathetic, as well as psychological, influence with events in the copper market, the zinc market woke up from its stagnation last week and for a time manifested more animation than for two or three months. Possessed of the belief that the Government would cover its war needs at market rather than sub-market prices, consumers realized that spelter was cheap. Sales of considerable proportions were made last Thursday and Friday, mostly for delivery this side of July 1. Galvanizers were prominent buyers and other interests participated, as high as 9.50c., St. Louis, having been paid. This week the market is decidedly quiet and not much business is being done. The quotation is 9.25 to 9.50c., St. Louis, and not much further activity is expected until the Government's requirements and the price it is to pay are known. Awaiting developments is the slogan now for both sellers and buyers. The Government, in a preliminary statement, puts the March exports at 21,000 gross tons.

ANTIMONY

Arrivals of fair proportions of Chinese and Japanese metal overland from the West have decidedly eased the spot market, and this position is now quoted at 32 to 32.50c., New York. Considerable interest is shown in future shipments from the Orient.

ORES

TUNGSTEN. There has been heavy buying of concentrate reported in anticipation of the probable effect, on May 1, of the new quotation of the Atolia Mining Co. of \$20 per unit for 60% ore, with 30c. added for every unit over this. An estimate places the quantity sold at nearly 1000 tons for delivery all through the year, and at prices less than the new quotation. On the new scale high-grade ores running 65% would be quoted at \$21.50, and 70% ores at \$23 per unit. Ferro-tungsten has also advanced logically, or in anticipation, to \$2 to \$2.15 per lb. of contained tungsten. Demand is good.

MOLYBDENUM. With very little new ore appearing the situation remains as it was a week ago.

ANTIMONY. The nominal quotation is \$2.25 per unit, with the ore reported as quite scarce.

Company Reports

UTAH COPPER CO.

The twelfth annual report of the Utah Copper Co. for the year ended December 31, 1916, appears containing a large handsomely tinted panoramic view of the vast surficial steam-shovel workings of its great mine. It illustrates beautifully the successive benches, rising in steps of 30 to 40 ft., from the bottom of the canyons to the summit of the hill, a total difference in elevation of 1355 ft. There is also an elaborate contour-map showing the area of the company's property, and a cross-section indicating the various elevations and delineating the underground workings which comprise many thousand feet of levels and raises, with numerous bore-holes outlining the orebody.

The gross production of copper in concentrate, for the year, was 196,752,631 lb. The shipments of crude ore contained an additional 664,849 lb. After making smelter deductions the net production was 187,531,824 lb. In addition there was produced 47,648 oz. of gold, for which the company received \$20 an ounce, and 461,596 oz. of silver, which was sold for 66.68c. per oz. The net cost of all the copper produced was 6.95c. per lb. (6.612c. the previous year). Had it not been for the increased cost of labor and taxation, the cost per pound would have shown a substantial decrease, instead of an increase. The net operating profit amounted to \$33,747,739.50; dividends on investments and other income amounted to \$5,990,935.86. The total income or net profit available for dividends, or for other capital purposes, therefore, was \$39,738,675.36, or \$24.46 per share. Dividends were paid during the year as follows: March 31, at the regular rate then existing of \$1.50 per share and an extra dividend of \$1; June 30, a regular dividend of \$1.50 and an extra of \$1.50 per share; September 30, a regular dividend of \$1.50 and an extra of \$1.50 per share; December 30, a dividend at the newly established rate of \$2.50 per quarter, plus an extra of \$1 per share. The surplus remaining after dividends were paid was \$20,244,795.36. The total dividends paid to date aggregate \$52,215,777.50. The outstanding stock of the company remains unchanged, namely, 1,624,490 shares.

During the year no underground work was done in the Porphyry mine, but drifts and raises to the extent of 2619 ft. were driven in the Sulphide mine. One churn-drill hole was deepened in the porphyry orebody, and nine additional holes were drilled, the total of this work being 6906 ft. The combined length of the 96 holes drilled from the beginning of the development of the property up to the end of 1916, was 54,662 ft., corresponding to an average depth of hole of 569 feet.

Previous to 1917 there had been developed in the property 424,524,258 tons of ore, averaging 1.415% copper, of which quantity 270,000,000 tons is classed as fully developed, and 154,524,258 tons as partly developed. Prior to January 1, 1917, there had been mined from the property a total of 54,678,700 tons of ore averaging 1.449% copper, therefore the total reserve remaining amounts to 369,845,558 tons, averaging 1.41% copper. The year's addition to the reported reserve was 34,524,258 tons, which is 25,530,258 tons in excess of the quantity mined during the year.

The total amount of cap-rock removed during the year was 5,911,455 cu. yd. Previous to 1917, the total area over which stripping operations had been conducted was 226.61 acres, and the area completely stripped was 111.58 acres. Smelting-ore to the extent of 18,026 tons was mined by underground methods in the Sulphide mine. This ore contained copper, lead, and zinc. All of the concentrating copper ore was mined by steam-shovels, at a cost of 28.12c. per ton, of which 7.5c. represents the apportioned cost of stripping, and 0.38c. the charges for development. The actual direct cost of mining all the ore was

20.24c., as compared with 16.61c. during 1915, when the cost of labor and supplies was lower.

The equipment used in removing the cap-rock was increased by the addition of 50 standard-gauge, 30-yard all-steel air-dump cars. Other improvements at the mine consisted of extensions of the water-system supplying water to the locomotive and steam-shovel boilers; a few lodging-houses for employees, and a new compressor having a capacity of 3760 cu. ft. of free air per minute.

The total amount of ore milled at the Magna plant was 6,143,500 tons, and at the Arthur plant 4,850,500 tons, a total of 10,994,000 tons at the two plants. The Magna plant treated an average of 16,785 tons daily and at the Arthur plant, 13,253 tons daily. The average recovery at both plants was 62.34% of the assay value, but this low saving was due principally to the unusually large tonnage milled, and only in small part to the presence of unrecoverable carbonate. The normal capacity of the two plants is 20,000 tons daily, whereas during the year the average daily tonnage treated exceeded 30,000 tons. The cost of milling at Magna was 35.35c. per ton and at Arthur 40.94c. per ton, the average cost being 37.82c. The total gross production of copper contained in concentrate was 196,752,631 lb. and the average grade of the concentrate was 18.71% copper. The copper contained in the smelting-ore, which was shipped direct, was 664,849 pounds.

Total copper produced from all sources was 197,417,480 lb. The average cost per net pound of copper produced from concentrate, after making allowance for smelter deductions, and after crediting the precious-metal value and miscellaneous income in Utah, was 6.918 cents.

The new leaching-plant for oxidized ores is situated on the hillside, 1200 ft. south-east from the Magna mill. Construction work was started early in August, and all of the grading, as well as all of the concreting for six leaching-tanks, and part of the concreting for six additional ones, was completed before Christmas. It is estimated that the 12 tanks now being constructed will have a capacity of 3000 to 4000 tons daily. It is expected that they will be ready for operation early in the summer of 1917, but this depends on how rapidly the necessary equipment can be delivered. The plant is so situated that it can readily be enlarged to 10,000 tons per day. The material for which this plant is being constructed is the oxidized and partly oxidized cap-rock overlying the sulphide orebodies. The total estimated quantity of this material is 40,000,000 tons; about one-half of this quantity has been removed and is stored in stock-piles convenient for future recovery. The grade of this ore, so far as it can be determined pending actual leaching operations and sampling on a large scale, indicates an average copper content of 13 lb. per ton. Experiments extending over a period of years indicate that about 10 lb. per ton is soluble in dilute sulphuric acid, which is the lixiviation medium that will be used. These experiments also have demonstrated that about 9 lb. per ton can be actually recovered at a cost that probably will not exceed 9c. per lb. of copper recovered, and it may be considerably below that figure.

MYSOORE GOLD MINING CO. (LTD.)

The annual report of the Mysore Gold Mining Co. (Ltd.) for the year ended December 31, 1916, shows that 305,845 tons of ore was milled during the year, from which was recovered by amalgamation, 164,145 oz. of gold, being an average of 10 dwt. 17 gr. of gold per ton. There was also treated 239,877 tons of tailing for a return of 26,724 oz. gold, an average of 2 dwt. 5 gr. per ton, and 193,748 tons of slime produced 25,650 oz. of gold, an average of 2 dwt. 16 gr. per ton. The total production was 216,519 oz. of bar gold, equivalent to 197,245 fine ounces, of a realized value of £836,743, 8s.6d. The total production of the Mysore company to date (since September 1884) has been 215,239.99 oz. of fine gold. Total dividends paid, £8,390,344. 2s.2d.

Book Reviews

NOTES ON MILITARY EXPLOSIVES. By Erasmus M. Weaver, Maj. Gen. U. S. A., Chief of Coast Artillery. Fourth edition. Pp. 328 + viii. Wiley & Sons, New York. For sale by the *Mining and Scientific Press*. Price, \$3.25.

The author takes advantage of the exhaustion of the third edition of his well-known treatise to bring the work up to date by the inclusion of changes brought about by experience in the present European war. In his preface he says that the more important of these changes are the substitution of wood-pulp for cotton in the manufacture of nitro-cellulose explosives, and the fixation of the nitrogen of the air; that in general no new explosives have been introduced; that the field is limited to the nitro-cellulose series, the nitro-glycerine series, the nitro-benzene series, and the alkaline-metallic nitrate mixtures, singly or to a combination of two or more of these series with the others; that the great propellant explosive for guns continues to be nitro-cellulose alone, or in combination with nitro-glycerine; that the explosive for charging shells is definitely restricted to picric acid or its derivatives, and for submarine mines and torpedoes to tri-nitrotoluol (TNT), or to gun-cotton; that the old nitrate mixtures are limited to hand-grenades, rockets, and pyrotechnics.

To this edition has been added an essay by the Director of the Institute of Industrial Research, Washington, covering the basic chemical behavior of the four organic elements in all explosives.

Part I states briefly the fundamentals of chemistry, the more modern theories of the ultimate construction of matter being disposed of in a brief foot-note. Part II lists the various substances used in the manufacture of explosives and describes briefly their manufacture, their chemical and physical characteristics, and their actions. In part III the various explosives are classified for military purposes by their explosive phenomena, while in parts IV, V, and VI, the three principal classes of explosives are described in detail with respect to composition, manufacture, and behavior. Part VII treats of Service Tests, part VIII of storage of explosives, part IX of the handling of explosives, and part X of military demolitions.

In the appendices are tucked away some paragraphs of absorbing interest both to the professional student and to the lay seeker for information on this important subject. The Laboratory Notes are designed to start students by directing intelligent experimentation; the Government Rules for shipment of explosives have instructive value to all handlers of explosives; and the previously mentioned notes on the four organic elements contain also a description of the rôle played by the halogens, in gas-attacks, all of extraordinary interest at the present time. The chemistry of gas-bombs and gas-masks is briefly and clearly stated in untechnical language.

It is difficult to draw the line between those parts of the work most valuable to the scientist and to the soldier; for the thoughtful student-soldier will want to know all the brief theory herein set down, and the scientist should become interested in the practical handling and use of the finished product. Finally, the whole book is so simply and plainly written that even the general public may find much profit in a study of this work of an authority in the chemistry, manufacture, and practical handling in service of one of the most essential elements of warfare.—A. H. B.

DURING the last year large areas of land in Colorado, Utah, and Wyoming have been classified by the Department of the Interior as mineral land valuable for oil-shale. The lands so classified, except two small areas, one each in Colorado and Utah, which have been set aside as naval oil-shale reserves, are open to mineral entry under the mining laws of the United States and to non-mineral entry in accordance with the pro-

visions of the Act of July 17, 1914, the oil-shale deposits when entries are made under this act being reserved for separate acquisition under the mineral-land laws. In Wyoming approximately 460,000 acres has been classified as oil-shale land, and none of it has been included in a naval oil-shale reserve. The area underlain by oil-shale in Colorado and Wyoming and a small area near Watson, Utah, are shown on maps contained in United States Geological Survey Bulletin 641-F, a copy of which may be obtained free on application to the Director, United States Geological Survey, Washington, D. C. The oil-shale area in Utah will be shown on maps to be included in a report on the last season's field-work in that State.

Commercial Paragraphs

The SULLIVAN MACHINERY Co. has removed its office in Montreal to Toronto, Canada, at 37 Colborne street. Compressors and hammer-drills and their extra parts will be kept in stock there.

The SPRAY ENGINEERING Co., of Boston, Mass., has issued an interesting catalogue describing and illustrating the numerous spraying devices manufactured by that concern. It is known as Bulletin No. 501, and may be had on application.

J. G. Dawson, of Chicago, will commence immediately to remodel his mill near Sweetwater, Nevada. He has given the DENVER QUARTZ MILL & CRUSHER Co., of Denver, an order for some \$4000 worth of new equipment to be delivered by May 1.

The INGERSOLL-RAND Co., 11 Broadway, New York, has recently issued two new catalogues as follows: Form 3311, 20 pages, 6 by 9, covering the Imperial Type X duplex steam-driven compressors suitable for general industrial application of compressed air. The catalogue gives tables of sizes and capacities, and is thoroughly illustrated to show the machine in detail. Form 8507, 40 pages, 6 by 9, covers the Little David pneumatic drills. An endless number of various types and models are shown, with recommendations as to the particular character of work for which they are adapted. Each tool is illustrated and the several tables give the sizes and capacity of each tool. Copies of the above bulletin free on request at nearest branch office.

EDITORIAL

T. A. RICKARD, Editor

COPPER is said to have been exported to Europe during the month of April in enormous excess over immediate requirements. This has been criticized as an effort to advance prices and stimulate share-quotations. Whatever the motive, the result proves to have been advantageous in view of the growing difficulties in shipping a sufficient quantity of other supplies.

AGRICULTURAL annexes to mines are proposed in a formal resolution by the Mining and Metallurgical Society of America. Once more does the stress of war reveal our wasted opportunities and demand reform. The amount of water thrown upon the desert from Western mines and mills, would, if properly used for irrigation, produce food for many thousands of men.

IN this issue we publish a chart for correcting tape-measurements up to 500 feet. This was prepared by Mr. Walter S. Weeks, of the University of California, at the request of several mining engineers, who had found useful his chart for distances up to 200 feet, published, with an explanation, in our issue of October 28, 1916. We feel sure that many of our readers will appreciate, as we do, Mr. Weeks' courtesy in preparing this second chart.

GRADUATES of technical schools are now offered the opportunity to obtain commissions in the Corps of Engineers of the United States Army, putting such recruits on an even footing with graduates of the Military Academy at West Point. This is altogether the most desirable branch of the service for men specially fitted for an engineering career, as it offers a field for continued usefulness and advancement in a wide range of construction work falling within the province of the Army. The rigidity of the competitive examination required for acceptance has been so reduced as to make it comparatively easy for any young technical graduate of fair accomplishments to secure a commission.

THE Massachusetts Institute of Technology has effected an arrangement for conducting future research-work for the United States Smelting, Refining & Mining Co. at the laboratories of that institution. The trustees point out that this step is in the direction of forming closer relationships between the great technical schools and the industrial world in preparation for the commercial war that is to follow the present clash at arms. The only comment that the case seems to merit is that such mobilization of the great laboratories, as an aid in the industrial struggle soon to be renewed, is wise

and practical, and furthermore that it is another expression of a foregone conclusion among thinking men that the world is to gain nothing in rationalization of international industrial relationships as a result of the expiation of past errors in economic world-policy through the sacrifices now being made on the European battlefields.

COPIES of our issue of February 10 that were mailed to Europe went down on the 'Laconia' and the issue of February 24 appears also to have been the victim of submarine piracy. Incidentally, we may confess that our paper of October 9, 1915, or such copies of it as reached London, was confiscated by the British censor because we made a reference to the dropping of bombs on two buildings in London. We are glad to think, however, that we did no harm to the cause by our inadvertence.

IT is a phase of conservation, interesting if not new, that *The Daily Metal Reporter* credits to the Messrs. Guggenheim, a method of keeping in readiness to deliver lead to the Government. This consists in adding \$10 per ton to the price of spot lead. It is a most excellent scheme; if a little less metal is sold the net earning capacity of the smelting concern remains approximately stationary—its dividends are conserved at an undiminished level; whereas, if sales persist in being active, the higher price for raw material merely becomes figured into the ultimate cost of many diverse supplies, where a single item is lost in the avalanche of figures. As indicated before, the method lacks novelty, except in being proposed as an aid to the nation in its present crisis.

LAST week we recorded the death of William A. Farish, the news coming too late for more extended appreciation of his character and notable achievements. Coming, as he did, to California in the days of its golden glory, his schooling in practical mining on the great Mother Lode fitted him to render distinguished services in the opening of the untouched mineral resources of the West. Thus it happened that this Tennessee boy soon became identified with the famous bonanzas that have helped make the history of a score of commonwealths, the Sierra Buttes and Monumental in California, from which latter Farish took the largest nugget found in California up to 1870; the Father de Smet and the greater Homestake in the Black Hills where he was instrumental in establishing that premier mining operation for the late Senator Hearst; the Fryer Hill at Leadville; the Head Centre at Tombstone; and the mines of Cripple Creek, the importance of which Farish promptly recognized,

resulting in recommendations to the Midland railroad that caused the extension of that line into the district. His activities touched every important mining camp in the West, and few men have been more widely known and esteemed as able pioneers in the development of our mineral resources. His brother, Mr. John B. Farish, whose name is intimately connected with the mining world, is now living in San Francisco.

PRESIDENT MOORE of the American Institute of Mining Engineers, addressing the May meeting of the San Francisco Section, urged that the question of raising the standard for admission to the Institute be given serious consideration. This has long been desired, and when a definite aim is set up a feasible means of attaining it can generally be found. The problem is not difficult when the officials express the sentiments of the rank and file, as we believe they will be found to have done in this instance. Mr. Moore's plan is simple and practical; he would merely raise the standard for the future. That would in no wise effect the status of the present members, nor would it introduce the jealousies of an aristocratic inner circle. It is in line with the spirit of growth and progress that means better adaptation to the purposes of a scientific association. No greater reason can be adduced for maintaining the wide-open door to membership that was offered when the Institute was founded than for holding the entrance requirements of a Western mining school at its pioneer level after the standards of culture and training had swept onward with a developing State.

INTENSIVE development of deposits of sulphide ore is urged by the Department of the Interior, for the sake of the incidental accumulation of larger resources of sulphur in the interior of the country. This is an important measure, and will doubtless stimulate sulphuric-acid companies that are not active bidders at present for mixed sulphide ores to enter the market. In no other way could a large demand for such complex ores be so quickly created as by utilizing the facilities existing at acid-plants, which could be made available for treating them with comparatively slight modifications or additions to the equipment already installed. This would encourage the development more particularly of complex ores containing abundant pyrite. Iron sulphide is difficult to separate from the accompanying minerals by selective flotation, but it gives the concentrate the necessary free-burning qualities for roasting in the ordinary Wedge and Herreshoff furnaces commonly used at sulphuric-acid plants. The tendency among acid-manufacturers during the last two years to resort to sulphur-burners, with the disadvantages incident upon using sulphur as compared with pyritic ore, accentuates the wisdom of such an expansion of the scope of operations of acid-making concerns in conjunction with the more energetic production of sulphide ores as proposed from considerations of military necessity by the authorities at Washington. The urgency of the situation is revealed by the fact that importations of pyrite from Spain have ceased, owing to

lack of shipping facilities. The utilization of complex sulphides at acid-plants would assist materially in overcoming the difficulty.

The Building of Ships

Ships are to win the War, we are told. Most assuredly without ships in sufficient number we will not win it. Lord Eustace Percy of the British foreign trade department has affirmed that "if Prussianism is to be crushed, there must be ships, ships, and more ships," adding that the German submarines are sinking British tonnage faster than it can be turned out in British yards. In view of the contradictory statements that have been published regarding the intention of our Government to construct a thousand wooden vessels, it is our privilege to state that plans for a standard ship, which can be turned out wholesale after the fashion of building Ford automobiles, are nearly complete, representing a Herculean achievement considering the shortness of the time that has elapsed since the work of designing was undertaken. Meanwhile necessary materials have been secured lest they should be absorbed for other purposes, and assembly of these supplies at various points is being made. The equipment for motive power that could be provided within a proper time has already been investigated, and contracts let; there will be no delay in the delivery of this prime essential. A contract has been awarded to The Foundation Company of New York for a large number of these vessels having a displacement of 3500 tons each, and preparations for their construction are being made on Newark bay, under the direction of Mr. Franklin Remington. Similar preparations are under way at Portland, Oregon, and at Oakland, California. It is also understood that the Government has found an unexpectedly large supply of suitable air-dried timber available, so that the criticism of the plan, based on the scarcity of such structural material, proves to have been without foundation. Lake copper in large quantities will be rolled for properly sheathing the boats, which are to be built with a view to a life of 30 years. The amount of copper required for 1000 ships will be approximately 27,000,000 pounds, exclusive of copper fasteners, bolts, and rivets.

The labor question at first seemed to be a serious problem, but the decision to standardize the parts offers a means of overcoming the difficulty, as it is an easy matter to train carpenters to do piece-work following an unvarying pattern. The 15,000 expert ship-carpenters, working in conjunction with an army of other carpenters turning out special parts, will meet the necessities of the case. The objection offered in some quarters to the building of wooden ships on the ground that steel vessels could be constructed at practically the same speed, has been anticipated by enlisting every facility in the country for the construction of the normal modern type of merchantman, and by providing additional ways at the ship-yards as rapidly as possible for increasing the number that can be built simultaneously. It is stated that a

standard 5000-ton steel vessel, drawing 20 feet of water, has been adopted for this class of contribution to the urgent need of shipping. If not ready for service as quickly as the wooden ships, they will soon be available for supplementing losses by submarine attack, and those that survive the War will then be useful for trading to many South American ports where shallow draught offers an advantage on account of a common lack of deep harbors.

Criticism of the Government's plan to provide emergency ships is not justified at the present moment. They must be built, and that means, in this resourceful country, that they will be built. The evidence at hand indicates that no overwhelming difficulties have been encountered, and the work is in charge of Major General George W. Goethals who has won the confidence of the nation by doing big and difficult things in the past. He did not fail to build the Panama Canal on schedule time; neither will he fail to make ready the ships that the country needs.

Freedom of the Press

Censorship is a matter of concern in every department of life; it affects every industry. Censorship upon criticism will not, as some profess, remove obstructions to the free course of Government in effectively carrying out its programme; it will rather allow the sand and dirt to accumulate over the administrative machinery until the bearings are clogged and the hot-boxes bring trouble. If criticism be not exactly a lubricant, it is at least a most excellent besom to keep the works clean. We have welcomed a certain kind of censorship, but the politicians have gone after something wholly different. They have sought to muzzle the press; to surround authority with the halo of impeccability, which savors not of democracy. The argument of sensationalism has been used against the press to trick the public into acquiescence, and this, it must be confessed, is to attack the press at the spot where the linden leaf fell upon it. Nevertheless, the argument is one that confuses the issue. A considerable part of the American press has indeed become yellow, but the color has been given chiefly through the untrustworthiness of its news. Theory, opinion, criticism, have no power to harm when they contravene known facts. False argument cannot survive the truth if the truth be let out. It is when news that is offered as fact is actually a lie, that sensationalism leads the nation to error in thought and action. If the Government desire effective aid from an intelligent people its best endeavor might be directed toward means for making the press eager to obtain only truthful news, and this could readily be accomplished by creating a news-standard based upon a censorship that shall go no further than to put the seal of verification upon such dispatches as can be guaranteed by the censor to be true. If the public could be given assurance, both through the limitations set by the statute and because of the reliability of the censorship board, that the question of simple accuracy, untingered

by considerations of party policy, would govern the decision of the censor, every other dispatch lacking that guarantee would labor under the suspicion of being incorrect. To kill sensationalism, put an authoritative stamp of truth on that which is true, and it will automatically compel the newspapers to strive after a reputation for verity that shall make their own editorial sanction as valid as the official endorsement. A people fed on truth will think honestly; a people conceded the right to know all the truth excepting only those concerning bureaucratic plans and procedure that would give comfort to the enemy if divulged, will be a people certain to rally with enthusiasm to the support of the Government, and to give all that it has of brain-power and goodwill, of purse, labor, and life itself, in the high efficacy of deep moral conviction and devotion. A democracy kept in the dark, feeling that its news is censored not with a view to giving the truth but for the purpose of suppressing it, and perhaps of misleading by methods not wholly unlike those that have made the yellow press so reprehensible, is a people chained as is that people whom we have pledged to deliver from their autocrat.

We of the mining world deal with the facts of vital supplies that give sinews to the nation for fighting its battles; we disseminate knowledge of methods for winning the ores and for winning the metal out of the ores; it also becomes our obligation to take account of metal markets and of conditions that determine a just and patriotic distribution of the products of mine and smelter for the common good. If we may not speak the truth we then fail in our duty of aiding by information and suggestion in the co-ordinating of the mineral industries for national service. There is a right and a wrong use of censorship. It will be a disaster if anything more is attempted than to put the official fiat on news that is true, to leave it off if the item is not shown to be correct, to require the mark of approval to be printed with news that has passed muster, and to let the laws against treason take care of traitorous utterances. A strong government adds to its strength by enlisting the criticism of those used to the study of public affairs.

Labor in Mining

In this issue we publish an interview with a veteran of the profession, Henry C. Perkins, one of the engineers to achieve distinction in the period when Hamilton Smith and his friends were leaders in the business of gold mining. The mines in which he obtained his first experience, the Mariposa and the Almaden, are still active and the mention of them recalls the fact that many members of the profession served their apprenticeship at these famous properties. Mines are places where men as well as lodes are developed. New Almaden, more particularly, enabled Henry C. Perkins, Hennen Jennings, James B. Randol, Samuel B. Christy, Charles Butters, F. W. Bradley, and E. H. Benjamin to cut their wisdom teeth comparatively early in life. The quicksilver mines

made money for their owners, but even if they had not done so they would have declared human dividends of a kind that money does not measure. The engineering work done at the North Bloomfield represented a notable achievement of the early days; it included several miles of bedrock-adit, big dams, and long pipe-lines; it was all done at a moderate cost and so well that it compares favorably with similar work in more recent years. It is pleasant to read the tribute paid by Mr. Perkins to Hamilton Smith. The latter was not only an engineer of fine acumen and high character but by his association with the Rothschilds he helped to introduce many young Americans to a wider career than California by itself would have offered. It must be remembered that 40 years ago the mining industry of the United States was of small dimensions compared with what it is now, and an ambitious engineer was lucky to obtain an opportunity abroad. The El Callao mine, in Venezuela, furnished experience to a large number besides Mr. Perkins and Hamilton Smith; for example, there were Hennen Jennings, Thomas Mein, George Webber, and W. L. Austin. None of them learned more from his sojourn there than Mr. Perkins himself. He tells us two of the things he learned: that straight dealing is the best policy even with crooked people, and that human beings as workers are much the same the world over if they are given a chance. He does not say much about the 'bluffs' that he 'called' while he was manager of the El Callao, but we have heard how mining inspectors, governors, even Guzmán Blanco himself, found it useless to blackmail or bulldoze the quiet young American who attended strictly to his business and assumed that others would do likewise. Nothing is so disconcerting to South American indirection as North American directness. Concerning the labor question he has more to say, and it is highly interesting. His experience in California, Venezuela, Mexico, South Africa, and Korea, among the districts in which he supervised mining operations, appears to have furnished him with decided ideas on the subject. We accept them as coming from a man wise rather than smart, sagacious more than merely clever. To the younger men we commend the advice to employ the indigenous population of a mining district, teaching them and handling them sympathetically, instead of importing labor from outside, more particularly workmen that are foreign in race and speech. To take high-priced American labor to Korea or Rhodesia, for example, instead of training and teaching the natives of either country, is the kind of mistake that has been made often both by British and American mine-managers. The disregard of this fundamental idea, of making the most use of the indigenous population, was the basic objection to the importation of Chinese into the Transvaal. The system of indenture succeeded up to a point, but that point was not passed, because the experiment was ended summarily; but if the Chinese had stayed it would have given the Transvaal a hybrid population, and it would have delayed the development of the Kaffir as a mine-worker. Mr. Perkins put his idea to work in

Korea, with notable success. He gives some comparative figures, suggesting that the rate of wages does not determine the cheapness of exploitation; on the contrary, the cheapest labor may prove the least economical. The comparison between the three mining districts of the Mysore, Korea, and the Rand is suggestive. To what extent a systematic effort has been made to educate the natives on the Kolar goldfield we do not know, but those Indian mines have been highly productive so long that any serious attempt to train the natives would have come to fruition by this time. In this district, as on the Rand, the employment of an excessive number of imported white supervisors is a heavy item of cost, and goes far to discount the effect of paying low wages to run-of-mine labor.

The first appointment obtained by Mr. Perkins was as a book-keeper. It is evident that his early experience in book-keeping proved of the greatest usefulness, because it gave him a keen realization of the fact that the profit of mining is dependent as much upon diminution of cost as increase of yield. The system of accounts in use at a number of important mines on the Western slope is based on the book-keeping developed by Mr. Perkins at the North Bloomfield and Alaska Treadwell mines. His own success as a mining engineer is largely due to his ability to analyze figures. Thus did an early training bear fruit in after years. The reference to sampling in Korea touches upon a controversial point, namely, to what extent regular sampling with a moil and hammer can be accepted as a decisive factor in estimating the prospects of a mine. Mr. Perkins found gold in patches distributed irregularly in a group of quartz veins. The workings were unsystematic and the rich spots had been gouged. He found it safest to appraise the mines by making an estimate of the yield of gold per square foot of vein on the supposition that the ore, when worked on a larger scale, would be extracted continuously and without selection. The bigger operations that he had in mind could not be based upon the hunting of pockets or patches. His forecast has been justified. The Oriental Consolidated has proved an important gold mine, the dividends aggregating \$7,500,000. His remarks on the Japanese occupation are friendly and fair. We infer that new American enterprise in Korea will not have as much chance in the future as in the past. In another part of the interview he expresses a decided opinion that any advance in mining economy must come through an intelligent and sympathetic study of labor conditions, of the relation between employer and employee. He warns us against the continued raising of wages and suggests that the best results will be obtained by profit-sharing. This is good advice. In regard to the making of fortunes, speculation in shares, and publicity of company affairs, Mr. Perkins speaks with a sagacity that comes of keen observation and unbiased thinking. The older men have their own opinions and are not likely now to alter them, but we invite our younger readers to study the sayings of this distinguished veteran.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Amortization and Depreciation

The Editor:

Sir—In your issue of September 23, 1916, an article appears by Robert S. Lewis on this subject. Both the subject-matter and the article are interesting, and the issue raised is important. With regard to depreciation, much of what the author writes is sound, and I believe will be approved by nearly all competent men connected with mining. I cannot, however, agree with part of what he writes. With regard to amortization, I disagree almost entirely with the article. I write this to submit the way in which I see these matters.

With regard to the use of more or less complicated mathematical formulas to express either depreciation or amortization, I consider that these are unnecessary and unsuitable, at least in the case of nearly all metal-mining business. The premises on which the formula can be based are uncertain in varying degree—in many cases highly uncertain; in other words, the figures or estimates to which the formula must be applied are assumptions only, and in only a minority of cases will they prove to be even approximately correct. In passing, it appears to me that there is a tendency in some quarters to apply formulas to too great an extent in other mining work.

If we accept the view that sinking funds for return of capital and for depreciation ought to be created and, further, that the bases for adding to these ought to be determined ahead, that is, that in each case a certain number of years should beforehand be accepted as the period in which to accumulate certain agreed amounts and, again, that the periodical payments to the funds should be equal, then formulas are useful and even necessary. But I submit that the above view is not logical. The continually changing circumstances (including the purchasing power of money) make the said bases too rigid.

The use of formulas certainly costs nothing and can do no direct harm. I submit, however, that their use may tend to a wrong view being taken of the affairs to which they are applied, the tendency being to cause assumptions to be regarded as established facts. I submit that there are more logical, more elastic, and more business-like ways of dealing with these matters.

It appears to me that the question of amortization is essentially one for individual preference. It is right if those concerned elect to adopt it. That it has any other claim to being correct finance, I cannot see. A reason given is, that of the large number of stockholders in mining shares few understand the real nature of their

income and provide accordingly. The reply to this is that it should be the business of the directors to see that the stockholders do understand the real nature of their incomes. It seems to me that it is just such matters for which they are appointed trustees by the stockholders.

In any case, amortization can only become a serious protection after a considerable number of years. During the early years, that constitute the most critical period for most mines, the protection is only incomplete and in varying degrees. It is claimed that some mining companies are practically amortizing their capital in order to prolong their lives, the end of their mines being in sight. This is not amortizing their capital. It is forming a reserve for the object specified. The use of the money so reserved in further mining (or other speculative business) is contrary to the idea of amortization, which is to retain intact the principal invested. As to whether the making of such a reserve for such a purpose is right or correct is again entirely a matter for those concerned. As to whether it is good business will depend entirely on circumstances and will be known only subsequently by results in each case. An abuse of such a practice is obvious. For instance, a board of directors, seeing the end of their fees in sight, would be tempted to use such a reserve in order to keep things going even if the prospects available to them at the time did not really justify the expenditure. It is not inferred that all boards would so act, but that the temptation would be there. In many cases a bias (conscious or unconscious) would exist and in some—let us hope a few only—no doubt there would be deliberate bias. It would not follow because a man invested in a certain mine that he would wish to have part of his returns therefrom used in such a way, and he would have a good right to object to it.

If it be decided in certain cases to establish such a fund, it would be more consistent and business-like not to fix a sum to be paid annually but to decide periodically what sum to allocate to the fund, all circumstances being considered. Presumably in such case if, as time went on, the mine showed promise of longer or shorter life, then the sum allocated on any one occasion would be smaller or larger respectively. Other changing factors would similarly be allowed for.

In cases where it is not desired to form such a fund, and if it be considered that many of the stockholders are ignorant of the real nature of their incomes, and that some protection should be given them on this score, I would suggest that the divisible profit (dividends)

should be paid in two lots, one to be regarded as income and one as return of capital. If stockholders thereafter regarded their total receipts as income they would certainly have no excuse for so doing. Personally, I do not believe that such action is necessary. Proper periodical explanations as to the real nature of dividends would, I consider, meet the case.

I submit then that amortization is not necessary to sound finance, and further that if it be decided by some to form a sinking-fund for the purpose either of keeping the invested capital intact at the finish of the mine or of prolonging the life of the company by securing new property, the logical way of dealing with the matter is not the application of rigid formulas, but rather the periodical appraisal of the situation and allocations based on judgment. The basis on which allocations are made are in most cases constantly changing. It is more suitable and logical that the allocations should also be decided upon by periodical judgments.
